# Table of Contents

<b>Preface .....</b>	<b>xliii</b>
1. What is PostgreSQL? .....	xliii
2. A Brief History of PostgreSQL.....	xliv
2.1. The Berkeley POSTGRES Project .....	xliv
2.2. Postgres95.....	xliv
2.3. PostgreSQL.....	xliv
3. Conventions.....	xlvi
4. Further Information .....	xlvi
5. Bug Reporting Guidelines.....	xlvi
5.1. Identifying Bugs .....	xlvi
5.2. What to report.....	xlvi
5.3. Where to report bugs .....	xlv
<b>I. Tutorial.....</b>	<b>1</b>
1. Getting Started .....	1
1.1. Installation .....	1
1.2. Architectural Fundamentals.....	1
1.3. Creating a Database.....	2
1.4. Accessing a Database .....	3
2. The SQL Language .....	6
2.1. Introduction .....	6
2.2. Concepts .....	6
2.3. Creating a New Table .....	6
2.4. Populating a Table With Rows .....	7
2.5. Querying a Table .....	8
2.6. Joins Between Tables.....	10
2.7. Aggregate Functions.....	12
2.8. Updates .....	14
2.9. Deletions.....	14
3. Advanced Features .....	16
3.1. Introduction .....	16
3.2. Views .....	16
3.3. Foreign Keys.....	16
3.4. Transactions.....	17
3.5. Inheritance .....	19
3.6. Conclusion.....	21
<b>II. The SQL Language.....</b>	<b>22</b>
4. SQL Syntax .....	24
4.1. Lexical Structure.....	24
4.1.1. Identifiers and Key Words.....	24
4.1.2. Constants.....	25
4.1.2.1. String Constants .....	25
4.1.2.2. Dollar-Quoted String Constants .....	26
4.1.2.3. Bit-String Constants .....	27
4.1.2.4. Numeric Constants .....	28
4.1.2.5. Constants of Other Types .....	28

4.1.3. Operators.....	29
4.1.4. Special Characters.....	30
4.1.5. Comments .....	30
4.1.6. Lexical Precedence .....	31
4.2. Value Expressions.....	32
4.2.1. Column References.....	33
4.2.2. Positional Parameters.....	33
4.2.3. Subscripts.....	33
4.2.4. Field Selection .....	34
4.2.5. Operator Invocations.....	34
4.2.6. Function Calls .....	35
4.2.7. Aggregate Expressions.....	35
4.2.8. Type Casts .....	36
4.2.9. Scalar Subqueries.....	37
4.2.10. Array Constructors.....	37
4.2.11. Row Constructors.....	38
4.2.12. Expression Evaluation Rules .....	40
5. Data Definition.....	41
5.1. Table Basics.....	41
5.2. Default Values .....	42
5.3. Constraints.....	43
5.3.1. Check Constraints .....	43
5.3.2. Not-Null Constraints.....	45
5.3.3. Unique Constraints.....	46
5.3.4. Primary Keys.....	47
5.3.5. Foreign Keys .....	48
5.4. System Columns.....	50
5.5. Modifying Tables.....	52
5.5.1. Adding a Column.....	52
5.5.2. Removing a Column .....	53
5.5.3. Adding a Constraint .....	53
5.5.4. Removing a Constraint .....	53
5.5.5. Changing a Column's Default Value.....	54
5.5.6. Changing a Column's Data Type .....	54
5.5.7. Renaming a Column .....	54
5.5.8. Renaming a Table .....	54
5.6. Privileges .....	55
5.7. Schemas.....	55
5.7.1. Creating a Schema .....	56
5.7.2. The Public Schema .....	57
5.7.3. The Schema Search Path.....	57
5.7.4. Schemas and Privileges.....	59
5.7.5. The System Catalog Schema .....	59
5.7.6. Usage Patterns.....	59
5.7.7. Portability.....	60
5.8. Inheritance .....	60
5.8.1. Caveats.....	63
5.9. Partitioning .....	63

5.9.1. Overview .....	63
5.9.2. Implementing Partitioning .....	64
5.9.3. Managing Partitions .....	67
5.9.4. Partitioning and Constraint Exclusion .....	68
5.9.5. Alternative Partitioning Methods .....	69
5.9.6. Caveats .....	70
5.10. Other Database Objects .....	71
5.11. Dependency Tracking .....	71
6. Data Manipulation .....	73
6.1. Inserting Data .....	73
6.2. Updating Data .....	74
6.3. Deleting Data .....	75
7. Queries .....	76
7.1. Overview .....	76
7.2. Table Expressions .....	76
7.2.1. The FROM Clause .....	77
7.2.1.1. Joined Tables .....	77
7.2.1.2. Table and Column Aliases .....	80
7.2.1.3. Subqueries .....	82
7.2.1.4. Table Functions .....	82
7.2.2. The WHERE Clause .....	83
7.2.3. The GROUP BY and HAVING Clauses .....	84
7.3. Select Lists .....	86
7.3.1. Select-List Items .....	86
7.3.2. Column Labels .....	87
7.3.3. DISTINCT .....	87
7.4. Combining Queries .....	88
7.5. Sorting Rows .....	88
7.6. LIMIT and OFFSET .....	89
7.7. VALUES Lists .....	90
8. Data Types .....	92
8.1. Numeric Types .....	93
8.1.1. Integer Types .....	94
8.1.2. Arbitrary Precision Numbers .....	94
8.1.3. Floating-Point Types .....	95
8.1.4. Serial Types .....	97
8.2. Monetary Types .....	97
8.3. Character Types .....	98
8.4. Binary Data Types .....	100
8.5. Date/Time Types .....	102
8.5.1. Date/Time Input .....	103
8.5.1.1. Dates .....	103
8.5.1.2. Times .....	104
8.5.1.3. Time Stamps .....	105
8.5.1.4. Intervals .....	106
8.5.1.5. Special Values .....	106
8.5.2. Date/Time Output .....	107
8.5.3. Time Zones .....	108

8.5.4. Internals.....	110
8.6. Boolean Type.....	110
8.7. Enumerated Types .....	111
8.7.1. Declaration of Enumerated Types.....	111
8.7.2. Ordering .....	111
8.7.3. Type Safety .....	112
8.7.4. Implementation Details.....	113
8.8. Geometric Types.....	113
8.8.1. Points .....	113
8.8.2. Line Segments.....	114
8.8.3. Boxes.....	114
8.8.4. Paths.....	114
8.8.5. Polygons.....	115
8.8.6. Circles .....	115
8.9. Network Address Types.....	115
8.9.1. <code>inet</code> .....	116
8.9.2. <code>cidr</code> .....	116
8.9.3. <code>inet</code> vs. <code>cidr</code> .....	117
8.9.4. <code>macaddr</code> .....	117
8.10. Bit String Types.....	117
8.11. Text Search Types.....	118
8.11.1. <code>tsvector</code> .....	118
8.11.2. <code>tsquery</code> .....	119
8.12. UUID Type .....	120
8.13. XML Type .....	121
8.13.1. Creating XML Values .....	121
8.13.2. Encoding Handling .....	122
8.13.3. Accessing XML Values.....	123
8.14. Arrays .....	123
8.14.1. Declaration of Array Types.....	123
8.14.2. Array Value Input.....	124
8.14.3. Accessing Arrays .....	125
8.14.4. Modifying Arrays.....	127
8.14.5. Searching in Arrays.....	129
8.14.6. Array Input and Output Syntax.....	130
8.15. Composite Types .....	131
8.15.1. Declaration of Composite Types.....	132
8.15.2. Composite Value Input.....	133
8.15.3. Accessing Composite Types .....	133
8.15.4. Modifying Composite Types.....	134
8.15.5. Composite Type Input and Output Syntax.....	135
8.16. Object Identifier Types .....	136
8.17. Pseudo-Types.....	137
9. Functions and Operators .....	139
9.1. Logical Operators .....	139
9.2. Comparison Operators.....	139
9.3. Mathematical Functions and Operators.....	141
9.4. String Functions and Operators.....	144

9.5. Binary String Functions and Operators .....	156
9.6. Bit String Functions and Operators .....	158
9.7. Pattern Matching .....	159
9.7.1. LIKE .....	159
9.7.2. SIMILAR TO Regular Expressions .....	160
9.7.3. POSIX Regular Expressions .....	161
9.7.3.1. Regular Expression Details .....	165
9.7.3.2. Bracket Expressions .....	167
9.7.3.3. Regular Expression Escapes .....	168
9.7.3.4. Regular Expression Metasyntax .....	171
9.7.3.5. Regular Expression Matching Rules .....	172
9.7.3.6. Limits and Compatibility .....	173
9.7.3.7. Basic Regular Expressions .....	174
9.8. Data Type Formatting Functions .....	174
9.9. Date/Time Functions and Operators .....	180
9.9.1. EXTRACT, date_part .....	185
9.9.2. date_trunc .....	188
9.9.3. AT TIME ZONE .....	189
9.9.4. Current Date/Time .....	190
9.9.5. Delaying Execution .....	191
9.10. Enum Support Functions .....	192
9.11. Geometric Functions and Operators .....	193
9.12. Network Address Functions and Operators .....	197
9.13. Text Search Functions and Operators .....	199
9.14. XML Functions .....	204
9.14.1. Producing XML Content .....	204
9.14.1.1. xmlcomment .....	204
9.14.1.2. xmlconcat .....	204
9.14.1.3. xmlelement .....	205
9.14.1.4. xmlforest .....	206
9.14.1.5. xmlpi .....	207
9.14.1.6. xmlroot .....	207
9.14.1.7. XML Predicates .....	208
9.14.2. Processing XML .....	208
9.14.3. Mapping Tables to XML .....	209
9.15. Sequence Manipulation Functions .....	212
9.16. Conditional Expressions .....	214
9.16.1. CASE .....	214
9.16.2. COALESCE .....	216
9.16.3. NULLIF .....	216
9.16.4. GREATEST and LEAST .....	217
9.17. Array Functions and Operators .....	217
9.18. Aggregate Functions .....	219
9.19. Subquery Expressions .....	222
9.19.1. EXISTS .....	222
9.19.2. IN .....	223
9.19.3. NOT IN .....	223
9.19.4. ANY/SOME .....	224

9.19.5. ALL .....	224
9.19.6. Row-wise Comparison .....	225
9.20. Row and Array Comparisons .....	225
9.20.1. IN .....	225
9.20.2. NOT IN .....	226
9.20.3. ANY/SOME (array) .....	226
9.20.4. ALL (array) .....	226
9.20.5. Row-wise Comparison .....	227
9.21. Set Returning Functions .....	228
9.22. System Information Functions .....	229
9.23. System Administration Functions .....	236
10. Type Conversion .....	243
10.1. Overview .....	243
10.2. Operators .....	244
10.3. Functions .....	247
10.4. Value Storage .....	250
10.5. UNION, CASE, and Related Constructs .....	251
11. Indexes .....	253
11.1. Introduction .....	253
11.2. Index Types .....	254
11.3. Multicolumn Indexes .....	255
11.4. Indexes and ORDER BY .....	256
11.5. Combining Multiple Indexes .....	257
11.6. Unique Indexes .....	258
11.7. Indexes on Expressions .....	258
11.8. Partial Indexes .....	259
11.9. Operator Classes and Operator Families .....	262
11.10. Examining Index Usage .....	263
12. Full Text Search .....	265
12.1. Introduction .....	265
12.1.1. What Is a Document? .....	266
12.1.2. Basic Text Matching .....	267
12.1.3. Configurations .....	268
12.2. Tables and Indexes .....	268
12.2.1. Searching a Table .....	268
12.2.2. Creating Indexes .....	269
12.3. Controlling Text Search .....	270
12.3.1. Parsing Documents .....	271
12.3.2. Parsing Queries .....	272
12.3.3. Ranking Search Results .....	273
12.3.4. Highlighting Results .....	275
12.4. Additional Features .....	276
12.4.1. Manipulating Documents .....	276
12.4.2. Manipulating Queries .....	277
12.4.2.1. Query Rewriting .....	278
12.4.3. Triggers for Automatic Updates .....	280
12.4.4. Gathering Document Statistics .....	281
12.5. Parsers .....	282

12.6. Dictionaries.....	283
12.6.1. Stop Words.....	285
12.6.2. Simple Dictionary .....	285
12.6.3. Synonym Dictionary .....	287
12.6.4. Thesaurus Dictionary .....	287
12.6.4.1. Thesaurus Configuration .....	288
12.6.4.2. Thesaurus Example .....	289
12.6.5. Ispell Dictionary.....	290
12.6.6. Snowball Dictionary .....	291
12.7. Configuration Example.....	291
12.8. Testing and Debugging Text Search .....	293
12.8.1. Configuration Testing.....	293
12.8.2. Parser Testing.....	295
12.8.3. Dictionary Testing.....	296
12.9. GiST and GIN Index Types .....	297
12.10. psql Support.....	299
12.11. Limitations.....	302
12.12. Migration from Pre-8.3 Text Search.....	302
13. Concurrency Control.....	304
13.1. Introduction .....	304
13.2. Transaction Isolation .....	304
13.2.1. Read Committed Isolation Level .....	305
13.2.2. Serializable Isolation Level.....	306
13.2.2.1. Serializable Isolation versus True Serializability .....	307
13.3. Explicit Locking .....	308
13.3.1. Table-Level Locks.....	308
13.3.2. Row-Level Locks .....	310
13.3.3. Deadlocks.....	311
13.3.4. Advisory Locks.....	312
13.4. Data Consistency Checks at the Application Level.....	313
13.5. Locking and Indexes.....	313
14. Performance Tips .....	315
14.1. Using <code>EXPLAIN</code> .....	315
14.2. Statistics Used by the Planner .....	320
14.3. Controlling the Planner with Explicit <code>JOIN</code> Clauses.....	321
14.4. Populating a Database .....	323
14.4.1. Disable Autocommit .....	323
14.4.2. Use <code>COPY</code> .....	323
14.4.3. Remove Indexes .....	324
14.4.4. Remove Foreign Key Constraints .....	324
14.4.5. Increase <code>maintenance_work_mem</code> .....	324
14.4.6. Increase <code>checkpoint_segments</code> .....	324
14.4.7. Turn off <code>archive_mode</code> .....	324
14.4.8. Run <code>ANALYZE</code> Afterwards.....	325
14.4.9. Some Notes About <code>pg_dump</code> .....	325

<b>III. Server Administration .....</b>	<b>327</b>
15. Installation Instructions .....	329
15.1. Short Version .....	329
15.2. Requirements .....	329
15.3. Getting The Source .....	331
15.4. Upgrading .....	331
15.5. Installation Procedure .....	332
15.6. Post-Installation Setup .....	341
15.6.1. Shared Libraries .....	341
15.6.2. Environment Variables .....	342
15.7. Supported Platforms .....	342
16. Installation on Windows .....	344
16.1. Building with Visual C++ 2005 .....	344
16.1.1. Requirements .....	344
16.1.2. Building .....	345
16.1.3. Cleaning and installing .....	346
16.1.4. Running the regression tests .....	346
16.1.5. Building the documentation .....	347
16.2. Building libpq with Visual C++ or Borland C++ .....	348
16.2.1. Generated files .....	348
17. Operating System Environment .....	350
17.1. The PostgreSQL User Account .....	350
17.2. Creating a Database Cluster .....	350
17.2.1. Network File Systems .....	351
17.3. Starting the Database Server .....	351
17.3.1. Server Start-up Failures .....	353
17.3.2. Client Connection Problems .....	354
17.4. Managing Kernel Resources .....	354
17.4.1. Shared Memory and Semaphores .....	354
17.4.2. Resource Limits .....	360
17.4.3. Linux Memory Overcommit .....	361
17.5. Shutting Down the Server .....	362
17.6. Preventing Server Spoofing .....	363
17.7. Encryption Options .....	363
17.8. Secure TCP/IP Connections with SSL .....	364
17.8.1. Creating a Self-Signed Certificate .....	366
17.9. Secure TCP/IP Connections with SSH Tunnels .....	366
18. Server Configuration .....	368
18.1. Setting Parameters .....	368
18.2. File Locations .....	369
18.3. Connections and Authentication .....	370
18.3.1. Connection Settings .....	370
18.3.2. Security and Authentication .....	372
18.4. Resource Consumption .....	373
18.4.1. Memory .....	373
18.4.2. Free Space Map .....	375
18.4.3. Kernel Resource Usage .....	375
18.4.4. Cost-Based Vacuum Delay .....	376

18.4.5. Background Writer.....	377
18.5. Write Ahead Log.....	378
18.5.1. Settings.....	378
18.5.2. Checkpoints.....	380
18.5.3. Archiving .....	381
18.6. Query Planning.....	382
18.6.1. Planner Method Configuration.....	382
18.6.2. Planner Cost Constants .....	383
18.6.3. Genetic Query Optimizer .....	384
18.6.4. Other Planner Options.....	385
18.7. Error Reporting and Logging .....	386
18.7.1. Where To Log .....	386
18.7.2. When To Log .....	387
18.7.3. What To Log .....	389
18.7.4. Using CSV-Format Log Output .....	392
18.8. Run-Time Statistics .....	394
18.8.1. Query and Index Statistics Collector .....	394
18.8.2. Statistics Monitoring.....	394
18.9. Automatic Vacuuming.....	394
18.10. Client Connection Defaults .....	396
18.10.1. Statement Behavior .....	396
18.10.2. Locale and Formatting .....	399
18.10.3. Other Defaults .....	400
18.11. Lock Management .....	401
18.12. Version and Platform Compatibility.....	402
18.12.1. Previous PostgreSQL Versions .....	402
18.12.2. Platform and Client Compatibility.....	404
18.13. Preset Options.....	404
18.14. Customized Options .....	405
18.15. Developer Options .....	406
18.16. Short Options .....	407
19. Database Roles and Privileges .....	409
19.1. Database Roles .....	409
19.2. Role Attributes.....	410
19.3. Privileges .....	411
19.4. Role Membership .....	412
19.5. Functions and Triggers .....	413
20. Managing Databases .....	415
20.1. Overview .....	415
20.2. Creating a Database .....	415
20.3. Template Databases .....	416
20.4. Database Configuration .....	417
20.5. Destroying a Database .....	418
20.6. Tablespaces .....	418
21. Client Authentication .....	421
21.1. The <code>pg_hba.conf</code> file .....	421
21.2. Authentication methods.....	426
21.2.1. Trust authentication.....	426

21.2.2. Password authentication.....	427
21.2.3. GSSAPI authentication .....	427
21.2.4. SSPI authentication .....	427
21.2.5. Kerberos authentication .....	427
21.2.6. Ident-based authentication .....	429
21.2.6.1. Ident Authentication over TCP/IP .....	429
21.2.6.2. Ident Authentication over Local Sockets .....	429
21.2.6.3. Ident Maps .....	429
21.2.7. LDAP authentication.....	430
21.2.8. PAM authentication.....	431
21.3. Authentication problems .....	431
22. Localization.....	433
22.1. Locale Support.....	433
22.1.1. Overview .....	433
22.1.2. Behavior .....	434
22.1.3. Problems .....	435
22.2. Character Set Support.....	435
22.2.1. Supported Character Sets .....	436
22.2.2. Setting the Character Set.....	438
22.2.3. Automatic Character Set Conversion Between Server and Client .....	439
22.2.4. Further Reading .....	441
23. Routine Database Maintenance Tasks.....	443
23.1. Routine Vacuuming .....	443
23.1.1. Recovering Disk Space .....	443
23.1.2. Updating Planner Statistics .....	444
23.1.3. Preventing Transaction ID Wraparound Failures.....	445
23.1.4. The Auto-Vacuum Daemon .....	447
23.2. Routine Reindexing .....	448
23.3. Log File Maintenance.....	449
24. Backup and Restore .....	451
24.1. SQL Dump.....	451
24.1.1. Restoring the dump .....	451
24.1.2. Using pg_dumpall.....	452
24.1.3. Handling large databases .....	453
24.2. File System Level Backup .....	454
24.3. Continuous Archiving and Point-In-Time Recovery (PITR) .....	455
24.3.1. Setting up WAL archiving.....	456
24.3.2. Making a Base Backup .....	458
24.3.3. Recovering using a Continuous Archive Backup .....	460
24.3.3.1. Recovery Settings.....	462
24.3.4. Timelines.....	463
24.3.5. Tips and Examples .....	463
24.3.5.1. Standalone hot backups .....	463
24.3.5.2. archive_command scripts .....	464
24.3.6. Caveats .....	464
24.4. Warm Standby Servers for High Availability .....	465
24.4.1. Planning .....	466
24.4.2. Implementation .....	467

# Preface

This book is the official documentation of PostgreSQL. It is being written by the PostgreSQL developers and other volunteers in parallel to the development of the PostgreSQL software. It describes all the functionality that the current version of PostgreSQL officially supports.

To make the large amount of information about PostgreSQL manageable, this book has been organized in several parts. Each part is targeted at a different class of users, or at users in different stages of their PostgreSQL experience:

- Part I is an informal introduction for new users.
- Part II documents the SQL query language environment, including data types and functions, as well as user-level performance tuning. Every PostgreSQL user should read this.
- Part III describes the installation and administration of the server. Everyone who runs a PostgreSQL server, be it for private use or for others, should read this part.
- Part IV describes the programming interfaces for PostgreSQL client programs.
- Part V contains information for advanced users about the extensibility capabilities of the server. Topics are, for instance, user-defined data types and functions.
- Part VI contains reference information about SQL commands, client and server programs. This part supports the other parts with structured information sorted by command or program.
- Part VII contains assorted information that might be of use to PostgreSQL developers.

## 1. What is PostgreSQL?

PostgreSQL is an object-relational database management system (ORDBMS) based on POSTGRES, Version 4.2<sup>1</sup>, developed at the University of California at Berkeley Computer Science Department. POSTGRES pioneered many concepts that only became available in some commercial database systems much later.

PostgreSQL is an open-source descendant of this original Berkeley code. It supports a large part of the SQL standard and offers many modern features:

- complex queries
- foreign keys
- triggers
- views
- transactional integrity
- multiversion concurrency control

Also, PostgreSQL can be extended by the user in many ways, for example by adding new

- data types

---

1. <http://s2k-ftp.CS.Berkeley.EDU:8000/postgres/postgres.html>

- functions
- operators
- aggregate functions
- index methods
- procedural languages

And because of the liberal license, PostgreSQL can be used, modified, and distributed by everyone free of charge for any purpose, be it private, commercial, or academic.

## 2. A Brief History of PostgreSQL

The object-relational database management system now known as PostgreSQL is derived from the POSTGRES package written at the University of California at Berkeley. With over a decade of development behind it, PostgreSQL is now the most advanced open-source database available anywhere.

### 2.1. The Berkeley POSTGRES Project

The POSTGRES project, led by Professor Michael Stonebraker, was sponsored by the Defense Advanced Research Projects Agency (DARPA), the Army Research Office (ARO), the National Science Foundation (NSF), and ESL, Inc. The implementation of POSTGRES began in 1986. The initial concepts for the system were presented in *The design of POSTGRES*, and the definition of the initial data model appeared in *The POSTGRES data model*. The design of the rule system at that time was described in *The design of the POSTGRES rules system*. The rationale and architecture of the storage manager were detailed in *The design of the POSTGRES storage system*.

POSTGRES has undergone several major releases since then. The first “demoware” system became operational in 1987 and was shown at the 1988 ACM-SIGMOD Conference. Version 1, described in *The implementation of POSTGRES*, was released to a few external users in June 1989. In response to a critique of the first rule system (*A commentary on the POSTGRES rules system*), the rule system was redesigned (*On Rules, Procedures, Caching and Views in Database Systems*), and Version 2 was released in June 1990 with the new rule system. Version 3 appeared in 1991 and added support for multiple storage managers, an improved query executor, and a rewritten rule system. For the most part, subsequent releases until Postgres95 (see below) focused on portability and reliability.

POSTGRES has been used to implement many different research and production applications. These include: a financial data analysis system, a jet engine performance monitoring package, an asteroid tracking database, a medical information database, and several geographic information systems. POSTGRES has also been used as an educational tool at several universities. Finally, Illustra Information Technologies (later merged into Informix<sup>2</sup>, which is now owned by IBM<sup>3</sup>) picked up the code and commercialized it. In late 1992, POSTGRES became the primary data manager for the Sequoia 2000 scientific computing project<sup>4</sup>.

The size of the external user community nearly doubled during 1993. It became increasingly obvious that maintenance of the prototype code and support was taking up large amounts of time that should have been

4. [http://meteor.ucs.d.edu/s2k/s2k\\_home.html](http://meteor.ucs.d.edu/s2k/s2k_home.html)

devoted to database research. In an effort to reduce this support burden, the Berkeley POSTGRES project officially ended with Version 4.2.

## 2.2. Postgres95

In 1994, Andrew Yu and Jolly Chen added a SQL language interpreter to POSTGRES. Under a new name, Postgres95 was subsequently released to the web to find its own way in the world as an open-source descendant of the original POSTGRES Berkeley code.

Postgres95 code was completely ANSI C and trimmed in size by 25%. Many internal changes improved performance and maintainability. Postgres95 release 1.0.x ran about 30-50% faster on the Wisconsin Benchmark compared to POSTGRES, Version 4.2. Apart from bug fixes, the following were the major enhancements:

- The query language PostQUEL was replaced with SQL (implemented in the server). Subqueries were not supported until PostgreSQL (see below), but they could be imitated in Postgres95 with user-defined SQL functions. Aggregate functions were re-implemented. Support for the `GROUP BY` query clause was also added.
- A new program (`psql`) was provided for interactive SQL queries, which used GNU Readline. This largely superseded the old monitor program.
- A new front-end library, `libpgtcl`, supported Tcl-based clients. A sample shell, `pgtclsh`, provided new Tcl commands to interface Tcl programs with the Postgres95 server.
- The large-object interface was overhauled. The inversion large objects were the only mechanism for storing large objects. (The inversion file system was removed.)
- The instance-level rule system was removed. Rules were still available as rewrite rules.
- A short tutorial introducing regular SQL features as well as those of Postgres95 was distributed with the source code
- GNU make (instead of BSD make) was used for the build. Also, Postgres95 could be compiled with an unpatched GCC (data alignment of doubles was fixed).

## 2.3. PostgreSQL

By 1996, it became clear that the name “Postgres95” would not stand the test of time. We chose a new name, PostgreSQL, to reflect the relationship between the original POSTGRES and the more recent versions with SQL capability. At the same time, we set the version numbering to start at 6.0, putting the numbers back into the sequence originally begun by the Berkeley POSTGRES project.

Many people continue to refer to PostgreSQL as “Postgres” (now rarely in all capital letters) because of tradition or because it is easier to pronounce. This usage is widely accepted as a nickname or alias.

The emphasis during development of Postgres95 was on identifying and understanding existing problems in the server code. With PostgreSQL, the emphasis has shifted to augmenting features and capabilities, although work continues in all areas.

Details about what has happened in PostgreSQL since then can be found in Appendix E.

### 3. Conventions

This book uses the following typographical conventions to mark certain portions of text: new terms, foreign phrases, and other important passages are emphasized in *italics*. Everything that represents input or output of the computer, in particular commands, program code, and screen output, is shown in a monospaced font (`example`). Within such passages, italics (*example*) indicate placeholders; you must insert an actual value instead of the placeholder. On occasion, parts of program code are emphasized in bold face (**example**), if they have been added or changed since the preceding example.

The following conventions are used in the synopsis of a command: brackets ([ and ]) indicate optional parts. (In the synopsis of a Tcl command, question marks (?) are used instead, as is usual in Tcl.) Braces ({ and }) and vertical lines (|) indicate that you must choose one alternative. Dots ( . . . ) mean that the preceding element can be repeated.

Where it enhances the clarity, SQL commands are preceded by the prompt =>, and shell commands are preceded by the prompt \$. Normally, prompts are not shown, though.

An *administrator* is generally a person who is in charge of installing and running the server. A *user* could be anyone who is using, or wants to use, any part of the PostgreSQL system. These terms should not be interpreted too narrowly; this book does not have fixed presumptions about system administration procedures.

### 4. Further Information

Besides the documentation, that is, this book, there are other resources about PostgreSQL:

#### FAQs

The FAQ list contains continuously updated answers to frequently asked questions.

#### Web Site

The PostgreSQL web site<sup>5</sup> carries details on the latest release and other information to make your work or play with PostgreSQL more productive.

#### Mailing Lists

The mailing lists are a good place to have your questions answered, to share experiences with other users, and to contact the developers. Consult the PostgreSQL web site for details.

#### Yourself!

PostgreSQL is an open-source project. As such, it depends on the user community for ongoing support. As you begin to use PostgreSQL, you will rely on others for help, either through the documentation or through the mailing lists. Consider contributing your knowledge back. Read the mailing

---

5. <http://www.postgresql.org>

lists and answer questions. If you learn something which is not in the documentation, write it up and contribute it. If you add features to the code, contribute them.

## 5. Bug Reporting Guidelines

When you find a bug in PostgreSQL we want to hear about it. Your bug reports play an important part in making PostgreSQL more reliable because even the utmost care cannot guarantee that every part of PostgreSQL will work on every platform under every circumstance.

The following suggestions are intended to assist you in forming bug reports that can be handled in an effective fashion. No one is required to follow them but doing so tends to be to everyone's advantage.

We cannot promise to fix every bug right away. If the bug is obvious, critical, or affects a lot of users, chances are good that someone will look into it. It could also happen that we tell you to update to a newer version to see if the bug happens there. Or we might decide that the bug cannot be fixed before some major rewrite we might be planning is done. Or perhaps it is simply too hard and there are more important things on the agenda. If you need help immediately, consider obtaining a commercial support contract.

### 5.1. Identifying Bugs

Before you report a bug, please read and re-read the documentation to verify that you can really do whatever it is you are trying. If it is not clear from the documentation whether you can do something or not, please report that too; it is a bug in the documentation. If it turns out that a program does something different from what the documentation says, that is a bug. That might include, but is not limited to, the following circumstances:

- A program terminates with a fatal signal or an operating system error message that would point to a problem in the program. (A counterexample might be a “disk full” message, since you have to fix that yourself.)
- A program produces the wrong output for any given input.
- A program refuses to accept valid input (as defined in the documentation).
- A program accepts invalid input without a notice or error message. But keep in mind that your idea of invalid input might be our idea of an extension or compatibility with traditional practice.
- PostgreSQL fails to compile, build, or install according to the instructions on supported platforms.

Here “program” refers to any executable, not only the backend server.

Being slow or resource-hogging is not necessarily a bug. Read the documentation or ask on one of the mailing lists for help in tuning your applications. Failing to comply to the SQL standard is not necessarily a bug either, unless compliance for the specific feature is explicitly claimed.

Before you continue, check on the TODO list and in the FAQ to see if your bug is already known. If you cannot decode the information on the TODO list, report your problem. The least we can do is make the TODO list clearer.

## 5.2. What to report

The most important thing to remember about bug reporting is to state all the facts and only facts. Do not speculate what you think went wrong, what “it seemed to do”, or which part of the program has a fault. If you are not familiar with the implementation you would probably guess wrong and not help us a bit. And even if you are, educated explanations are a great supplement to but no substitute for facts. If we are going to fix the bug we still have to see it happen for ourselves first. Reporting the bare facts is relatively straightforward (you can probably copy and paste them from the screen) but all too often important details are left out because someone thought it does not matter or the report would be understood anyway.

The following items should be contained in every bug report:

- The exact sequence of steps *from program start-up* necessary to reproduce the problem. This should be self-contained; it is not enough to send in a bare `SELECT` statement without the preceding `CREATE TABLE` and `INSERT` statements, if the output should depend on the data in the tables. We do not have the time to reverse-engineer your database schema, and if we are supposed to make up our own data we would probably miss the problem.

The best format for a test case for SQL-related problems is a file that can be run through the `psql` frontend that shows the problem. (Be sure to not have anything in your `~/.psqlrc` start-up file.) An easy start at this file is to use `pg_dump` to dump out the table declarations and data needed to set the scene, then add the problem query. You are encouraged to minimize the size of your example, but this is not absolutely necessary. If the bug is reproducible, we will find it either way.

If your application uses some other client interface, such as PHP, then please try to isolate the offending queries. We will probably not set up a web server to reproduce your problem. In any case remember to provide the exact input files; do not guess that the problem happens for “large files” or “midsize databases”, etc. since this information is too inexact to be of use.

- The output you got. Please do not say that it “didn’t work” or “crashed”. If there is an error message, show it, even if you do not understand it. If the program terminates with an operating system error, say which. If nothing at all happens, say so. Even if the result of your test case is a program crash or otherwise obvious it might not happen on our platform. The easiest thing is to copy the output from the terminal, if possible.

**Note:** If you are reporting an error message, please obtain the most verbose form of the message. In `psql`, say `\set VERBOSITY verbose` beforehand. If you are extracting the message from the server log, set the run-time parameter `log_error_verbosity` to `verbose` so that all details are logged.

**Note:** In case of fatal errors, the error message reported by the client might not contain all the information available. Please also look at the log output of the database server. If you do not keep your server’s log output, this would be a good time to start doing so.

- The output you expected is very important to state. If you just write “This command gives me that output.” or “This is not what I expected.”, we might run it ourselves, scan the output, and think it looks OK and is exactly what we expected. We should not have to spend the time to decode the exact semantics behind your commands. Especially refrain from merely saying that “This is not what SQL

says/Oracle does.” Digging out the correct behavior from SQL is not a fun undertaking, nor do we all know how all the other relational databases out there behave. (If your problem is a program crash, you can obviously omit this item.)

- Any command line options and other start-up options, including any relevant environment variables or configuration files that you changed from the default. Again, please provide exact information. If you are using a prepackaged distribution that starts the database server at boot time, you should try to find out how that is done.
- Anything you did at all differently from the installation instructions.
- The PostgreSQL version. You can run the command `SELECT version();` to find out the version of the server you are connected to. Most executable programs also support a `--version` option; at least `postgres --version` and `psql --version` should work. If the function or the options do not exist then your version is more than old enough to warrant an upgrade. If you run a prepackaged version, such as RPMs, say so, including any subversion the package might have. If you are talking about a CVS snapshot, mention that, including its date and time.

If your version is older than 8.3.1 we will almost certainly tell you to upgrade. There are many bug fixes and improvements in each new release, so it is quite possible that a bug you have encountered in an older release of PostgreSQL has already been fixed. We can only provide limited support for sites using older releases of PostgreSQL; if you require more than we can provide, consider acquiring a commercial support contract.

- Platform information. This includes the kernel name and version, C library, processor, memory information, and so on. In most cases it is sufficient to report the vendor and version, but do not assume everyone knows what exactly “Debian” contains or that everyone runs on Pentiums. If you have installation problems then information about the toolchain on your machine (compiler, make, and so on) is also necessary.

Do not be afraid if your bug report becomes rather lengthy. That is a fact of life. It is better to report everything the first time than us having to squeeze the facts out of you. On the other hand, if your input files are huge, it is fair to ask first whether somebody is interested in looking into it. Here is an article<sup>6</sup> that outlines some more tips on reporting bugs.

Do not spend all your time to figure out which changes in the input make the problem go away. This will probably not help solving it. If it turns out that the bug cannot be fixed right away, you will still have time to find and share your work-around. Also, once again, do not waste your time guessing why the bug exists. We will find that out soon enough.

When writing a bug report, please avoid confusing terminology. The software package in total is called “PostgreSQL”, sometimes “Postgres” for short. If you are specifically talking about the backend server, mention that, do not just say “PostgreSQL crashes”. A crash of a single backend server process is quite different from crash of the parent “postgres” process; please don’t say “the server crashed” when you mean a single backend process went down, nor vice versa. Also, client programs such as the interactive frontend “psql” are completely separate from the backend. Please try to be specific about whether the problem is on the client or server side.

---

6. <http://www.chiark.greenend.org.uk/~sgtatham/bugs.html>

## 5.3. Where to report bugs

In general, send bug reports to the bug report mailing list at `<pgsql-bugs@postgresql.org>`. You are requested to use a descriptive subject for your email message, perhaps parts of the error message.

Another method is to fill in the bug report web-form available at the project's web site<sup>7</sup>. Entering a bug report this way causes it to be mailed to the `<pgsql-bugs@postgresql.org>` mailing list.

If your bug report has security implications and you'd prefer that it not become immediately visible in public archives, don't send it to `pgsql-bugs`. Security issues can be reported privately to `<security@postgresql.org>`.

Do not send bug reports to any of the user mailing lists, such as `<pgsql-sql@postgresql.org>` or `<pgsql-general@postgresql.org>`. These mailing lists are for answering user questions, and their subscribers normally do not wish to receive bug reports. More importantly, they are unlikely to fix them.

Also, please do *not* send reports to the developers' mailing list `<pgsql-hackers@postgresql.org>`. This list is for discussing the development of PostgreSQL, and it would be nice if we could keep the bug reports separate. We might choose to take up a discussion about your bug report on `pgsql-hackers`, if the problem needs more review.

If you have a problem with the documentation, the best place to report it is the documentation mailing list `<pgsql-docs@postgresql.org>`. Please be specific about what part of the documentation you are unhappy with.

If your bug is a portability problem on a non-supported platform, send mail to `<pgsql-ports@postgresql.org>`, so we (and you) can work on porting PostgreSQL to your platform.

**Note:** Due to the unfortunate amount of spam going around, all of the above email addresses are closed mailing lists. That is, you need to be subscribed to a list to be allowed to post on it. (You need not be subscribed to use the bug-report web form, however.) If you would like to send mail but do not want to receive list traffic, you can subscribe and set your subscription option to `nomail`. For more information send mail to `<majordomo@postgresql.org>` with the single word `help` in the body of the message.

---

7. <http://www.postgresql.org/>

# I. Tutorial

Welcome to the PostgreSQL Tutorial. The following few chapters are intended to give a simple introduction to PostgreSQL, relational database concepts, and the SQL language to those who are new to any one of these aspects. We only assume some general knowledge about how to use computers. No particular Unix or programming experience is required. This part is mainly intended to give you some hands-on experience with important aspects of the PostgreSQL system. It makes no attempt to be a complete or thorough treatment of the topics it covers.

After you have worked through this tutorial you might want to move on to reading Part II to gain a more formal knowledge of the SQL language, or Part IV for information about developing applications for PostgreSQL. Those who set up and manage their own server should also read Part III.

# Chapter 1. Getting Started

## 1.1. Installation

Before you can use PostgreSQL you need to install it, of course. It is possible that PostgreSQL is already installed at your site, either because it was included in your operating system distribution or because the system administrator already installed it. If that is the case, you should obtain information from the operating system documentation or your system administrator about how to access PostgreSQL.

If you are not sure whether PostgreSQL is already available or whether you can use it for your experimentation then you can install it yourself. Doing so is not hard and it can be a good exercise. PostgreSQL can be installed by any unprivileged user; no superuser (root) access is required.

If you are installing PostgreSQL yourself, then refer to Chapter 15 for instructions on installation, and return to this guide when the installation is complete. Be sure to follow closely the section about setting up the appropriate environment variables.

If your site administrator has not set things up in the default way, you might have some more work to do. For example, if the database server machine is a remote machine, you will need to set the `PGHOST` environment variable to the name of the database server machine. The environment variable `PGPORT` might also have to be set. The bottom line is this: if you try to start an application program and it complains that it cannot connect to the database, you should consult your site administrator or, if that is you, the documentation to make sure that your environment is properly set up. If you did not understand the preceding paragraph then read the next section.

## 1.2. Architectural Fundamentals

Before we proceed, you should understand the basic PostgreSQL system architecture. Understanding how the parts of PostgreSQL interact will make this chapter somewhat clearer.

In database jargon, PostgreSQL uses a client/server model. A PostgreSQL session consists of the following cooperating processes (programs):

- A server process, which manages the database files, accepts connections to the database from client applications, and performs actions on the database on behalf of the clients. The database server program is called `postgres`.
- The user's client (frontend) application that wants to perform database operations. Client applications can be very diverse in nature: a client could be a text-oriented tool, a graphical application, a web server that accesses the database to display web pages, or a specialized database maintenance tool. Some client applications are supplied with the PostgreSQL distribution; most are developed by users.

As is typical of client/server applications, the client and the server can be on different hosts. In that case they communicate over a TCP/IP network connection. You should keep this in mind, because the files that can be accessed on a client machine might not be accessible (or might only be accessible using a different file name) on the database server machine.

The PostgreSQL server can handle multiple concurrent connections from clients. For that purpose it starts (“forks”) a new process for each connection. From that point on, the client and the new server process communicate without intervention by the original `postgres` process. Thus, the master server process is always running, waiting for client connections, whereas client and associated server processes come and go. (All of this is of course invisible to the user. We only mention it here for completeness.)

## 1.3. Creating a Database

The first test to see whether you can access the database server is to try to create a database. A running PostgreSQL server can manage many databases. Typically, a separate database is used for each project or for each user.

Possibly, your site administrator has already created a database for your use. He should have told you what the name of your database is. In that case you can omit this step and skip ahead to the next section.

To create a new database, in this example named `mydb`, you use the following command:

```
$ createdb mydb
```

If this produces no response then this step was successful and you can skip over the remainder of this section.

If you see a message similar to

```
createdb: command not found
```

then PostgreSQL was not installed properly. Either it was not installed at all or the search path was not set correctly. Try calling the command with an absolute path instead:

```
$ /usr/local/pgsql/bin/createdb mydb
```

The path at your site might be different. Contact your site administrator or check back in the installation instructions to correct the situation.

Another response could be this:

```
createdb: could not connect to database postgres: could not connect to server: No such file
Is the server running locally and accepting
connections on Unix domain socket "/tmp/.s.PGSQL.5432"?
```

This means that the server was not started, or it was not started where `createdb` expected it. Again, check the installation instructions or consult the administrator.

Another response could be this:

```
createdb: could not connect to database postgres: FATAL:  role "joe" does not exist
```

where your own login name is mentioned. This will happen if the administrator has not created a PostgreSQL user account for you. (PostgreSQL user accounts are distinct from operating system user accounts.) If you are the administrator, see Chapter 19 for help creating accounts. You will need to become the operating system user under which PostgreSQL was installed (usually `postgres`) to create the first user account. It could also be that you were assigned a PostgreSQL user name that is different from your

operating system user name; in that case you need to use the `-U` switch or set the `PGUSER` environment variable to specify your PostgreSQL user name.

If you have a user account but it does not have the privileges required to create a database, you will see the following:

```
createdb: database creation failed: ERROR: permission denied to create database
```

Not every user has authorization to create new databases. If PostgreSQL refuses to create databases for you then the site administrator needs to grant you permission to create databases. Consult your site administrator if this occurs. If you installed PostgreSQL yourself then you should log in for the purposes of this tutorial under the user account that you started the server as.<sup>1</sup>

You can also create databases with other names. PostgreSQL allows you to create any number of databases at a given site. Database names must have an alphabetic first character and are limited to 63 characters in length. A convenient choice is to create a database with the same name as your current user name. Many tools assume that database name as the default, so it can save you some typing. To create that database, simply type

```
$ createdb
```

If you do not want to use your database anymore you can remove it. For example, if you are the owner (creator) of the database `mydb`, you can destroy it using the following command:

```
$ dropdb mydb
```

(For this command, the database name does not default to the user account name. You always need to specify it.) This action physically removes all files associated with the database and cannot be undone, so this should only be done with a great deal of forethought.

More about `createdb` and `dropdb` can be found in `createdb` and `dropdb` respectively.

## 1.4. Accessing a Database

Once you have created a database, you can access it by:

- Running the PostgreSQL interactive terminal program, called *psql*, which allows you to interactively enter, edit, and execute SQL commands.
- Using an existing graphical frontend tool like pgAdmin or an office suite with ODBC support to create and manipulate a database. These possibilities are not covered in this tutorial.
- Writing a custom application, using one of the several available language bindings. These possibilities are discussed further in Part IV.

---

1. As an explanation for why this works: PostgreSQL user names are separate from operating system user accounts. When you connect to a database, you can choose what PostgreSQL user name to connect as; if you don't, it will default to the same name as your current operating system account. As it happens, there will always be a PostgreSQL user account that has the same name as the operating system user that started the server, and it also happens that that user always has permission to create databases. Instead of logging in as that user you can also specify the `-U` option everywhere to select a PostgreSQL user name to connect as.

You probably want to start up `psql`, to try out the examples in this tutorial. It can be activated for the `mydb` database by typing the command:

```
$ psql mydb
```

If you leave off the database name then it will default to your user account name. You already discovered this scheme in the previous section.

In `psql`, you will be greeted with the following message:

```
Welcome to psql 8.3.1, the PostgreSQL interactive terminal.
```

```
Type:  \copyright for distribution terms
        \h for help with SQL commands
        \? for help with psql commands
        \g or terminate with semicolon to execute query
        \q to quit
```

```
mydb=>
```

The last line could also be

```
mydb=#
```

That would mean you are a database superuser, which is most likely the case if you installed PostgreSQL yourself. Being a superuser means that you are not subject to access controls. For the purposes of this tutorial that is not of importance.

If you encounter problems starting `psql` then go back to the previous section. The diagnostics of `createdb` and `psql` are similar, and if the former worked the latter should work as well.

The last line printed out by `psql` is the prompt, and it indicates that `psql` is listening to you and that you can type SQL queries into a work space maintained by `psql`. Try out these commands:

```
mydb=> SELECT version();
               version
-----
PostgreSQL 8.3.1 on i586-pc-linux-gnu, compiled by GCC 2.96

```

The `psql` program has a number of internal commands that are not SQL commands. They begin with the backslash character, “\”. Some of these commands were listed in the welcome message. For example, you can get help on the syntax of various PostgreSQL SQL commands by typing:

```
mydb=> \h
```

To get out of `psql`, type

```
mydb=> \q
```

and `psql` will quit and return you to your command shell. (For more internal commands, type `\?` at the `psql` prompt.) The full capabilities of `psql` are documented in `psql`. If PostgreSQL is installed correctly you can also type `man psql` at the operating system shell prompt to see the documentation. In this tutorial we will not use these features explicitly, but you can use them yourself when you see fit.

# Chapter 2. The SQL Language

## 2.1. Introduction

This chapter provides an overview of how to use SQL to perform simple operations. This tutorial is only intended to give you an introduction and is in no way a complete tutorial on SQL. Numerous books have been written on SQL, including *Understanding the New SQL* and *A Guide to the SQL Standard*. You should be aware that some PostgreSQL language features are extensions to the standard.

In the examples that follow, we assume that you have created a database named `mydb`, as described in the previous chapter, and have been able to start `psql`.

Examples in this manual can also be found in the PostgreSQL source distribution in the directory `src/tutorial/`. To use those files, first change to that directory and run `make`:

```
$ cd ../src/tutorial
$ make
```

This creates the scripts and compiles the C files containing user-defined functions and types. (If you installed a pre-packaged version of PostgreSQL rather than building from source, look for a directory named `tutorial` within the PostgreSQL documentation. The “make” part should already have been done for you.) Then, to start the tutorial, do the following:

```
$ cd ../tutorial
$ psql -s mydb
...
```

```
mydb=> \i basics.sql
```

The `\i` command reads in commands from the specified file. The `-s` option puts you in single step mode which pauses before sending each statement to the server. The commands used in this section are in the file `basics.sql`.

## 2.2. Concepts

PostgreSQL is a *relational database management system* (RDBMS). That means it is a system for managing data stored in *relations*. Relation is essentially a mathematical term for *table*. The notion of storing data in tables is so commonplace today that it might seem inherently obvious, but there are a number of other ways of organizing databases. Files and directories on Unix-like operating systems form an example of a hierarchical database. A more modern development is the object-oriented database.

Each table is a named collection of *rows*. Each row of a given table has the same set of named *columns*, and each column is of a specific data type. Whereas columns have a fixed order in each row, it is important to remember that SQL does not guarantee the order of the rows within the table in any way (although they can be explicitly sorted for display).

Tables are grouped into databases, and a collection of databases managed by a single PostgreSQL server instance constitutes a database *cluster*.

## 2.3. Creating a New Table

You can create a new table by specifying the table name, along with all column names and their types:

```
CREATE TABLE weather (
    city          varchar(80),
    temp_lo       int,          -- low temperature
    temp_hi       int,          -- high temperature
    prcp          real,         -- precipitation
    date          date
);
```

You can enter this into `psql` with the line breaks. `psql` will recognize that the command is not terminated until the semicolon.

White space (i.e., spaces, tabs, and newlines) can be used freely in SQL commands. That means you can type the command aligned differently than above, or even all on one line. Two dashes (“--”) introduce comments. Whatever follows them is ignored up to the end of the line. SQL is case insensitive about key words and identifiers, except when identifiers are double-quoted to preserve the case (not done above).

`varchar(80)` specifies a data type that can store arbitrary character strings up to 80 characters in length. `int` is the normal integer type. `real` is a type for storing single precision floating-point numbers. `date` should be self-explanatory. (Yes, the column of type `date` is also named `date`. This might be convenient or confusing — you choose.)

PostgreSQL supports the standard SQL types `int`, `smallint`, `real`, `double precision`, `char(N)`, `varchar(N)`, `date`, `time`, `timestamp`, and `interval`, as well as other types of general utility and a rich set of geometric types. PostgreSQL can be customized with an arbitrary number of user-defined data types. Consequently, type names are not syntactical key words, except where required to support special cases in the SQL standard.

The second example will store cities and their associated geographical location:

```
CREATE TABLE cities (
    name          varchar(80),
    location      point
);
```

The `point` type is an example of a PostgreSQL-specific data type.

Finally, it should be mentioned that if you don’t need a table any longer or want to recreate it differently you can remove it using the following command:

```
DROP TABLE tablename;
```

## 2.4. Populating a Table With Rows

The `INSERT` statement is used to populate a table with rows:

```
INSERT INTO weather VALUES ('San Francisco', 46, 50, 0.25, '1994-11-27');
```

Note that all data types use rather obvious input formats. Constants that are not simple numeric values usually must be surrounded by single quotes (`'`), as in the example. The `date` type is actually quite flexible in what it accepts, but for this tutorial we will stick to the unambiguous format shown here.

The `point` type requires a coordinate pair as input, as shown here:

```
INSERT INTO cities VALUES ('San Francisco', '(-194.0, 53.0)');
```

The syntax used so far requires you to remember the order of the columns. An alternative syntax allows you to list the columns explicitly:

```
INSERT INTO weather (city, temp_lo, temp_hi, prcp, date)
VALUES ('San Francisco', 43, 57, 0.0, '1994-11-29');
```

You can list the columns in a different order if you wish or even omit some columns, e.g., if the precipitation is unknown:

```
INSERT INTO weather (date, city, temp_hi, temp_lo)
VALUES ('1994-11-29', 'Hayward', 54, 37);
```

Many developers consider explicitly listing the columns better style than relying on the order implicitly.

Please enter all the commands shown above so you have some data to work with in the following sections.

You could also have used `COPY` to load large amounts of data from flat-text files. This is usually faster because the `COPY` command is optimized for this application while allowing less flexibility than `INSERT`. An example would be:

```
COPY weather FROM '/home/user/weather.txt';
```

where the file name for the source file must be available to the backend server machine, not the client, since the backend server reads the file directly. You can read more about the `COPY` command in *COPY*.

## 2.5. Querying a Table

To retrieve data from a table, the table is *queried*. An SQL `SELECT` statement is used to do this. The statement is divided into a select list (the part that lists the columns to be returned), a table list (the part that lists the tables from which to retrieve the data), and an optional qualification (the part that specifies any restrictions). For example, to retrieve all the rows of table `weather`, type:

```
SELECT * FROM weather;
```

Here `*` is a shorthand for “all columns”.<sup>1</sup> So the same result would be had with:

```
SELECT city, temp_lo, temp_hi, prcp, date FROM weather;
```

The output should be:

---

1. While `SELECT *` is useful for off-the-cuff queries, it is widely considered bad style in production code, since adding a column to the table would change the results.

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	43	57	0	1994-11-29
Hayward	37	54		1994-11-29

(3 rows)

You can write expressions, not just simple column references, in the select list. For example, you can do:

```
SELECT city, (temp_hi+temp_lo)/2 AS temp_avg, date FROM weather;
```

This should give:

city	temp_avg	date
San Francisco	48	1994-11-27
San Francisco	50	1994-11-29
Hayward	45	1994-11-29

(3 rows)

Notice how the `AS` clause is used to relabel the output column. (The `AS` clause is optional.)

A query can be “qualified” by adding a `WHERE` clause that specifies which rows are wanted. The `WHERE` clause contains a Boolean (truth value) expression, and only rows for which the Boolean expression is true are returned. The usual Boolean operators (`AND`, `OR`, and `NOT`) are allowed in the qualification. For example, the following retrieves the weather of San Francisco on rainy days:

```
SELECT * FROM weather
WHERE city = 'San Francisco' AND prcp > 0.0;
```

Result:

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27

(1 row)

You can request that the results of a query be returned in sorted order:

```
SELECT * FROM weather
ORDER BY city;
```

city	temp_lo	temp_hi	prcp	date
Hayward	37	54		1994-11-29
San Francisco	43	57	0	1994-11-29
San Francisco	46	50	0.25	1994-11-27

In this example, the sort order isn’t fully specified, and so you might get the San Francisco rows in either order. But you’d always get the results shown above if you do:

```
SELECT * FROM weather
      ORDER BY city, temp_lo;
```

You can request that duplicate rows be removed from the result of a query:

```
SELECT DISTINCT city
      FROM weather;
```

```
      city
-----
 Hayward
San Francisco
(2 rows)
```

Here again, the result row ordering might vary. You can ensure consistent results by using `DISTINCT` and `ORDER BY` together:<sup>2</sup>

```
SELECT DISTINCT city
      FROM weather
      ORDER BY city;
```

## 2.6. Joins Between Tables

Thus far, our queries have only accessed one table at a time. Queries can access multiple tables at once, or access the same table in such a way that multiple rows of the table are being processed at the same time. A query that accesses multiple rows of the same or different tables at one time is called a *join* query. As an example, say you wish to list all the weather records together with the location of the associated city. To do that, we need to compare the city column of each row of the weather table with the name column of all rows in the cities table, and select the pairs of rows where these values match.

**Note:** This is only a conceptual model. The join is usually performed in a more efficient manner than actually comparing each possible pair of rows, but this is invisible to the user.

This would be accomplished by the following query:

```
SELECT *
      FROM weather, cities
      WHERE city = name;
```

```
      city      | temp_lo | temp_hi | prcp | date      | name      | location
-----+-----+-----+-----+-----+-----+-----
San Francisco |      46 |      50 | 0.25 | 1994-11-27 | San Francisco | (-194,53)
San Francisco |      43 |      57 | 0    | 1994-11-29 | San Francisco | (-194,53)
(2 rows)
```

2. In some database systems, including older versions of PostgreSQL, the implementation of `DISTINCT` automatically orders the rows and so `ORDER BY` is unnecessary. But this is not required by the SQL standard, and current PostgreSQL doesn't guarantee that `DISTINCT` causes the rows to be ordered.

Observe two things about the result set:

- There is no result row for the city of Hayward. This is because there is no matching entry in the `cities` table for Hayward, so the join ignores the unmatched rows in the `weather` table. We will see shortly how this can be fixed.
- There are two columns containing the city name. This is correct because the lists of columns of the `weather` and the `cities` table are concatenated. In practice this is undesirable, though, so you will probably want to list the output columns explicitly rather than using `*`:

```
SELECT city, temp_lo, temp_hi, prcp, date, location
FROM weather, cities
WHERE city = name;
```

**Exercise:** Attempt to find out the semantics of this query when the `WHERE` clause is omitted.

Since the columns all had different names, the parser automatically found out which table they belong to. If there were duplicate column names in the two tables you’d need to *qualify* the column names to show which one you meant, as in:

```
SELECT weather.city, weather.temp_lo, weather.temp_hi,
       weather.prcp, weather.date, cities.location
FROM weather, cities
WHERE cities.name = weather.city;
```

It is widely considered good style to qualify all column names in a join query, so that the query won’t fail if a duplicate column name is later added to one of the tables.

Join queries of the kind seen thus far can also be written in this alternative form:

```
SELECT *
FROM weather INNER JOIN cities ON (weather.city = cities.name);
```

This syntax is not as commonly used as the one above, but we show it here to help you understand the following topics.

Now we will figure out how we can get the Hayward records back in. What we want the query to do is to scan the `weather` table and for each row to find the matching `cities` row(s). If no matching row is found we want some “empty values” to be substituted for the `cities` table’s columns. This kind of query is called an *outer join*. (The joins we have seen so far are inner joins.) The command looks like this:

```
SELECT *
FROM weather LEFT OUTER JOIN cities ON (weather.city = cities.name);
```

city	temp_lo	temp_hi	prcp	date	name	location
Hayward	37	54		1994-11-29		
San Francisco	46	50	0.25	1994-11-27	San Francisco	(-194, 53)
San Francisco	43	57	0	1994-11-29	San Francisco	(-194, 53)

(3 rows)

This query is called a *left outer join* because the table mentioned on the left of the join operator will have each of its rows in the output at least once, whereas the table on the right will only have those rows output that match some row of the left table. When outputting a left-table row for which there is no right-table match, empty (null) values are substituted for the right-table columns.

**Exercise:** There are also right outer joins and full outer joins. Try to find out what those do.

We can also join a table against itself. This is called a *self join*. As an example, suppose we wish to find all the weather records that are in the temperature range of other weather records. So we need to compare the `temp_lo` and `temp_hi` columns of each weather row to the `temp_lo` and `temp_hi` columns of all other weather rows. We can do this with the following query:

```
SELECT W1.city, W1.temp_lo AS low, W1.temp_hi AS high,
       W2.city, W2.temp_lo AS low, W2.temp_hi AS high
FROM   weather W1, weather W2
WHERE  W1.temp_lo < W2.temp_lo
AND    W1.temp_hi > W2.temp_hi;
```

city	low	high	city	low	high
San Francisco	43	57	San Francisco	46	50
Hayward	37	54	San Francisco	46	50

(2 rows)

Here we have relabeled the weather table as `W1` and `W2` to be able to distinguish the left and right side of the join. You can also use these kinds of aliases in other queries to save some typing, e.g.:

```
SELECT *
FROM   weather w, cities c
WHERE  w.city = c.name;
```

You will encounter this style of abbreviating quite frequently.

## 2.7. Aggregate Functions

Like most other relational database products, PostgreSQL supports aggregate functions. An aggregate function computes a single result from multiple input rows. For example, there are aggregates to compute the `count`, `sum`, `avg` (average), `max` (maximum) and `min` (minimum) over a set of rows.

As an example, we can find the highest low-temperature reading anywhere with:

```
SELECT max(temp_lo) FROM weather;
```

```
max
-----
46
(1 row)
```

If we wanted to know what city (or cities) that reading occurred in, we might try:

```
SELECT city FROM weather WHERE temp_lo = max(temp_lo);      WRONG
```

but this will not work since the aggregate `max` cannot be used in the `WHERE` clause. (This restriction exists because the `WHERE` clause determines which rows will be included in the aggregate calculation; so obviously it has to be evaluated before aggregate functions are computed.) However, as is often the case the query can be restated to accomplish the desired result, here by using a *subquery*:

```
SELECT city FROM weather
   WHERE temp_lo = (SELECT max(temp_lo) FROM weather);

   city
-----
San Francisco
(1 row)
```

This is OK because the subquery is an independent computation that computes its own aggregate separately from what is happening in the outer query.

Aggregates are also very useful in combination with `GROUP BY` clauses. For example, we can get the maximum low temperature observed in each city with:

```
SELECT city, max(temp_lo)
   FROM weather
   GROUP BY city;

   city      | max
-----+-----
Hayward      |   37
San Francisco |   46
(2 rows)
```

which gives us one output row per city. Each aggregate result is computed over the table rows matching that city. We can filter these grouped rows using `HAVING`:

```
SELECT city, max(temp_lo)
   FROM weather
   GROUP BY city
   HAVING max(temp_lo) < 40;

   city      | max
-----+-----
Hayward      |   37
(1 row)
```

which gives us the same results for only the cities that have all `temp_lo` values below 40. Finally, if we only care about cities whose names begin with “S”, we might do:

```
SELECT city, max(temp_lo)
   FROM weather
   WHERE city LIKE 'S%'❶
   GROUP BY city
   HAVING max(temp_lo) < 40;
```

- ❶ The `LIKE` operator does pattern matching and is explained in Section 9.7.

It is important to understand the interaction between aggregates and SQL's `WHERE` and `HAVING` clauses. The fundamental difference between `WHERE` and `HAVING` is this: `WHERE` selects input rows before groups and aggregates are computed (thus, it controls which rows go into the aggregate computation), whereas `HAVING` selects group rows after groups and aggregates are computed. Thus, the `WHERE` clause must not contain aggregate functions; it makes no sense to try to use an aggregate to determine which rows will be inputs to the aggregates. On the other hand, the `HAVING` clause always contains aggregate functions. (Strictly speaking, you are allowed to write a `HAVING` clause that doesn't use aggregates, but it's seldom useful. The same condition could be used more efficiently at the `WHERE` stage.)

In the previous example, we can apply the city name restriction in `WHERE`, since it needs no aggregate. This is more efficient than adding the restriction to `HAVING`, because we avoid doing the grouping and aggregate calculations for all rows that fail the `WHERE` check.

## 2.8. Updates

You can update existing rows using the `UPDATE` command. Suppose you discover the temperature readings are all off by 2 degrees after November 28. You can correct the data as follows:

```
UPDATE weather
  SET temp_hi = temp_hi - 2, temp_lo = temp_lo - 2
  WHERE date > '1994-11-28';
```

Look at the new state of the data:

```
SELECT * FROM weather;
```

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	41	55	0	1994-11-29
Hayward	35	52		1994-11-29

(3 rows)

## 2.9. Deletions

Rows can be removed from a table using the `DELETE` command. Suppose you are no longer interested in the weather of Hayward. Then you can do the following to delete those rows from the table:

```
DELETE FROM weather WHERE city = 'Hayward';
```

All weather records belonging to Hayward are removed.

```
SELECT * FROM weather;
```

city	temp_lo	temp_hi	prcp	date
San Francisco	46	50	0.25	1994-11-27
San Francisco	41	55	0	1994-11-29

(2 rows)

One should be wary of statements of the form

```
DELETE FROM tablename;
```

Without a qualification, `DELETE` will remove *all* rows from the given table, leaving it empty. The system will not request confirmation before doing this!

# Chapter 3. Advanced Features

## 3.1. Introduction

In the previous chapter we have covered the basics of using SQL to store and access your data in PostgreSQL. We will now discuss some more advanced features of SQL that simplify management and prevent loss or corruption of your data. Finally, we will look at some PostgreSQL extensions.

This chapter will on occasion refer to examples found in Chapter 2 to change or improve them, so it will be of advantage if you have read that chapter. Some examples from this chapter can also be found in `advanced.sql` in the tutorial directory. This file also contains some example data to load, which is not repeated here. (Refer to Section 2.1 for how to use the file.)

## 3.2. Views

Refer back to the queries in Section 2.6. Suppose the combined listing of weather records and city location is of particular interest to your application, but you do not want to type the query each time you need it. You can create a *view* over the query, which gives a name to the query that you can refer to like an ordinary table:

```
CREATE VIEW myview AS
    SELECT city, temp_lo, temp_hi, prcp, date, location
       FROM weather, cities
      WHERE city = name;

SELECT * FROM myview;
```

Making liberal use of views is a key aspect of good SQL database design. Views allow you to encapsulate the details of the structure of your tables, which might change as your application evolves, behind consistent interfaces.

Views can be used in almost any place a real table can be used. Building views upon other views is not uncommon.

## 3.3. Foreign Keys

Recall the `weather` and `cities` tables from Chapter 2. Consider the following problem: You want to make sure that no one can insert rows in the `weather` table that do not have a matching entry in the `cities` table. This is called maintaining the *referential integrity* of your data. In simplistic database systems this would be implemented (if at all) by first looking at the `cities` table to check if a matching record exists, and then inserting or rejecting the new `weather` records. This approach has a number of problems and is very inconvenient, so PostgreSQL can do this for you.

The new declaration of the tables would look like this:

```

CREATE TABLE cities (
    city      varchar(80) primary key,
    location  point
);

CREATE TABLE weather (
    city      varchar(80) references cities(city),
    temp_lo   int,
    temp_hi   int,
    prcp      real,
    date      date
);

```

Now try inserting an invalid record:

```
INSERT INTO weather VALUES ('Berkeley', 45, 53, 0.0, '1994-11-28');
```

```

ERROR:  insert or update on table "weather" violates foreign key constraint "weather_city_f
DETAIL:  Key (city)=(Berkeley) is not present in table "cities".

```

The behavior of foreign keys can be finely tuned to your application. We will not go beyond this simple example in this tutorial, but just refer you to Chapter 5 for more information. Making correct use of foreign keys will definitely improve the quality of your database applications, so you are strongly encouraged to learn about them.

## 3.4. Transactions

*Transactions* are a fundamental concept of all database systems. The essential point of a transaction is that it bundles multiple steps into a single, all-or-nothing operation. The intermediate states between the steps are not visible to other concurrent transactions, and if some failure occurs that prevents the transaction from completing, then none of the steps affect the database at all.

For example, consider a bank database that contains balances for various customer accounts, as well as total deposit balances for branches. Suppose that we want to record a payment of \$100.00 from Alice's account to Bob's account. Simplifying outrageously, the SQL commands for this might look like:

```

UPDATE accounts SET balance = balance - 100.00
    WHERE name = 'Alice';
UPDATE branches SET balance = balance - 100.00
    WHERE name = (SELECT branch_name FROM accounts WHERE name = 'Alice');
UPDATE accounts SET balance = balance + 100.00
    WHERE name = 'Bob';
UPDATE branches SET balance = balance + 100.00
    WHERE name = (SELECT branch_name FROM accounts WHERE name = 'Bob');

```

The details of these commands are not important here; the important point is that there are several separate updates involved to accomplish this rather simple operation. Our bank's officers will want to be assured that either all these updates happen, or none of them happen. It would certainly not do for a system failure

to result in Bob receiving \$100.00 that was not debited from Alice. Nor would Alice long remain a happy customer if she was debited without Bob being credited. We need a guarantee that if something goes wrong partway through the operation, none of the steps executed so far will take effect. Grouping the updates into a *transaction* gives us this guarantee. A transaction is said to be *atomic*: from the point of view of other transactions, it either happens completely or not at all.

We also want a guarantee that once a transaction is completed and acknowledged by the database system, it has indeed been permanently recorded and won't be lost even if a crash ensues shortly thereafter. For example, if we are recording a cash withdrawal by Bob, we do not want any chance that the debit to his account will disappear in a crash just after he walks out the bank door. A transactional database guarantees that all the updates made by a transaction are logged in permanent storage (i.e., on disk) before the transaction is reported complete.

Another important property of transactional databases is closely related to the notion of atomic updates: when multiple transactions are running concurrently, each one should not be able to see the incomplete changes made by others. For example, if one transaction is busy totalling all the branch balances, it would not do for it to include the debit from Alice's branch but not the credit to Bob's branch, nor vice versa. So transactions must be all-or-nothing not only in terms of their permanent effect on the database, but also in terms of their visibility as they happen. The updates made so far by an open transaction are invisible to other transactions until the transaction completes, whereupon all the updates become visible simultaneously.

In PostgreSQL, a transaction is set up by surrounding the SQL commands of the transaction with `BEGIN` and `COMMIT` commands. So our banking transaction would actually look like:

```
BEGIN;
UPDATE accounts SET balance = balance - 100.00
    WHERE name = 'Alice';
-- etc etc
COMMIT;
```

If, partway through the transaction, we decide we do not want to commit (perhaps we just noticed that Alice's balance went negative), we can issue the command `ROLLBACK` instead of `COMMIT`, and all our updates so far will be canceled.

PostgreSQL actually treats every SQL statement as being executed within a transaction. If you do not issue a `BEGIN` command, then each individual statement has an implicit `BEGIN` and (if successful) `COMMIT` wrapped around it. A group of statements surrounded by `BEGIN` and `COMMIT` is sometimes called a *transaction block*.

**Note:** Some client libraries issue `BEGIN` and `COMMIT` commands automatically, so that you might get the effect of transaction blocks without asking. Check the documentation for the interface you are using.

It's possible to control the statements in a transaction in a more granular fashion through the use of *savepoints*. Savepoints allow you to selectively discard parts of the transaction, while committing the rest. After defining a savepoint with `SAVEPOINT`, you can if needed roll back to the savepoint with `ROLLBACK TO`. All the transaction's database changes between defining the savepoint and rolling back to it are discarded, but changes earlier than the savepoint are kept.

After rolling back to a savepoint, it continues to be defined, so you can roll back to it several times. Conversely, if you are sure you won't need to roll back to a particular savepoint again, it can be released, so the system can free some resources. Keep in mind that either releasing or rolling back to a savepoint will automatically release all savepoints that were defined after it.

All this is happening within the transaction block, so none of it is visible to other database sessions. When and if you commit the transaction block, the committed actions become visible as a unit to other sessions, while the rolled-back actions never become visible at all.

Remembering the bank database, suppose we debit \$100.00 from Alice's account, and credit Bob's account, only to find later that we should have credited Wally's account. We could do it using savepoints like this:

```
BEGIN;
UPDATE accounts SET balance = balance - 100.00
    WHERE name = 'Alice';
SAVEPOINT my_savepoint;
UPDATE accounts SET balance = balance + 100.00
    WHERE name = 'Bob';
-- oops ... forget that and use Wally's account
ROLLBACK TO my_savepoint;
UPDATE accounts SET balance = balance + 100.00
    WHERE name = 'Wally';
COMMIT;
```

This example is, of course, oversimplified, but there's a lot of control to be had over a transaction block through the use of savepoints. Moreover, `ROLLBACK TO` is the only way to regain control of a transaction block that was put in aborted state by the system due to an error, short of rolling it back completely and starting again.

## 3.5. Inheritance

Inheritance is a concept from object-oriented databases. It opens up interesting new possibilities of database design.

Let's create two tables: A table `cities` and a table `capitals`. Naturally, capitals are also cities, so you want some way to show the capitals implicitly when you list all cities. If you're really clever you might invent some scheme like this:

```
CREATE TABLE capitals (
    name      text,
    population real,
    altitude  int,    -- (in ft)
    state     char(2)
);

CREATE TABLE non_capitals (
    name      text,
    population real,
    altitude  int    -- (in ft)
```

```
);

CREATE VIEW cities AS
  SELECT name, population, altitude FROM capitals
  UNION
  SELECT name, population, altitude FROM non_capitals;
```

This works OK as far as querying goes, but it gets ugly when you need to update several rows, for one thing.

A better solution is this:

```
CREATE TABLE cities (
  name      text,
  population real,
  altitude  int    -- (in ft)
);

CREATE TABLE capitals (
  state      char(2)
) INHERITS (cities);
```

In this case, a row of `capitals` *inherits* all columns (`name`, `population`, and `altitude`) from its *parent*, `cities`. The type of the column `name` is `text`, a native PostgreSQL type for variable length character strings. State capitals have an extra column, `state`, that shows their state. In PostgreSQL, a table can inherit from zero or more other tables.

For example, the following query finds the names of all cities, including state capitals, that are located at an altitude over 500 feet:

```
SELECT name, altitude
  FROM cities
 WHERE altitude > 500;
```

which returns:

name	altitude
Las Vegas	2174
Mariposa	1953
Madison	845

(3 rows)

On the other hand, the following query finds all the cities that are not state capitals and are situated at an altitude of 500 feet or higher:

```
SELECT name, altitude
  FROM ONLY cities
 WHERE altitude > 500;
```

name	altitude
------	----------

```

-----+-----
Las Vegas |      2174
Mariposa  |      1953
(2 rows)

```

Here the `ONLY` before `cities` indicates that the query should be run over only the `cities` table, and not tables below `cities` in the inheritance hierarchy. Many of the commands that we have already discussed — `SELECT`, `UPDATE`, and `DELETE` — support this `ONLY` notation.

**Note:** Although inheritance is frequently useful, it has not been integrated with unique constraints or foreign keys, which limits its usefulness. See Section 5.8 for more detail.

## 3.6. Conclusion

PostgreSQL has many features not touched upon in this tutorial introduction, which has been oriented toward newer users of SQL. These features are discussed in more detail in the remainder of this book.

If you feel you need more introductory material, please visit the PostgreSQL web site<sup>1</sup> for links to more resources.

## II. The SQL Language

This part describes the use of the SQL language in PostgreSQL. We start with describing the general syntax of SQL, then explain how to create the structures to hold data, how to populate the database, and how to query it. The middle part lists the available data types and functions for use in SQL commands. The rest treats several aspects that are important for tuning a database for optimal performance.

The information in this part is arranged so that a novice user can follow it start to end to gain a full understanding of the topics without having to refer forward too many times. The chapters are intended to be self-contained, so that advanced users can read the chapters individually as they choose. The information in this part is presented in a narrative fashion in topical units. Readers looking for a complete description of a particular command should look into Part VI.

Readers of this part should know how to connect to a PostgreSQL database and issue SQL commands. Readers that are unfamiliar with these issues are encouraged to read Part I first. SQL commands are typically entered using the PostgreSQL interactive terminal `psql`, but other programs that have similar functionality can be used as well.

# Chapter 4. SQL Syntax

This chapter describes the syntax of SQL. It forms the foundation for understanding the following chapters which will go into detail about how the SQL commands are applied to define and modify data.

We also advise users who are already familiar with SQL to read this chapter carefully because there are several rules and concepts that are implemented inconsistently among SQL databases or that are specific to PostgreSQL.

## 4.1. Lexical Structure

SQL input consists of a sequence of *commands*. A command is composed of a sequence of *tokens*, terminated by a semicolon (“;”). The end of the input stream also terminates a command. Which tokens are valid depends on the syntax of the particular command.

A token can be a *key word*, an *identifier*, a *quoted identifier*, a *literal* (or constant), or a special character symbol. Tokens are normally separated by whitespace (space, tab, newline), but need not be if there is no ambiguity (which is generally only the case if a special character is adjacent to some other token type).

Additionally, *comments* can occur in SQL input. They are not tokens, they are effectively equivalent to whitespace.

For example, the following is (syntactically) valid SQL input:

```
SELECT * FROM MY_TABLE;  
UPDATE MY_TABLE SET A = 5;  
INSERT INTO MY_TABLE VALUES (3, 'hi there');
```

This is a sequence of three commands, one per line (although this is not required; more than one command can be on a line, and commands can usefully be split across lines).

The SQL syntax is not very consistent regarding what tokens identify commands and which are operands or parameters. The first few tokens are generally the command name, so in the above example we would usually speak of a “SELECT”, an “UPDATE”, and an “INSERT” command. But for instance the `UPDATE` command always requires a `SET` token to appear in a certain position, and this particular variation of `INSERT` also requires a `VALUES` in order to be complete. The precise syntax rules for each command are described in Part VI.

### 4.1.1. Identifiers and Key Words

Tokens such as `SELECT`, `UPDATE`, or `VALUES` in the example above are examples of *key words*, that is, words that have a fixed meaning in the SQL language. The tokens `MY_TABLE` and `A` are examples of *identifiers*. They identify names of tables, columns, or other database objects, depending on the command they are used in. Therefore they are sometimes simply called “names”. Key words and identifiers have the same lexical structure, meaning that one cannot know whether a token is an identifier or a key word without knowing the language. A complete list of key words can be found in Appendix C.

SQL identifiers and key words must begin with a letter (a-z, but also letters with diacritical marks and non-Latin letters) or an underscore (\_). Subsequent characters in an identifier or key word can be letters, underscores, digits (0-9), or dollar signs (\$). Note that dollar signs are not allowed in identifiers according

to the letter of the SQL standard, so their use might render applications less portable. The SQL standard will not define a key word that contains digits or starts or ends with an underscore, so identifiers of this form are safe against possible conflict with future extensions of the standard.

The system uses no more than `NAMEDATALEN-1` bytes of an identifier; longer names can be written in commands, but they will be truncated. By default, `NAMEDATALEN` is 64 so the maximum identifier length is 63 bytes. If this limit is problematic, it can be raised by changing the `NAMEDATALEN` constant in `src/include/pg_config_manual.h`.

Identifier and key word names are case insensitive. Therefore:

```
UPDATE MY_TABLE SET A = 5;
```

can equivalently be written as:

```
uPDaTE my_Table SeT a = 5;
```

A convention often used is to write key words in upper case and names in lower case, e.g.:

```
UPDATE my_table SET a = 5;
```

There is a second kind of identifier: the *delimited identifier* or *quoted identifier*. It is formed by enclosing an arbitrary sequence of characters in double-quotes (`"`). A delimited identifier is always an identifier, never a key word. So `"select"` could be used to refer to a column or table named “select”, whereas an unquoted `select` would be taken as a key word and would therefore provoke a parse error when used where a table or column name is expected. The example can be written with quoted identifiers like this:

```
UPDATE "my_table" SET "a" = 5;
```

Quoted identifiers can contain any character, except the character with code zero. (To include a double quote, write two double quotes.) This allows constructing table or column names that would otherwise not be possible, such as ones containing spaces or ampersands. The length limitation still applies.

Quoting an identifier also makes it case-sensitive, whereas unquoted names are always folded to lower case. For example, the identifiers `FOO`, `fOO`, and `"fOO"` are considered the same by PostgreSQL, but `"FOO"` and `"FOO"` are different from these three and each other. (The folding of unquoted names to lower case in PostgreSQL is incompatible with the SQL standard, which says that unquoted names should be folded to upper case. Thus, `fOO` should be equivalent to `"FOO"` not `"fOO"` according to the standard. If you want to write portable applications you are advised to always quote a particular name or never quote it.)

### 4.1.2. Constants

There are three kinds of *implicitly-typed constants* in PostgreSQL: strings, bit strings, and numbers. Constants can also be specified with explicit types, which can enable more accurate representation and more efficient handling by the system. These alternatives are discussed in the following subsections.

### 4.1.2.1. String Constants

A string constant in SQL is an arbitrary sequence of characters bounded by single quotes ('), for example 'This is a string'. To include a single-quote character within a string constant, write two adjacent single quotes, e.g. 'Dianne"s horse'. Note that this is *not* the same as a double-quote character (").

Two string constants that are only separated by whitespace *with at least one newline* are concatenated and effectively treated as if the string had been written as one constant. For example:

```
SELECT 'foo'
'bar' ;
```

is equivalent to:

```
SELECT 'foobar' ;
```

but:

```
SELECT 'foo'      'bar' ;
```

is not valid syntax. (This slightly bizarre behavior is specified by SQL; PostgreSQL is following the standard.)

PostgreSQL also accepts “escape” string constants, which are an extension to the SQL standard. An escape string constant is specified by writing the letter E (upper or lower case) just before the opening single quote, e.g. E'foo'. (When continuing an escape string constant across lines, write E only before the first opening quote.) Within an escape string, a backslash character (\) begins a C-like *backslash escape* sequence, in which the combination of backslash and following character(s) represents a special byte value. \b is a backspace, \f is a form feed, \n is a newline, \r is a carriage return, \t is a tab. Also supported are \digits, where digits represents an octal byte value, and \xhexdigits, where hexdigits represents a hexadecimal byte value. (It is your responsibility that the byte sequences you create are valid characters in the server character set encoding.) Any other character following a backslash is taken literally. Thus, to include a backslash character, write two backslashes (\\). Also, a single quote can be included in an escape string by writing \', in addition to the normal way of ".

#### Caution

If the configuration parameter `standard_conforming_strings` is `off`, then PostgreSQL recognizes backslash escapes in both regular and escape string constants. This is for backward compatibility with the historical behavior, in which backslash escapes were always recognized. Although `standard_conforming_strings` currently defaults to `off`, the default will change to `on` in a future release for improved standards compliance. Applications are therefore encouraged to migrate away from using backslash escapes. If you need to use a backslash escape to represent a special character, write the constant with an E to be sure it will be handled the same way in future releases.

In addition to `standard_conforming_strings`, the configuration parameters `escape_string_warning` and `backslash_quote` govern treatment of backslashes in string constants.

The character with the code zero cannot be in a string constant.

### 4.1.2.2. Dollar-Quoted String Constants

While the standard syntax for specifying string constants is usually convenient, it can be difficult to understand when the desired string contains many single quotes or backslashes, since each of those must be doubled. To allow more readable queries in such situations, PostgreSQL provides another way, called “dollar quoting”, to write string constants. A dollar-quoted string constant consists of a dollar sign (\$), an optional “tag” of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. For example, here are two different ways to specify the string “Dianne’s horse” using dollar quoting:

```
$Dianne's horse$
$SomeTag$Dianne's horse$SomeTag$
```

Notice that inside the dollar-quoted string, single quotes can be used without needing to be escaped. Indeed, no characters inside a dollar-quoted string are ever escaped: the string content is always written literally. Backslashes are not special, and neither are dollar signs, unless they are part of a sequence matching the opening tag.

It is possible to nest dollar-quoted string constants by choosing different tags at each nesting level. This is most commonly used in writing function definitions. For example:

```
$function$
BEGIN
    RETURN ($1 ~ $q$[\t\r\n\v\\]$q$);
END;
$function$
```

Here, the sequence `$q$[\t\r\n\v\\]$q$` represents a dollar-quoted literal string `[\t\r\n\v\\]`, which will be recognized when the function body is executed by PostgreSQL. But since the sequence does not match the outer dollar quoting delimiter `$function$`, it is just some more characters within the constant so far as the outer string is concerned.

The tag, if any, of a dollar-quoted string follows the same rules as an unquoted identifier, except that it cannot contain a dollar sign. Tags are case sensitive, so `$tag$string content$tag$` is correct, but `$TAG$string content$tag$` is not.

A dollar-quoted string that follows a keyword or identifier must be separated from it by whitespace; otherwise the dollar quoting delimiter would be taken as part of the preceding identifier.

Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax. It is particularly useful when representing string constants inside other constants, as is often needed in procedural function definitions. With single-quote syntax, each backslash in the above example would have to be written as four backslashes, which would be reduced to two backslashes in parsing the original string constant, and then to one when the inner string constant is re-parsed during function execution.

### 4.1.2.3. Bit-String Constants

Bit-string constants look like regular string constants with a `B` (upper or lower case) immediately before the opening quote (no intervening whitespace), e.g., `B'1001'`. The only characters allowed within bit-string constants are 0 and 1.

Alternatively, bit-string constants can be specified in hexadecimal notation, using a leading `x` (upper or lower case), e.g., `x'1FF'`. This notation is equivalent to a bit-string constant with four binary digits for each hexadecimal digit.

Both forms of bit-string constant can be continued across lines in the same way as regular string constants. Dollar quoting cannot be used in a bit-string constant.

#### 4.1.2.4. Numeric Constants

Numeric constants are accepted in these general forms:

```
digits
digits.[digits][e[+-]digits]
[digits].digits[e[+-]digits]
digitse[+-]digits
```

where *digits* is one or more decimal digits (0 through 9). At least one digit must be before or after the decimal point, if one is used. At least one digit must follow the exponent marker (e), if one is present. There cannot be any spaces or other characters embedded in the constant. Note that any leading plus or minus sign is not actually considered part of the constant; it is an operator applied to the constant.

These are some examples of valid numeric constants:

```
42
3.5
4.
.001
5e2
1.925e-3
```

A numeric constant that contains neither a decimal point nor an exponent is initially presumed to be type `integer` if its value fits in type `integer` (32 bits); otherwise it is presumed to be type `bigint` if its value fits in type `bigint` (64 bits); otherwise it is taken to be type `numeric`. Constants that contain decimal points and/or exponents are always initially presumed to be type `numeric`.

The initially assigned data type of a numeric constant is just a starting point for the type resolution algorithms. In most cases the constant will be automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it. For example, you can force a numeric value to be treated as type `real` (`float4`) by writing:

```
REAL '1.23'  -- string style
1.23::REAL  -- PostgreSQL (historical) style
```

These are actually just special cases of the general casting notations discussed next.

### 4.1.2.5. Constants of Other Types

A constant of an *arbitrary* type can be entered using any one of the following notations:

```
type 'string'
'string'::type
CAST ( 'string' AS type )
```

The string constant's text is passed to the input conversion routine for the type called *type*. The result is a constant of the indicated type. The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be (for example, when it is assigned directly to a table column), in which case it is automatically coerced.

The string constant can be written using either regular SQL notation or dollar-quoting.

It is also possible to specify a type coercion using a function-like syntax:

```
typename ( 'string' )
```

but not all type names can be used in this way; see Section 4.2.8 for details.

The `::`, `CAST()`, and function-call syntaxes can also be used to specify run-time type conversions of arbitrary expressions, as discussed in Section 4.2.8. To avoid syntactic ambiguity, the `type 'string'` syntax can only be used to specify the type of a simple literal constant. Another restriction on the `type 'string'` syntax is that it does not work for array types; use `::` or `CAST()` to specify the type of an array constant.

The `CAST()` syntax conforms to SQL. The `type 'string'` syntax is a generalization of the standard: SQL specifies this syntax only for a few data types, but PostgreSQL allows it for all types. The syntax with `::` is historical PostgreSQL usage, as is the function-call syntax.

### 4.1.3. Operators

An operator name is a sequence of up to `NAMEDATALEN-1` (63 by default) characters from the following list:

```
+ - * / < > = ~ ! @ # % ^ & | ' ?
```

There are a few restrictions on operator names, however:

- `--` and `/*` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multiple-character operator name cannot end in `+` or `-`, unless the name also contains at least one of these characters:

```
~ ! @ # % ^ & | ' ?
```

For example, `@-` is an allowed operator name, but `*-` is not. This restriction allows PostgreSQL to parse SQL-compliant queries without requiring spaces between tokens.

When working with non-SQL-standard operator names, you will usually need to separate adjacent operators with spaces to avoid ambiguity. For example, if you have defined a left unary operator named @, you cannot write `X*@Y`; you must write `X* @Y` to ensure that PostgreSQL reads it as two operator names not one.

#### 4.1.4. Special Characters

Some characters that are not alphanumeric have a special meaning that is different from being an operator. Details on the usage can be found at the location where the respective syntax element is described. This section only exists to advise the existence and summarize the purposes of these characters.

- A dollar sign (\$) followed by digits is used to represent a positional parameter in the body of a function definition or a prepared statement. In other contexts the dollar sign can be part of an identifier or a dollar-quoted string constant.
- Parentheses (()) have their usual meaning to group expressions and enforce precedence. In some cases parentheses are required as part of the fixed syntax of a particular SQL command.
- Brackets ([]) are used to select the elements of an array. See Section 8.14 for more information on arrays.
- Commas (,) are used in some syntactical constructs to separate the elements of a list.
- The semicolon (;) terminates an SQL command. It cannot appear anywhere within a command, except within a string constant or quoted identifier.
- The colon (:) is used to select “slices” from arrays. (See Section 8.14.) In certain SQL dialects (such as Embedded SQL), the colon is used to prefix variable names.
- The asterisk (\*) is used in some contexts to denote all the fields of a table row or composite value. It also has a special meaning when used as the argument of an aggregate function, namely that the aggregate does not require any explicit parameter.
- The period (.) is used in numeric constants, and to separate schema, table, and column names.

#### 4.1.5. Comments

A comment is an arbitrary sequence of characters beginning with double dashes and extending to the end of the line, e.g.:

```
-- This is a standard SQL comment
```

Alternatively, C-style block comments can be used:

```
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

where the comment begins with `/*` and extends to the matching occurrence of `*/`. These block comments nest, as specified in the SQL standard but unlike C, so that one can comment out larger blocks of code that might contain existing block comments.

A comment is removed from the input stream before further syntax analysis and is effectively replaced by whitespace.

### 4.1.6. Lexical Precedence

Table 4-1 shows the precedence and associativity of the operators in PostgreSQL. Most operators have the same precedence and are left-associative. The precedence and associativity of the operators is hard-wired into the parser. This can lead to non-intuitive behavior; for example the Boolean operators `<` and `>` have a different precedence than the Boolean operators `<=` and `>=`. Also, you will sometimes need to add parentheses when using combinations of binary and unary operators. For instance:

```
SELECT 5 ! - 6;
```

will be parsed as:

```
SELECT 5 ! (- 6);
```

because the parser has no idea — until it is too late — that `!` is defined as a postfix operator, not an infix one. To get the desired behavior in this case, you must write:

```
SELECT (5 !) - 6;
```

This is the price one pays for extensibility.

**Table 4-1. Operator Precedence (decreasing)**

Operator/Element	Associativity	Description
<code>.</code>	left	table/column name separator
<code>::</code>	left	PostgreSQL-style typecast
<code>[ ]</code>	left	array element selection
<code>-</code>	right	unary minus
<code>^</code>	left	exponentiation
<code>* / %</code>	left	multiplication, division, modulo
<code>+ -</code>	left	addition, subtraction
<code>IS</code>		<code>IS TRUE</code> , <code>IS FALSE</code> , <code>IS UNKNOWN</code> , <code>IS NULL</code>
<code>ISNULL</code>		test for null
<code>NOTNULL</code>		test for not null
(any other)	left	all other native and user-defined operators
<code>IN</code>		set membership
<code>BETWEEN</code>		range containment

Operator/Element	Associativity	Description
OVERLAPS		time interval overlap
LIKE ILIKE SIMILAR		string pattern matching
< >		less than, greater than
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

Note that the operator precedence rules also apply to user-defined operators that have the same names as the built-in operators mentioned above. For example, if you define a “+” operator for some custom data type it will have the same precedence as the built-in “+” operator, no matter what yours does.

When a schema-qualified operator name is used in the `OPERATOR` syntax, as for example in:

```
SELECT 3 OPERATOR(pg_catalog.+) 4;
```

the `OPERATOR` construct is taken to have the default precedence shown in Table 4-1 for “any other” operator. This is true no matter which specific operator name appears inside `OPERATOR()`.

## 4.2. Value Expressions

Value expressions are used in a variety of contexts, such as in the target list of the `SELECT` command, as new column values in `INSERT` or `UPDATE`, or in search conditions in a number of commands. The result of a value expression is sometimes called a *scalar*, to distinguish it from the result of a table expression (which is a table). Value expressions are therefore also called *scalar expressions* (or even simply *expressions*). The expression syntax allows the calculation of values from primitive parts using arithmetic, logical, set, and other operations.

A value expression is one of the following:

- A constant or literal value.
- A column reference.
- A positional parameter reference, in the body of a function definition or prepared statement.
- A subscripted expression.
- A field selection expression.
- An operator invocation.
- A function call.
- An aggregate expression.
- A type cast.
- A scalar subquery.
- An array constructor.

- A row constructor.
- Another value expression in parentheses, useful to group subexpressions and override precedence.

In addition to this list, there are a number of constructs that can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator and are explained in the appropriate location in Chapter 9. An example is the `IS NULL` clause.

We have already discussed constants in Section 4.1.2. The following sections discuss the remaining options.

### 4.2.1. Column References

A column can be referenced in the form

*correlation.columnname*

*correlation* is the name of a table (possibly qualified with a schema name), or an alias for a table defined by means of a `FROM` clause, or one of the key words `NEW` or `OLD`. (`NEW` and `OLD` can only appear in rewrite rules, while other correlation names can be used in any SQL statement.) The correlation name and separating dot can be omitted if the column name is unique across all the tables being used in the current query. (See also Chapter 7.)

### 4.2.2. Positional Parameters

A positional parameter reference is used to indicate a value that is supplied externally to an SQL statement. Parameters are used in SQL function definitions and in prepared queries. Some client libraries also support specifying data values separately from the SQL command string, in which case parameters are used to refer to the out-of-line data values. The form of a parameter reference is:

*\$number*

For example, consider the definition of a function, `dept`, as:

```
CREATE FUNCTION dept(text) RETURNS dept
  AS $$ SELECT * FROM dept WHERE name = $1 $$
LANGUAGE SQL;
```

Here the `$1` references the value of the first function argument whenever the function is invoked.

### 4.2.3. Subscripts

If an expression yields a value of an array type, then a specific element of the array value can be extracted by writing

```
expression[subscript]
```

or multiple adjacent elements (an “array slice”) can be extracted by writing

```
expression[lower_subscript:upper_subscript]
```

(Here, the brackets [ ] are meant to appear literally.) Each *subscript* is itself an expression, which must yield an integer value.

In general the array *expression* must be parenthesized, but the parentheses can be omitted when the expression to be subscripted is just a column reference or positional parameter. Also, multiple subscripts can be concatenated when the original array is multidimensional. For example:

```
mytable.arraycolumn[4]
mytable.two_d_column[17][34]
$1[10:42]
(arrayfunction(a,b))[42]
```

The parentheses in the last example are required. See Section 8.14 for more about arrays.

### 4.2.4. Field Selection

If an expression yields a value of a composite type (row type), then a specific field of the row can be extracted by writing

```
expression.fieldname
```

In general the row *expression* must be parenthesized, but the parentheses can be omitted when the expression to be selected from is just a table reference or positional parameter. For example:

```
mytable.mycolumn
$1.somecolumn
(rowfunction(a,b)).col3
```

(Thus, a qualified column reference is actually just a special case of the field selection syntax.)

### 4.2.5. Operator Invocations

There are three possible syntaxes for an operator invocation:

```
expression operator expression (binary infix operator)
operator expression (unary prefix operator)
expression operator (unary postfix operator)
```

where the *operator* token follows the syntax rules of Section 4.1.3, or is one of the key words AND, OR, and NOT, or is a qualified operator name in the form

```
OPERATOR (schema.operatorname)
```

Which particular operators exist and whether they are unary or binary depends on what operators have been defined by the system or the user. Chapter 9 describes the built-in operators.

## 4.2.6. Function Calls

The syntax for a function call is the name of a function (possibly qualified with a schema name), followed by its argument list enclosed in parentheses:

```
function ([expression [, expression ... ] ] )
```

For example, the following computes the square root of 2:

```
sqrt (2)
```

The list of built-in functions is in Chapter 9. Other functions can be added by the user.

## 4.2.7. Aggregate Expressions

An *aggregate expression* represents the application of an aggregate function across the rows selected by a query. An aggregate function reduces multiple inputs to a single output value, such as the sum or average of the inputs. The syntax of an aggregate expression is one of the following:

```
aggregate_name (expression [ , ... ] )
aggregate_name (ALL expression [ , ... ] )
aggregate_name (DISTINCT expression [ , ... ] )
aggregate_name ( * )
```

where *aggregate\_name* is a previously defined aggregate (possibly qualified with a schema name), and *expression* is any value expression that does not itself contain an aggregate expression.

The first form of aggregate expression invokes the aggregate across all input rows for which the given expression(s) yield non-null values. (Actually, it is up to the aggregate function whether to ignore null values or not — but all the standard ones do.) The second form is the same as the first, since ALL is the default. The third form invokes the aggregate for all distinct non-null values of the expressions found in the input rows. The last form invokes the aggregate once for each input row regardless of null or non-null values; since no particular input value is specified, it is generally only useful for the count (\*) aggregate function.

For example, count (\*) yields the total number of input rows; count (f1) yields the number of input rows in which f1 is non-null; count (distinct f1) yields the number of distinct non-null values of f1.

The predefined aggregate functions are described in Section 9.18. Other aggregate functions can be added by the user.

An aggregate expression can only appear in the result list or `HAVING` clause of a `SELECT` command. It is forbidden in other clauses, such as `WHERE`, because those clauses are logically evaluated before the results of aggregates are formed.

When an aggregate expression appears in a subquery (see Section 4.2.9 and Section 9.19), the aggregate is normally evaluated over the rows of the subquery. But an exception occurs if the aggregate's arguments contain only outer-level variables: the aggregate then belongs to the nearest such outer level, and is evaluated over the rows of that query. The aggregate expression as a whole is then an outer reference for the subquery it appears in, and acts as a constant over any one evaluation of that subquery. The restriction about appearing only in the result list or `HAVING` clause applies with respect to the query level that the aggregate belongs to.

**Note:** PostgreSQL currently does not support `DISTINCT` with more than one input expression.

## 4.2.8. Type Casts

A type cast specifies a conversion from one data type to another. PostgreSQL accepts two equivalent syntaxes for type casts:

```
CAST ( expression AS type )
expression::type
```

The `CAST` syntax conforms to SQL; the syntax with `::` is historical PostgreSQL usage.

When a cast is applied to a value expression of a known type, it represents a run-time type conversion. The cast will succeed only if a suitable type conversion operation has been defined. Notice that this is subtly different from the use of casts with constants, as shown in Section 4.1.2.5. A cast applied to an unadorned string literal represents the initial assignment of a type to a literal constant value, and so it will succeed for any type (if the contents of the string literal are acceptable input syntax for the data type).

An explicit type cast can usually be omitted if there is no ambiguity as to the type that a value expression must produce (for example, when it is assigned to a table column); the system will automatically apply a type cast in such cases. However, automatic casting is only done for casts that are marked “OK to apply implicitly” in the system catalogs. Other casts must be invoked with explicit casting syntax. This restriction is intended to prevent surprising conversions from being applied silently.

It is also possible to specify a type cast using a function-like syntax:

```
typename ( expression )
```

However, this only works for types whose names are also valid as function names. For example, `double precision` cannot be used this way, but the equivalent `float8` can. Also, the names `interval`, `time`, and `timestamp` can only be used in this fashion if they are double-quoted, because of syntactic conflicts. Therefore, the use of the function-like cast syntax leads to inconsistencies and should probably be avoided in new applications.

**Note:** The function-like syntax is in fact just a function call. When one of the two standard cast syntaxes is used to do a run-time conversion, it will internally invoke a registered function to perform the conversion. By convention, these conversion functions have the same name as their output type, and thus the “function-like syntax” is nothing more than a direct invocation of the underlying conversion function. Obviously, this is not something that a portable application should rely on. For further details see *CREATE CAST*.

## 4.2.9. Scalar Subqueries

A scalar subquery is an ordinary `SELECT` query in parentheses that returns exactly one row with one column. (See Chapter 7 for information about writing queries.) The `SELECT` query is executed and the single returned value is used in the surrounding value expression. It is an error to use a query that returns more than one row or more than one column as a scalar subquery. (But if, during a particular execution, the subquery returns no rows, there is no error; the scalar result is taken to be null.) The subquery can refer to variables from the surrounding query, which will act as constants during any one evaluation of the subquery. See also Section 9.19 for other expressions involving subqueries.

For example, the following finds the largest city population in each state:

```
SELECT name, (SELECT max(pop) FROM cities WHERE cities.state = states.name)
FROM states;
```

## 4.2.10. Array Constructors

An array constructor is an expression that builds an array value from values for its member elements. A simple array constructor consists of the key word `ARRAY`, a left square bracket `[`, one or more expressions (separated by commas) for the array element values, and finally a right square bracket `]`. For example:

```
SELECT ARRAY[1,2,3+4];
array
-----
{1,2,7}
(1 row)
```

The array element type is the common type of the member expressions, determined using the same rules as for `UNION` or `CASE` constructs (see Section 10.5).

Multidimensional array values can be built by nesting array constructors. In the inner constructors, the key word `ARRAY` can be omitted. For example, these produce the same result:

```
SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
array
-----
{{1,2},{3,4}}
(1 row)
```

```
SELECT ARRAY[[1,2],[3,4]];
      array
-----
 {{1,2},{3,4}}
(1 row)
```

Since multidimensional arrays must be rectangular, inner constructors at the same level must produce sub-arrays of identical dimensions.

Multidimensional array constructor elements can be anything yielding an array of the proper kind, not only a sub-ARRAY construct. For example:

```
CREATE TABLE arr(f1 int[], f2 int[]);

INSERT INTO arr VALUES (ARRAY[[1,2],[3,4]], ARRAY[[5,6],[7,8]]);

SELECT ARRAY[f1, f2, '{{9,10},{11,12}}'::int[]] FROM arr;
      array
-----
 {{1,2},{3,4}},{5,6},{7,8}},{9,10},{11,12}}
(1 row)
```

It is also possible to construct an array from the results of a subquery. In this form, the array constructor is written with the key word `ARRAY` followed by a parenthesized (not bracketed) subquery. For example:

```
SELECT ARRAY(SELECT oid FROM pg_proc WHERE proname LIKE 'bytea%');
      ?column?
-----
 {2011,1954,1948,1952,1951,1244,1950,2005,1949,1953,2006,31}
(1 row)
```

The subquery must return a single column. The resulting one-dimensional array will have an element for each row in the subquery result, with an element type matching that of the subquery's output column.

The subscripts of an array value built with `ARRAY` always begin with one. For more information about arrays, see Section 8.14.

## 4.2.11. Row Constructors

A row constructor is an expression that builds a row value (also called a composite value) from values for its member fields. A row constructor consists of the key word `ROW`, a left parenthesis, zero or more expressions (separated by commas) for the row field values, and finally a right parenthesis. For example:

```
SELECT ROW(1,2.5,'this is a test');
```

The key word `ROW` is optional when there is more than one expression in the list.

A row constructor can include the syntax `rowvalue.*`, which will be expanded to a list of the elements of the row value, just as occurs when the `.*` syntax is used at the top level of a `SELECT` list. For example, if table `t` has columns `f1` and `f2`, these are the same:

```
SELECT ROW(t.*, 42) FROM t;
SELECT ROW(t.f1, t.f2, 42) FROM t;
```

**Note:** Before PostgreSQL 8.2, the `.*` syntax was not expanded, so that writing `ROW(t.*, 42)` created a two-field row whose first field was another row value. The new behavior is usually more useful. If you need the old behavior of nested row values, write the inner row value without `.*`, for instance `ROW(t, 42)`.

By default, the value created by a `ROW` expression is of an anonymous record type. If necessary, it can be cast to a named composite type — either the row type of a table, or a composite type created with `CREATE TYPE AS`. An explicit cast might be needed to avoid ambiguity. For example:

```
CREATE TABLE mytable(f1 int, f2 float, f3 text);

CREATE FUNCTION getf1(mytable) RETURNS int AS 'SELECT $1.f1' LANGUAGE SQL;

-- No cast needed since only one getf1() exists
SELECT getf1(ROW(1,2.5,'this is a test'));
getf1
-----
      1
(1 row)

CREATE TYPE myrowtype AS (f1 int, f2 text, f3 numeric);

CREATE FUNCTION getf1(myrowtype) RETURNS int AS 'SELECT $1.f1' LANGUAGE SQL;

-- Now we need a cast to indicate which function to call:
SELECT getf1(ROW(1,2.5,'this is a test'));
ERROR:  function getf1(record) is not unique

SELECT getf1(ROW(1,2.5,'this is a test')::mytable);
getf1
-----
      1
(1 row)

SELECT getf1(CAST(ROW(11,'this is a test',2.5) AS myrowtype));
getf1
-----
     11
(1 row)
```

Row constructors can be used to build composite values to be stored in a composite-type table column, or to be passed to a function that accepts a composite parameter. Also, it is possible to compare two row values or test a row with `IS NULL` or `IS NOT NULL`, for example:

```
SELECT ROW(1,2.5,'this is a test') = ROW(1, 3, 'not the same');
```

```
SELECT ROW(table.*) IS NULL FROM table; -- detect all-null rows
```

For more detail see Section 9.20. Row constructors can also be used in connection with subqueries, as discussed in Section 9.19.

## 4.2.12. Expression Evaluation Rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order.

Furthermore, if the result of an expression can be determined by evaluating only some parts of it, then other subexpressions might not be evaluated at all. For instance, if one wrote:

```
SELECT true OR somefunc();
```

then `somefunc()` would (probably) not be called at all. The same would be the case if one wrote:

```
SELECT somefunc() OR true;
```

Note that this is not the same as the left-to-right “short-circuiting” of Boolean operators that is found in some programming languages.

As a consequence, it is unwise to use functions with side effects as part of complex expressions. It is particularly dangerous to rely on side effects or evaluation order in `WHERE` and `HAVING` clauses, since those clauses are extensively reprocessed as part of developing an execution plan. Boolean expressions (`AND/OR/NOT` combinations) in those clauses can be reorganized in any manner allowed by the laws of Boolean algebra.

When it is essential to force evaluation order, a `CASE` construct (see Section 9.16) can be used. For example, this is an untrustworthy way of trying to avoid division by zero in a `WHERE` clause:

```
SELECT ... WHERE x > 0 AND y/x > 1.5;
```

But this is safe:

```
SELECT ... WHERE CASE WHEN x > 0 THEN y/x > 1.5 ELSE false END;
```

A `CASE` construct used in this fashion will defeat optimization attempts, so it should only be done when necessary. (In this particular example, it would be better to sidestep the problem by writing `y > 1.5*x` instead.)

# Chapter 5. Data Definition

This chapter covers how one creates the database structures that will hold one's data. In a relational database, the raw data is stored in tables, so the majority of this chapter is devoted to explaining how tables are created and modified and what features are available to control what data is stored in the tables. Subsequently, we discuss how tables can be organized into schemas, and how privileges can be assigned to tables. Finally, we will briefly look at other features that affect the data storage, such as inheritance, views, functions, and triggers.

## 5.1. Table Basics

A table in a relational database is much like a table on paper: It consists of rows and columns. The number and order of the columns is fixed, and each column has a name. The number of rows is variable — it reflects how much data is stored at a given moment. SQL does not make any guarantees about the order of the rows in a table. When a table is read, the rows will appear in random order, unless sorting is explicitly requested. This is covered in Chapter 7. Furthermore, SQL does not assign unique identifiers to rows, so it is possible to have several completely identical rows in a table. This is a consequence of the mathematical model that underlies SQL but is usually not desirable. Later in this chapter we will see how to deal with this issue.

Each column has a data type. The data type constrains the set of possible values that can be assigned to a column and assigns semantics to the data stored in the column so that it can be used for computations. For instance, a column declared to be of a numerical type will not accept arbitrary text strings, and the data stored in such a column can be used for mathematical computations. By contrast, a column declared to be of a character string type will accept almost any kind of data but it does not lend itself to mathematical calculations, although other operations such as string concatenation are available.

PostgreSQL includes a sizable set of built-in data types that fit many applications. Users can also define their own data types. Most built-in data types have obvious names and semantics, so we defer a detailed explanation to Chapter 8. Some of the frequently used data types are `integer` for whole numbers, `numeric` for possibly fractional numbers, `text` for character strings, `date` for dates, `time` for time-of-day values, and `timestamp` for values containing both date and time.

To create a table, you use the aptly named *CREATE TABLE* command. In this command you specify at least a name for the new table, the names of the columns and the data type of each column. For example:

```
CREATE TABLE my_first_table (  
    first_column text,  
    second_column integer  
);
```

This creates a table named `my_first_table` with two columns. The first column is named `first_column` and has a data type of `text`; the second column has the name `second_column` and the type `integer`. The table and column names follow the identifier syntax explained in Section 4.1.1. The type names are usually also identifiers, but there are some exceptions. Note that the column list is comma-separated and surrounded by parentheses.

Of course, the previous example was heavily contrived. Normally, you would give names to your tables and columns that convey what kind of data they store. So let's look at a more realistic example:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric
);
```

(The `numeric` type can store fractional components, as would be typical of monetary amounts.)

**Tip:** When you create many interrelated tables it is wise to choose a consistent naming pattern for the tables and columns. For instance, there is a choice of using singular or plural nouns for table names, both of which are favored by some theorist or other.

There is a limit on how many columns a table can contain. Depending on the column types, it is between 250 and 1600. However, defining a table with anywhere near this many columns is highly unusual and often a questionable design.

If you no longer need a table, you can remove it using the *DROP TABLE* command. For example:

```
DROP TABLE my_first_table;
DROP TABLE products;
```

Attempting to drop a table that does not exist is an error. Nevertheless, it is common in SQL script files to unconditionally try to drop each table before creating it, ignoring any error messages, so that the script works whether or not the table exists. (If you like, you can use the `DROP TABLE IF EXISTS` variant to avoid the error messages, but this is not standard SQL.)

If you need to modify a table that already exists look into Section 5.5 later in this chapter.

With the tools discussed so far you can create fully functional tables. The remainder of this chapter is concerned with adding features to the table definition to ensure data integrity, security, or convenience. If you are eager to fill your tables with data now you can skip ahead to Chapter 6 and read the rest of this chapter later.

## 5.2. Default Values

A column can be assigned a default value. When a new row is created and no values are specified for some of the columns, those columns will be filled with their respective default values. A data manipulation command can also request explicitly that a column be set to its default value, without having to know what that value is. (Details about data manipulation commands are in Chapter 6.)

If no default value is declared explicitly, the default value is the null value. This usually makes sense because a null value can be considered to represent unknown data.

In a table definition, default values are listed after the column data type. For example:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric DEFAULT 9.99
);
```

The default value can be an expression, which will be evaluated whenever the default value is inserted (*not* when the table is created). A common example is that a `timestamp` column can have a default of `now()`, so that it gets set to the time of row insertion. Another common example is generating a “serial number” for each row. In PostgreSQL this is typically done by something like:

```
CREATE TABLE products (
    product_no integer DEFAULT nextval('products_product_no_seq'),
    ...
);
```

where the `nextval()` function supplies successive values from a *sequence object* (see Section 9.15). This arrangement is sufficiently common that there’s a special shorthand for it:

```
CREATE TABLE products (
    product_no SERIAL,
    ...
);
```

The `SERIAL` shorthand is discussed further in Section 8.1.4.

## 5.3. Constraints

Data types are a way to limit the kind of data that can be stored in a table. For many applications, however, the constraint they provide is too coarse. For example, a column containing a product price should probably only accept positive values. But there is no standard data type that accepts only positive numbers. Another issue is that you might want to constrain column data with respect to other columns or rows. For example, in a table containing product information, there should be only one row for each product number.

To that end, SQL allows you to define constraints on columns and tables. Constraints give you as much control over the data in your tables as you wish. If a user attempts to store data in a column that would violate a constraint, an error is raised. This applies even if the value came from the default value definition.

### 5.3.1. Check Constraints

A check constraint is the most generic constraint type. It allows you to specify that the value in a certain column must satisfy a Boolean (truth-value) expression. For instance, to require positive product prices, you could use:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric CHECK (price > 0)
);
```

As you see, the constraint definition comes after the data type, just like default value definitions. Default values and constraints can be listed in any order. A check constraint consists of the key word `CHECK` followed by an expression in parentheses. The check constraint expression should involve the column thus constrained, otherwise the constraint would not make too much sense.

You can also give the constraint a separate name. This clarifies error messages and allows you to refer to the constraint when you need to change it. The syntax is:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric CONSTRAINT positive_price CHECK (price > 0)
);
```

So, to specify a named constraint, use the key word `CONSTRAINT` followed by an identifier followed by the constraint definition. (If you don't specify a constraint name in this way, the system chooses a name for you.)

A check constraint can also refer to several columns. Say you store a regular price and a discounted price, and you want to ensure that the discounted price is lower than the regular price:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric CHECK (price > 0),
    discounted_price numeric CHECK (discounted_price > 0),
    CHECK (price > discounted_price)
);
```

The first two constraints should look familiar. The third one uses a new syntax. It is not attached to a particular column, instead it appears as a separate item in the comma-separated column list. Column definitions and these constraint definitions can be listed in mixed order.

We say that the first two constraints are column constraints, whereas the third one is a table constraint because it is written separately from any one column definition. Column constraints can also be written as table constraints, while the reverse is not necessarily possible, since a column constraint is supposed to refer to only the column it is attached to. (PostgreSQL doesn't enforce that rule, but you should follow it if you want your table definitions to work with other database systems.) The above example could also be written as:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric,
    CHECK (price > 0),
    discounted_price numeric,
    CHECK (discounted_price > 0),
    CHECK (price > discounted_price)
);
```

or even:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric CHECK (price > 0),
    discounted_price numeric,
    CHECK (discounted_price > 0 AND price > discounted_price)
);
```

It's a matter of taste.

Names can be assigned to table constraints in just the same way as for column constraints:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric,
    CHECK (price > 0),
    discounted_price numeric,
    CHECK (discounted_price > 0),
    CONSTRAINT valid_discount CHECK (price > discounted_price)
);
```

It should be noted that a check constraint is satisfied if the check expression evaluates to true or the null value. Since most expressions will evaluate to the null value if any operand is null, they will not prevent null values in the constrained columns. To ensure that a column does not contain null values, the not-null constraint described in the next section can be used.

### 5.3.2. Not-Null Constraints

A not-null constraint simply specifies that a column must not assume the null value. A syntax example:

```
CREATE TABLE products (
    product_no integer NOT NULL,
    name text NOT NULL,
    price numeric
);
```

A not-null constraint is always written as a column constraint. A not-null constraint is functionally equivalent to creating a check constraint `CHECK (column_name IS NOT NULL)`, but in PostgreSQL creating an explicit not-null constraint is more efficient. The drawback is that you cannot give explicit names to not-null constraints created this way.

Of course, a column can have more than one constraint. Just write the constraints one after another:

```
CREATE TABLE products (
    product_no integer NOT NULL,
    name text NOT NULL,
    price numeric NOT NULL CHECK (price > 0)
);
```

The order doesn't matter. It does not necessarily determine in which order the constraints are checked.

The `NOT NULL` constraint has an inverse: the `NULL` constraint. This does not mean that the column must be null, which would surely be useless. Instead, this simply selects the default behavior that the column might be null. The `NULL` constraint is not present in the SQL standard and should not be used in portable applications. (It was only added to PostgreSQL to be compatible with some other database systems.) Some users, however, like it because it makes it easy to toggle the constraint in a script file. For example, you could start with:

```
CREATE TABLE products (
    product_no integer NULL,
    name text NULL,
    price numeric NULL
);
```

and then insert the `NOT` key word where desired.

**Tip:** In most database designs the majority of columns should be marked not null.

### 5.3.3. Unique Constraints

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all the rows in the table. The syntax is:

```
CREATE TABLE products (
    product_no integer UNIQUE,
    name text,
    price numeric
);
```

when written as a column constraint, and:

```
CREATE TABLE products (
    product_no integer,
    name text,
    price numeric,
    UNIQUE (product_no)
);
```

when written as a table constraint.

If a unique constraint refers to a group of columns, the columns are listed separated by commas:

```
CREATE TABLE example (
    a integer,
    b integer,
    c integer,
    UNIQUE (a, c)
);
```

This specifies that the combination of values in the indicated columns is unique across the whole table, though any one of the columns need not be (and ordinarily isn't) unique.

You can assign your own name for a unique constraint, in the usual way:

```
CREATE TABLE products (
    product_no integer CONSTRAINT must_be_different UNIQUE,
    name text,
    price numeric
);
```

In general, a unique constraint is violated when there are two or more rows in the table where the values of all of the columns included in the constraint are equal. However, two null values are not considered equal in this comparison. That means even in the presence of a unique constraint it is possible to store duplicate rows that contain a null value in at least one of the constrained columns. This behavior conforms to the SQL standard, but we have heard that other SQL databases might not follow this rule. So be careful when developing applications that are intended to be portable.

### 5.3.4. Primary Keys

Technically, a primary key constraint is simply a combination of a unique constraint and a not-null constraint. So, the following two table definitions accept the same data:

```
CREATE TABLE products (
    product_no integer UNIQUE NOT NULL,
    name text,
    price numeric
);
```

```
CREATE TABLE products (
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);
```

Primary keys can also constrain more than one column; the syntax is similar to unique constraints:

```
CREATE TABLE example (
    a integer,
    b integer,
    c integer,
    PRIMARY KEY (a, c)
);
```

A primary key indicates that a column or group of columns can be used as a unique identifier for rows in the table. (This is a direct consequence of the definition of a primary key. Note that a unique constraint does not, by itself, provide a unique identifier because it does not exclude null values.) This is useful

both for documentation purposes and for client applications. For example, a GUI application that allows modifying row values probably needs to know the primary key of a table to be able to identify rows uniquely.

A table can have at most one primary key. (There can be any number of unique and not-null constraints, which are functionally the same thing, but only one can be identified as the primary key.) Relational database theory dictates that every table must have a primary key. This rule is not enforced by PostgreSQL, but it is usually best to follow it.

### 5.3.5. Foreign Keys

A foreign key constraint specifies that the values in a column (or a group of columns) must match the values appearing in some row of another table. We say this maintains the *referential integrity* between two related tables.

Say you have the product table that we have used several times already:

```
CREATE TABLE products (
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);
```

Let's also assume you have a table storing orders of those products. We want to ensure that the orders table only contains orders of products that actually exist. So we define a foreign key constraint in the orders table that references the products table:

```
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer REFERENCES products (product_no),
    quantity integer
);
```

Now it is impossible to create orders with `product_no` entries that do not appear in the products table.

We say that in this situation the orders table is the *referencing* table and the products table is the *referenced* table. Similarly, there are referencing and referenced columns.

You can also shorten the above command to:

```
CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    product_no integer REFERENCES products,
    quantity integer
);
```

because in absence of a column list the primary key of the referenced table is used as the referenced column(s).

A foreign key can also constrain and reference a group of columns. As usual, it then needs to be written in table constraint form. Here is a contrived syntax example:

```
CREATE TABLE t1 (
```

```

a integer PRIMARY KEY,
b integer,
c integer,
FOREIGN KEY (b, c) REFERENCES other_table (c1, c2)
);

```

Of course, the number and type of the constrained columns need to match the number and type of the referenced columns.

You can assign your own name for a foreign key constraint, in the usual way.

A table can contain more than one foreign key constraint. This is used to implement many-to-many relationships between tables. Say you have tables about products and orders, but now you want to allow one order to contain possibly many products (which the structure above did not allow). You could use this table structure:

```

CREATE TABLE products (
    product_no integer PRIMARY KEY,
    name text,
    price numeric
);

CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    shipping_address text,
    ...
);

CREATE TABLE order_items (
    product_no integer REFERENCES products,
    order_id integer REFERENCES orders,
    quantity integer,
    PRIMARY KEY (product_no, order_id)
);

```

Notice that the primary key overlaps with the foreign keys in the last table.

We know that the foreign keys disallow creation of orders that do not relate to any products. But what if a product is removed after an order is created that references it? SQL allows you to handle that as well. Intuitively, we have a few options:

- Disallow deleting a referenced product
- Delete the orders as well
- Something else?

To illustrate this, let's implement the following policy on the many-to-many relationship example above: when someone wants to remove a product that is still referenced by an order (via `order_items`), we disallow it. If someone removes an order, the order items are removed as well:

```

CREATE TABLE products (
    product_no integer PRIMARY KEY,
    name text,

```

```

        price numeric
    );

CREATE TABLE orders (
    order_id integer PRIMARY KEY,
    shipping_address text,
    ...
);

CREATE TABLE order_items (
    product_no integer REFERENCES products ON DELETE RESTRICT,
    order_id integer REFERENCES orders ON DELETE CASCADE,
    quantity integer,
    PRIMARY KEY (product_no, order_id)
);

```

Restricting and cascading deletes are the two most common options. `RESTRICT` prevents deletion of a referenced row. `NO ACTION` means that if any referencing rows still exist when the constraint is checked, an error is raised; this is the default behavior if you do not specify anything. (The essential difference between these two choices is that `NO ACTION` allows the check to be deferred until later in the transaction, whereas `RESTRICT` does not.) `CASCADE` specifies that when a referenced row is deleted, row(s) referencing it should be automatically deleted as well. There are two other options: `SET NULL` and `SET DEFAULT`. These cause the referencing columns to be set to nulls or default values, respectively, when the referenced row is deleted. Note that these do not excuse you from observing any constraints. For example, if an action specifies `SET DEFAULT` but the default value would not satisfy the foreign key, the operation will fail.

Analogous to `ON DELETE` there is also `ON UPDATE` which is invoked when a referenced column is changed (updated). The possible actions are the same.

More information about updating and deleting data is in Chapter 6.

Finally, we should mention that a foreign key must reference columns that either are a primary key or form a unique constraint. If the foreign key references a unique constraint, there are some additional possibilities regarding how null values are matched. These are explained in the reference documentation for `CREATE TABLE`.

## 5.4. System Columns

Every table has several *system columns* that are implicitly defined by the system. Therefore, these names cannot be used as names of user-defined columns. (Note that these restrictions are separate from whether the name is a key word or not; quoting a name will not allow you to escape these restrictions.) You do not really need to be concerned about these columns, just know they exist.

`oid`

The object identifier (object ID) of a row. This column is only present if the table was created using `WITH OIDS`, or if the `default_with_oids` configuration variable was set at the time. This column is of type `oid` (same name as the column); see Section 8.16 for more information about the type.

`tableoid`

The OID of the table containing this row. This column is particularly handy for queries that select from inheritance hierarchies (see Section 5.8), since without it, it's difficult to tell which individual table a row came from. The `tableoid` can be joined against the `oid` column of `pg_class` to obtain the table name.

`xmin`

The identity (transaction ID) of the inserting transaction for this row version. (A row version is an individual state of a row; each update of a row creates a new row version for the same logical row.)

`cmin`

The command identifier (starting at zero) within the inserting transaction.

`xmax`

The identity (transaction ID) of the deleting transaction, or zero for an undeleted row version. It is possible for this column to be nonzero in a visible row version. That usually indicates that the deleting transaction hasn't committed yet, or that an attempted deletion was rolled back.

`cmax`

The command identifier within the deleting transaction, or zero.

`ctid`

The physical location of the row version within its table. Note that although the `ctid` can be used to locate the row version very quickly, a row's `ctid` will change if it is updated or moved by `VACUUM FULL`. Therefore `ctid` is useless as a long-term row identifier. The OID, or even better a user-defined serial number, should be used to identify logical rows.

OIDs are 32-bit quantities and are assigned from a single cluster-wide counter. In a large or long-lived database, it is possible for the counter to wrap around. Hence, it is bad practice to assume that OIDs are unique, unless you take steps to ensure that this is the case. If you need to identify the rows in a table, using a sequence generator is strongly recommended. However, OIDs can be used as well, provided that a few additional precautions are taken:

- A unique constraint should be created on the OID column of each table for which the OID will be used to identify rows. When such a unique constraint (or unique index) exists, the system takes care not to generate an OID matching an already-existing row. (Of course, this is only possible if the table contains fewer than  $2^{32}$  (4 billion) rows, and in practice the table size had better be much less than that, or performance might suffer.)
- OIDs should never be assumed to be unique across tables; use the combination of `tableoid` and row OID if you need a database-wide identifier.
- Of course, the tables in question must be created `WITH OIDS`. As of PostgreSQL 8.1, `WITHOUT OIDS` is the default.

Transaction identifiers are also 32-bit quantities. In a long-lived database it is possible for transaction IDs to wrap around. This is not a fatal problem given appropriate maintenance procedures; see Chapter 23 for details. It is unwise, however, to depend on the uniqueness of transaction IDs over the long term (more than one billion transactions).

Command identifiers are also 32-bit quantities. This creates a hard limit of  $2^{32}$  (4 billion) SQL commands within a single transaction. In practice this limit is not a problem — note that the limit is on number of SQL commands, not number of rows processed. Also, as of PostgreSQL 8.3, only commands that actually modify the database contents will consume a command identifier.

## 5.5. Modifying Tables

When you create a table and you realize that you made a mistake, or the requirements of the application change, then you can drop the table and create it again. But this is not a convenient option if the table is already filled with data, or if the table is referenced by other database objects (for instance a foreign key constraint). Therefore PostgreSQL provides a family of commands to make modifications to existing tables. Note that this is conceptually distinct from altering the data contained in the table: here we are interested in altering the definition, or structure, of the table.

You can

- Add columns,
- Remove columns,
- Add constraints,
- Remove constraints,
- Change default values,
- Change column data types,
- Rename columns,
- Rename tables.

All these actions are performed using the *ALTER TABLE* command, whose reference page contains details beyond those given here.

### 5.5.1. Adding a Column

To add a column, use a command like this:

```
ALTER TABLE products ADD COLUMN description text;
```

The new column is initially filled with whatever default value is given (null if you don't specify a *DEFAULT* clause).

You can also define constraints on the column at the same time, using the usual syntax:

```
ALTER TABLE products ADD COLUMN description text CHECK (description <> "");
```

In fact all the options that can be applied to a column description in *CREATE TABLE* can be used here. Keep in mind however that the default value must satisfy the given constraints, or the *ADD* will fail. Alternatively, you can add constraints later (see below) after you've filled in the new column correctly.

**Tip:** Adding a column with a default requires updating each row of the table (to store the new column value). However, if no default is specified, PostgreSQL is able to avoid the physical update. So if you intend to fill the column with mostly nondefault values, it's best to add the column with no default, insert the correct values using *UPDATE*, and then add any desired default as described below.

### 5.5.2. Removing a Column

To remove a column, use a command like this:

```
ALTER TABLE products DROP COLUMN description;
```

Whatever data was in the column disappears. Table constraints involving the column are dropped, too. However, if the column is referenced by a foreign key constraint of another table, PostgreSQL will not silently drop that constraint. You can authorize dropping everything that depends on the column by adding `CASCADE`:

```
ALTER TABLE products DROP COLUMN description CASCADE;
```

See Section 5.11 for a description of the general mechanism behind this.

### 5.5.3. Adding a Constraint

To add a constraint, the table constraint syntax is used. For example:

```
ALTER TABLE products ADD CHECK (name <> "");
ALTER TABLE products ADD CONSTRAINT some_name UNIQUE (product_no);
ALTER TABLE products ADD FOREIGN KEY (product_group_id) REFERENCES product_groups;
```

To add a not-null constraint, which cannot be written as a table constraint, use this syntax:

```
ALTER TABLE products ALTER COLUMN product_no SET NOT NULL;
```

The constraint will be checked immediately, so the table data must satisfy the constraint before it can be added.

### 5.5.4. Removing a Constraint

To remove a constraint you need to know its name. If you gave it a name then that's easy. Otherwise the system assigned a generated name, which you need to find out. The `psql` command `\d tablename` can be helpful here; other interfaces might also provide a way to inspect table details. Then the command is:

```
ALTER TABLE products DROP CONSTRAINT some_name;
```

(If you are dealing with a generated constraint name like `$2`, don't forget that you'll need to double-quote it to make it a valid identifier.)

As with dropping a column, you need to add `CASCADE` if you want to drop a constraint that something else depends on. An example is that a foreign key constraint depends on a unique or primary key constraint on the referenced column(s).

This works the same for all constraint types except not-null constraints. To drop a not null constraint use:

```
ALTER TABLE products ALTER COLUMN product_no DROP NOT NULL;
```

(Recall that not-null constraints do not have names.)

### 5.5.5. Changing a Column's Default Value

To set a new default for a column, use a command like this:

```
ALTER TABLE products ALTER COLUMN price SET DEFAULT 7.77;
```

Note that this doesn't affect any existing rows in the table, it just changes the default for future `INSERT` commands.

To remove any default value, use:

```
ALTER TABLE products ALTER COLUMN price DROP DEFAULT;
```

This is effectively the same as setting the default to null. As a consequence, it is not an error to drop a default where one hadn't been defined, because the default is implicitly the null value.

### 5.5.6. Changing a Column's Data Type

To convert a column to a different data type, use a command like this:

```
ALTER TABLE products ALTER COLUMN price TYPE numeric(10,2);
```

This will succeed only if each existing entry in the column can be converted to the new type by an implicit cast. If a more complex conversion is needed, you can add a `USING` clause that specifies how to compute the new values from the old.

PostgreSQL will attempt to convert the column's default value (if any) to the new type, as well as any constraints that involve the column. But these conversions might fail, or might produce surprising results. It's often best to drop any constraints on the column before altering its type, and then add back suitably modified constraints afterwards.

### 5.5.7. Renaming a Column

To rename a column:

```
ALTER TABLE products RENAME COLUMN product_no TO product_number;
```

### 5.5.8. Renaming a Table

To rename a table:

```
ALTER TABLE products RENAME TO items;
```

## 5.6. Privileges

When you create a database object, you become its owner. By default, only the owner of an object can do anything with the object. In order to allow other users to use it, *privileges* must be granted. (However, users that have the superuser attribute can always access any object.)

There are several different privileges: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REFERENCES`, `TRIGGER`, `CREATE`, `CONNECT`, `TEMPORARY`, `EXECUTE`, and `USAGE`. The privileges applicable to a particular object vary depending on the object's type (table, function, etc). For complete information on the different types of privileges supported by PostgreSQL, refer to the *GRANT* reference page. The following sections and chapters will also show you how those privileges are used.

The right to modify or destroy an object is always the privilege of the owner only.

**Note:** To change the owner of a table, index, sequence, or view, use the *ALTER TABLE* command. There are corresponding *ALTER* commands for other object types.

To assign privileges, the `GRANT` command is used. For example, if `joe` is an existing user, and `accounts` is an existing table, the privilege to update the table can be granted with:

```
GRANT UPDATE ON accounts TO joe;
```

Writing `ALL` in place of a specific privilege grants all privileges that are relevant for the object type.

The special “user” name `PUBLIC` can be used to grant a privilege to every user on the system. Also, “group” roles can be set up to help manage privileges when there are many users of a database — for details see Chapter 19.

To revoke a privilege, use the fittingly named `REVOKE` command:

```
REVOKE ALL ON accounts FROM PUBLIC;
```

The special privileges of the object owner (i.e., the right to do `DROP`, `GRANT`, `REVOKE`, etc.) are always implicit in being the owner, and cannot be granted or revoked. But the object owner can choose to revoke his own ordinary privileges, for example to make a table read-only for himself as well as others.

Ordinarily, only the object's owner (or a superuser) can grant or revoke privileges on an object. However, it is possible to grant a privilege “with grant option”, which gives the recipient the right to grant it in turn to others. If the grant option is subsequently revoked then all who received the privilege from that recipient (directly or through a chain of grants) will lose the privilege. For details see the *GRANT* and *REVOKE* reference pages.

## 5.7. Schemas

A PostgreSQL database cluster contains one or more named databases. Users and groups of users are shared across the entire cluster, but no other data is shared across databases. Any given client connection to the server can access only the data in a single database, the one specified in the connection request.

**Note:** Users of a cluster do not necessarily have the privilege to access every database in the cluster. Sharing of user names means that there cannot be different users named, say, `joe` in two databases in the same cluster; but the system can be configured to allow `joe` access to only some of the databases.

A database contains one or more named *schemas*, which in turn contain tables. Schemas also contain other kinds of named objects, including data types, functions, and operators. The same object name can be used in different schemas without conflict; for example, both `schema1` and `myschema` can contain tables named `mytable`. Unlike databases, schemas are not rigidly separated: a user can access objects in any of the schemas in the database he is connected to, if he has privileges to do so.

There are several reasons why one might want to use schemas:

- To allow many users to use one database without interfering with each other.
- To organize database objects into logical groups to make them more manageable.
- Third-party applications can be put into separate schemas so they cannot collide with the names of other objects.

Schemas are analogous to directories at the operating system level, except that schemas cannot be nested.

### 5.7.1. Creating a Schema

To create a schema, use the `CREATE SCHEMA` command. Give the schema a name of your choice. For example:

```
CREATE SCHEMA myschema;
```

To create or access objects in a schema, write a *qualified name* consisting of the schema name and table name separated by a dot:

```
schema.table
```

This works anywhere a table name is expected, including the table modification commands and the data access commands discussed in the following chapters. (For brevity we will speak of tables only, but the same ideas apply to other kinds of named objects, such as types and functions.)

Actually, the even more general syntax

```
database.schema.table
```

can be used too, but at present this is just for *pro forma* compliance with the SQL standard. If you write a database name, it must be the same as the database you are connected to.

So to create a table in the new schema, use:

```
CREATE TABLE myschema.mytable (
    ...
);
```

To drop a schema if it's empty (all objects in it have been dropped), use:

```
DROP SCHEMA myschema;
```

To drop a schema including all contained objects, use:

```
DROP SCHEMA myschema CASCADE;
```

See Section 5.11 for a description of the general mechanism behind this.

Often you will want to create a schema owned by someone else (since this is one of the ways to restrict the activities of your users to well-defined namespaces). The syntax for that is:

```
CREATE SCHEMA schemaname AUTHORIZATION username;
```

You can even omit the schema name, in which case the schema name will be the same as the user name. See Section 5.7.6 for how this can be useful.

Schema names beginning with `pg_` are reserved for system purposes and cannot be created by users.

## 5.7.2. The Public Schema

In the previous sections we created tables without specifying any schema names. By default, such tables (and other objects) are automatically put into a schema named “public”. Every new database contains such a schema. Thus, the following are equivalent:

```
CREATE TABLE products ( ... );
```

and:

```
CREATE TABLE public.products ( ... );
```

## 5.7.3. The Schema Search Path

Qualified names are tedious to write, and it's often best not to wire a particular schema name into applications anyway. Therefore tables are often referred to by *unqualified names*, which consist of just the table name. The system determines which table is meant by following a *search path*, which is a list of schemas to look in. The first matching table in the search path is taken to be the one wanted. If there is no match in the search path, an error is reported, even if matching table names exist in other schemas in the database.

The first schema named in the search path is called the current schema. Aside from being the first schema searched, it is also the schema in which new tables will be created if the `CREATE TABLE` command does not specify a schema name.

To show the current search path, use the following command:

```
SHOW search_path;
```

In the default setup this returns:

```
search_path
-----
"$user",public
```

The first element specifies that a schema with the same name as the current user is to be searched. If no such schema exists, the entry is ignored. The second element refers to the public schema that we have seen already.

The first schema in the search path that exists is the default location for creating new objects. That is the reason that by default objects are created in the public schema. When objects are referenced in any other context without schema qualification (table modification, data modification, or query commands) the search path is traversed until a matching object is found. Therefore, in the default configuration, any unqualified access again can only refer to the public schema.

To put our new schema in the path, we use:

```
SET search_path TO myschema,public;
```

(We omit the `$user` here because we have no immediate need for it.) And then we can access the table without schema qualification:

```
DROP TABLE mytable;
```

Also, since `myschema` is the first element in the path, new objects would by default be created in it.

We could also have written:

```
SET search_path TO myschema;
```

Then we no longer have access to the public schema without explicit qualification. There is nothing special about the public schema except that it exists by default. It can be dropped, too.

See also Section 9.22 for other ways to manipulate the schema search path.

The search path works in the same way for data type names, function names, and operator names as it does for table names. Data type and function names can be qualified in exactly the same way as table names. If you need to write a qualified operator name in an expression, there is a special provision: you must write

```
OPERATOR(schema.operator)
```

This is needed to avoid syntactic ambiguity. An example is:

```
SELECT 3 OPERATOR(pg_catalog.+) 4;
```

In practice one usually relies on the search path for operators, so as not to have to write anything so ugly as that.

### 5.7.4. Schemas and Privileges

By default, users cannot access any objects in schemas they do not own. To allow that, the owner of the schema needs to grant the `USAGE` privilege on the schema. To allow users to make use of the objects in the schema, additional privileges might need to be granted, as appropriate for the object.

A user can also be allowed to create objects in someone else's schema. To allow that, the `CREATE` privilege on the schema needs to be granted. Note that by default, everyone has `CREATE` and `USAGE` privileges on the schema `public`. This allows all users that are able to connect to a given database to create objects in its `public` schema. If you do not want to allow that, you can revoke that privilege:

```
REVOKE CREATE ON SCHEMA public FROM PUBLIC;
```

(The first “public” is the schema, the second “public” means “every user”. In the first sense it is an identifier, in the second sense it is a key word, hence the different capitalization; recall the guidelines from Section 4.1.1.)

### 5.7.5. The System Catalog Schema

In addition to `public` and user-created schemas, each database contains a `pg_catalog` schema, which contains the system tables and all the built-in data types, functions, and operators. `pg_catalog` is always effectively part of the search path. If it is not named explicitly in the path then it is implicitly searched *before* searching the path's schemas. This ensures that built-in names will always be findable. However, you can explicitly place `pg_catalog` at the end of your search path if you prefer to have user-defined names override built-in names.

In PostgreSQL versions before 7.3, table names beginning with `pg_` were reserved. This is no longer true: you can create such a table name if you wish, in any non-system schema. However, it's best to continue to avoid such names, to ensure that you won't suffer a conflict if some future version defines a system table named the same as your table. (With the default search path, an unqualified reference to your table name would be resolved as the system table instead.) System tables will continue to follow the convention of having names beginning with `pg_`, so that they will not conflict with unqualified user-table names so long as users avoid the `pg_` prefix.

### 5.7.6. Usage Patterns

Schemas can be used to organize your data in many ways. There are a few usage patterns that are recommended and are easily supported by the default configuration:

- If you do not create any schemas then all users access the `public` schema implicitly. This simulates the situation where schemas are not available at all. This setup is mainly recommended when there is only a single user or a few cooperating users in a database. This setup also allows smooth transition from the non-schema-aware world.

- You can create a schema for each user with the same name as that user. Recall that the default search path starts with `$user`, which resolves to the user name. Therefore, if each user has a separate schema, they access their own schemas by default.

If you use this setup then you might also want to revoke access to the `public` schema (or drop it altogether), so users are truly constrained to their own schemas.

- To install shared applications (tables to be used by everyone, additional functions provided by third parties, etc.), put them into separate schemas. Remember to grant appropriate privileges to allow the other users to access them. Users can then refer to these additional objects by qualifying the names with a schema name, or they can put the additional schemas into their search path, as they choose.

### 5.7.7. Portability

In the SQL standard, the notion of objects in the same schema being owned by different users does not exist. Moreover, some implementations do not allow you to create schemas that have a different name than their owner. In fact, the concepts of schema and user are nearly equivalent in a database system that implements only the basic schema support specified in the standard. Therefore, many users consider qualified names to really consist of `username.tablename`. This is how PostgreSQL will effectively behave if you create a per-user schema for every user.

Also, there is no concept of a `public` schema in the SQL standard. For maximum conformance to the standard, you should not use (perhaps even remove) the `public` schema.

Of course, some SQL database systems might not implement schemas at all, or provide namespace support by allowing (possibly limited) cross-database access. If you need to work with those systems, then maximum portability would be achieved by not using schemas at all.

## 5.8. Inheritance

PostgreSQL implements table inheritance, which can be a useful tool for database designers. (SQL:1999 and later define a type inheritance feature, which differs in many respects from the features described here.)

Let's start with an example: suppose we are trying to build a data model for cities. Each state has many cities, but only one capital. We want to be able to quickly retrieve the capital city for any particular state. This can be done by creating two tables, one for state capitals and one for cities that are not capitals. However, what happens when we want to ask for data about a city, regardless of whether it is a capital or not? The inheritance feature can help to resolve this problem. We define the `capitals` table so that it inherits from `cities`:

```
CREATE TABLE cities (
    name          text,
    population     float,
    altitude       int    -- in feet
);
```

```
CREATE TABLE capitals (
    state          char(2)
) INHERITS (cities);
```

In this case, the `capitals` table *inherits* all the columns of its parent table, `cities`. State capitals also have an extra column, `state`, that shows their state.

In PostgreSQL, a table can inherit from zero or more other tables, and a query can reference either all rows of a table or all rows of a table plus all of its descendant tables. The latter behavior is the default. For example, the following query finds the names of all cities, including state capitals, that are located at an altitude over 500 feet:

```
SELECT name, altitude
FROM cities
WHERE altitude > 500;
```

Given the sample data from the PostgreSQL tutorial (see Section 2.1), this returns:

name		altitude
Las Vegas		2174
Mariposa		1953
Madison		845

On the other hand, the following query finds all the cities that are not state capitals and are situated at an altitude over 500 feet:

```
SELECT name, altitude
FROM ONLY cities
WHERE altitude > 500;
```

name		altitude
Las Vegas		2174
Mariposa		1953

Here the `ONLY` keyword indicates that the query should apply only to `cities`, and not any tables below `cities` in the inheritance hierarchy. Many of the commands that we have already discussed — `SELECT`, `UPDATE` and `DELETE` — support the `ONLY` keyword.

In some cases you might wish to know which table a particular row originated from. There is a system column called `tableoid` in each table which can tell you the originating table:

```
SELECT c.tableoid, c.name, c.altitude
FROM cities c
WHERE c.altitude > 500;
```

which returns:

tableoid		name		altitude
----------	--	------	--	----------

```

139793 | Las Vegas |      2174
139793 | Mariposa  |      1953
139798 | Madison   |       845

```

(If you try to reproduce this example, you will probably get different numeric OIDs.) By doing a join with `pg_class` you can see the actual table names:

```

SELECT p.relname, c.name, c.altitude
FROM cities c, pg_class p
WHERE c.altitude > 500 and c.tableoid = p.oid;

```

which returns:

```

relname | name      | altitude
-----+-----+-----
cities  | Las Vegas |      2174
cities  | Mariposa  |      1953
capitals | Madison   |       845

```

Inheritance does not automatically propagate data from `INSERT` or `COPY` commands to other tables in the inheritance hierarchy. In our example, the following `INSERT` statement will fail:

```

INSERT INTO cities (name, population, altitude, state)
VALUES ('New York', NULL, NULL, 'NY');

```

We might hope that the data would somehow be routed to the `capitals` table, but this does not happen: `INSERT` always inserts into exactly the table specified. In some cases it is possible to redirect the insertion using a rule (see Chapter 36). However that does not help for the above case because the `cities` table does not contain the column `state`, and so the command will be rejected before the rule can be applied.

All check constraints and not-null constraints on a parent table are automatically inherited by its children. Other types of constraints (unique, primary key, and foreign key constraints) are not inherited.

A table can inherit from more than one parent table, in which case it has the union of the columns defined by the parent tables. Any columns declared in the child table's definition are added to these. If the same column name appears in multiple parent tables, or in both a parent table and the child's definition, then these columns are “merged” so that there is only one such column in the child table. To be merged, columns must have the same data types, else an error is raised. The merged column will have copies of all the check constraints coming from any one of the column definitions it came from, and will be marked not-null if any of them are.

Table inheritance is typically established when the child table is created, using the `INHERITS` clause of the `CREATE TABLE` statement. Alternatively, a table which is already defined in a compatible way can have a new parent relationship added, using the `INHERIT` variant of `ALTER TABLE`. To do this the new child table must already include columns with the same names and types as the columns of the parent. It must also include check constraints with the same names and check expressions as those of the parent. Similarly an inheritance link can be removed from a child using the `NO INHERIT` variant of `ALTER TABLE`. Dynamically adding and removing inheritance links like this can be useful when the inheritance relationship is being used for table partitioning (see Section 5.9).

One convenient way to create a compatible table that will later be made a new child is to use the `LIKE` clause in `CREATE TABLE`. This creates a new table with the same columns as the source table. If there are

any `CHECK` constraints defined on the source table, the `INCLUDING CONSTRAINTS` option to `LIKE` should be specified, as the new child must have constraints matching the parent to be considered compatible.

A parent table cannot be dropped while any of its children remain. Neither can columns of child tables be dropped or altered if they are inherited from any parent tables. If you wish to remove a table and all of its descendants, one easy way is to drop the parent table with the `CASCADE` option.

`ALTER TABLE` will propagate any changes in column data definitions and check constraints down the inheritance hierarchy. Again, dropping columns or constraints on parent tables is only possible when using the `CASCADE` option. `ALTER TABLE` follows the same rules for duplicate column merging and rejection that apply during `CREATE TABLE`.

### 5.8.1. Caveats

Table access permissions are not automatically inherited. Therefore, a user attempting to access a parent table must either have permissions to do the operation on all its child tables as well, or must use the `ONLY` notation. When adding a new child table to an existing inheritance hierarchy, be careful to grant all the needed permissions on it.

A serious limitation of the inheritance feature is that indexes (including unique constraints) and foreign key constraints only apply to single tables, not to their inheritance children. This is true on both the referencing and referenced sides of a foreign key constraint. Thus, in the terms of the above example:

- If we declared `cities.name` to be `UNIQUE` or a `PRIMARY KEY`, this would not stop the `capitals` table from having rows with names duplicating rows in `cities`. And those duplicate rows would by default show up in queries from `cities`. In fact, by default `capitals` would have no unique constraint at all, and so could contain multiple rows with the same name. You could add a unique constraint to `capitals`, but this would not prevent duplication compared to `cities`.
- Similarly, if we were to specify that `cities.name` `REFERENCES` some other table, this constraint would not automatically propagate to `capitals`. In this case you could work around it by manually adding the same `REFERENCES` constraint to `capitals`.
- Specifying that another table's column `REFERENCES cities(name)` would allow the other table to contain city names, but not capital names. There is no good workaround for this case.

These deficiencies will probably be fixed in some future release, but in the meantime considerable care is needed in deciding whether inheritance is useful for your problem.

**Deprecated:** In releases of PostgreSQL prior to 7.1, the default behavior was not to include child tables in queries. This was found to be error prone and also in violation of the SQL standard. You can get the pre-7.1 behavior by turning off the `sql_inheritance` configuration option.

## 5.9. Partitioning

PostgreSQL supports basic table partitioning. This section describes why and how to implement partitioning as part of your database design.

### 5.9.1. Overview

Partitioning refers to splitting what is logically one large table into smaller physical pieces. Partitioning can provide several benefits:

- Query performance can be improved dramatically in certain situations, particularly when most of the heavily accessed rows of the table are in a single partition or a small number of partitions. The partitioning substitutes for leading columns of indexes, reducing index size and making it more likely that the heavily-used parts of the indexes fit in memory.
- When queries or updates access a large percentage of a single partition, performance can be improved by taking advantage of sequential scan of that partition instead of using an index and random access reads scattered across the whole table.
- Bulk loads and deletes can be accomplished by adding or removing partitions, if that requirement is planned into the partitioning design. `ALTER TABLE` is far faster than a bulk operation. It also entirely avoids the `VACUUM` overhead caused by a bulk `DELETE`.
- Seldom-used data can be migrated to cheaper and slower storage media.

The benefits will normally be worthwhile only when a table would otherwise be very large. The exact point at which a table will benefit from partitioning depends on the application, although a rule of thumb is that the size of the table should exceed the physical memory of the database server.

Currently, PostgreSQL supports partitioning via table inheritance. Each partition must be created as a child table of a single parent table. The parent table itself is normally empty; it exists just to represent the entire data set. You should be familiar with inheritance (see Section 5.8) before attempting to set up partitioning.

The following forms of partitioning can be implemented in PostgreSQL:

#### Range Partitioning

The table is partitioned into “ranges” defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. For example one might partition by date ranges, or by ranges of identifiers for particular business objects.

#### List Partitioning

The table is partitioned by explicitly listing which key values appear in each partition.

### 5.9.2. Implementing Partitioning

To set up a partitioned table, do the following:

1. Create the “master” table, from which all of the partitions will inherit.

This table will contain no data. Do not define any check constraints on this table, unless you intend them to be applied equally to all partitions. There is no point in defining any indexes or unique constraints on it, either.

2. Create several “child” tables that each inherit from the master table. Normally, these tables will not add any columns to the set inherited from the master.

We will refer to the child tables as partitions, though they are in every way normal PostgreSQL tables.

3. Add table constraints to the partition tables to define the allowed key values in each partition.

Typical examples would be:

```
CHECK ( x = 1 )
CHECK ( county IN ( 'Oxfordshire', 'Buckinghamshire', 'Warwickshire' ))
CHECK ( outletID >= 100 AND outletID < 200 )
```

Ensure that the constraints guarantee that there is no overlap between the key values permitted in different partitions. A common mistake is to set up range constraints like this:

```
CHECK ( outletID BETWEEN 100 AND 200 )
CHECK ( outletID BETWEEN 200 AND 300 )
```

This is wrong since it is not clear which partition the key value 200 belongs in.

Note that there is no difference in syntax between range and list partitioning; those terms are descriptive only.

4. For each partition, create an index on the key column(s), as well as any other indexes you might want. (The key index is not strictly necessary, but in most scenarios it is helpful. If you intend the key values to be unique then you should always create a unique or primary-key constraint for each partition.)
5. Optionally, define a trigger or rule to redirect data inserted into the master table to the appropriate partition.
6. Ensure that the `constraint_exclusion` configuration parameter is enabled in `postgresql.conf`. Without this, queries will not be optimized as desired.

For example, suppose we are constructing a database for a large ice cream company. The company measures peak temperatures every day as well as ice cream sales in each region. Conceptually, we want a table like this:

```
CREATE TABLE measurement (
    city_id          int not null,
    logdate          date not null,
    peaktemp         int,
    unitsales        int
);
```

We know that most queries will access just the last week’s, month’s or quarter’s data, since the main use of this table will be to prepare online reports for management. To reduce the amount of old data that needs to be stored, we decide to only keep the most recent 3 years worth of data. At the beginning of each month we will remove the oldest month’s data.

In this situation we can use partitioning to help us meet all of our different requirements for the measurements table. Following the steps outlined above, partitioning can be set up as follows:

1. The master table is the `measurement` table, declared exactly as above.
2. Next we create one partition for each active month:

```
CREATE TABLE measurement_y2006m02 ( ) INHERITS (measurement);
CREATE TABLE measurement_y2006m03 ( ) INHERITS (measurement);
...
```

```
CREATE TABLE measurement_y2007m11 ( ) INHERITS (measurement);
CREATE TABLE measurement_y2007m12 ( ) INHERITS (measurement);
CREATE TABLE measurement_y2008m01 ( ) INHERITS (measurement);
```

Each of the partitions are complete tables in their own right, but they inherit their definitions from the `measurement` table.

This solves one of our problems: deleting old data. Each month, all we will need to do is perform a `DROP TABLE` on the oldest child table and create a new child table for the new month's data.

3. We must provide non-overlapping table constraints. Rather than just creating the partition tables as above, the table creation script should really be:

```
CREATE TABLE measurement_y2006m02 (
    CHECK ( logdate >= DATE '2006-02-01' AND logdate < DATE '2006-03-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2006m03 (
    CHECK ( logdate >= DATE '2006-03-01' AND logdate < DATE '2006-04-01' )
) INHERITS (measurement);
...
CREATE TABLE measurement_y2007m11 (
    CHECK ( logdate >= DATE '2007-11-01' AND logdate < DATE '2007-12-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2007m12 (
    CHECK ( logdate >= DATE '2007-12-01' AND logdate < DATE '2008-01-01' )
) INHERITS (measurement);
CREATE TABLE measurement_y2008m01 (
    CHECK ( logdate >= DATE '2008-01-01' AND logdate < DATE '2008-02-01' )
) INHERITS (measurement);
```

4. We probably need indexes on the key columns too:

```
CREATE INDEX measurement_y2006m02_logdate ON measurement_y2006m02 (logdate);
CREATE INDEX measurement_y2006m03_logdate ON measurement_y2006m03 (logdate);
...
CREATE INDEX measurement_y2007m11_logdate ON measurement_y2007m11 (logdate);
CREATE INDEX measurement_y2007m12_logdate ON measurement_y2007m12 (logdate);
CREATE INDEX measurement_y2008m01_logdate ON measurement_y2008m01 (logdate);
```

We choose not to add further indexes at this time.

5. We want our application to be able to say `INSERT INTO measurement ...` and have the data be redirected into the appropriate partition table. We can arrange that by attaching a suitable trigger function to the master table. If data will be added only to the latest partition, we can use a very simple trigger function:

```
CREATE OR REPLACE FUNCTION measurement_insert_trigger()
RETURNS TRIGGER AS $$
BEGIN
    INSERT INTO measurement_y2008m01 VALUES (NEW.*);
    RETURN NULL;
END;
$$
LANGUAGE plpgsql;
```

After creating the function, we create a trigger which calls the trigger function:

```
CREATE TRIGGER insert_measurement_trigger
BEFORE INSERT ON measurement
FOR EACH ROW EXECUTE PROCEDURE measurement_insert_trigger();
```

We must redefine the trigger function each month so that it always points to the current partition. The trigger definition does not need to be updated, however.

We might want to insert data and have the server automatically locate the partition into which the row should be added. We could do this with a more complex trigger function, for example:

```
CREATE OR REPLACE FUNCTION measurement_insert_trigger()
RETURNS TRIGGER AS $$
BEGIN
    IF ( NEW.logdate >= DATE '2006-02-01' AND NEW.logdate < DATE '2006-03-01' ) THEN
        INSERT INTO measurement_y2006m02 VALUES (NEW.*);
    ELSIF ( NEW.logdate >= DATE '2006-03-01' AND NEW.logdate < DATE '2006-04-01' ) THEN
        INSERT INTO measurement_y2006m03 VALUES (NEW.*);
    ...
    ELSIF ( NEW.logdate >= DATE '2008-01-01' AND NEW.logdate < DATE '2008-02-01' ) THEN
        INSERT INTO measurement_y2008m01 VALUES (NEW.*);
    ELSE
        RAISE EXCEPTION 'Date out of range. Fix the measurement_insert_trigger() function';
    END IF;
    RETURN NULL;
END;
$$
LANGUAGE plpgsql;
```

The trigger definition is the same as before. Note that each IF test must exactly match the CHECK constraint for its partition.

While this function is more complex than the single-month case, it doesn't need to be updated as often, since branches can be added in advance of being needed.

**Note:** In practice it might be best to check the newest partition first, if most inserts go into that partition. For simplicity we have shown the trigger's tests in the same order as in other parts of this example.

As we can see, a complex partitioning scheme could require a substantial amount of DDL. In the above example we would be creating a new partition each month, so it might be wise to write a script that generates the required DDL automatically.

### 5.9.3. Managing Partitions

Normally the set of partitions established when initially defining the table are not intended to remain static. It is common to want to remove old partitions of data and periodically add new partitions for new data. One of the most important advantages of partitioning is precisely that it allows this otherwise painful task to be executed nearly instantaneously by manipulating the partition structure, rather than physically moving large amounts of data around.

The simplest option for removing old data is simply to drop the partition that is no longer necessary:

```
DROP TABLE measurement_y2006m02;
```

This can very quickly delete millions of records because it doesn't have to individually delete every record.

Another option that is often preferable is to remove the partition from the partitioned table but retain access to it as a table in its own right:

```
ALTER TABLE measurement_y2006m02 NO INHERIT measurement;
```

This allows further operations to be performed on the data before it is dropped. For example, this is often a useful time to back up the data using `COPY`, `pg_dump`, or similar tools. It might also be a useful time to aggregate data into smaller formats, perform other data manipulations, or run reports.

Similarly we can add a new partition to handle new data. We can create an empty partition in the partitioned table just as the original partitions were created above:

```
CREATE TABLE measurement_y2008m02 (
    CHECK ( logdate >= DATE '2008-02-01' AND logdate < DATE '2008-03-01' )
) INHERITS (measurement);
```

As an alternative, it is sometimes more convenient to create the new table outside the partition structure, and make it a proper partition later. This allows the data to be loaded, checked, and transformed prior to it appearing in the partitioned table:

```
CREATE TABLE measurement_y2008m02
    (LIKE measurement INCLUDING DEFAULTS INCLUDING CONSTRAINTS);
ALTER TABLE measurement_y2008m02 ADD CONSTRAINT y2008m02
    CHECK ( logdate >= DATE '2008-02-01' AND logdate < DATE '2008-03-01' );
\copy measurement_y2008m02 from 'measurement_y2008m02'
-- possibly some other data preparation work
ALTER TABLE measurement_y2008m02 INHERIT measurement;
```

### 5.9.4. Partitioning and Constraint Exclusion

*Constraint exclusion* is a query optimization technique that improves performance for partitioned tables defined in the fashion described above. As an example:

```
SET constraint_exclusion = on;
SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';
```

Without constraint exclusion, the above query would scan each of the partitions of the `measurement` table. With constraint exclusion enabled, the planner will examine the constraints of each partition and try to prove that the partition need not be scanned because it could not contain any rows meeting the query's `WHERE` clause. When the planner can prove this, it excludes the partition from the query plan.

You can use the `EXPLAIN` command to show the difference between a plan with `constraint_exclusion` on and a plan with it off. A typical default plan for this type of table setup is:

```
SET constraint_exclusion = off;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';
```

## QUERY PLAN

```

-----
Aggregate  (cost=158.66..158.68 rows=1 width=0)
  -> Append  (cost=0.00..151.88 rows=2715 width=0)
    -> Seq Scan on measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)
    -> Seq Scan on measurement_y2006m02 measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)
    -> Seq Scan on measurement_y2006m03 measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)
    ...
    -> Seq Scan on measurement_y2007m12 measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)
    -> Seq Scan on measurement_y2008m01 measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)

```

Some or all of the partitions might use index scans instead of full-table sequential scans, but the point here is that there is no need to scan the older partitions at all to answer this query. When we enable constraint exclusion, we get a significantly reduced plan that will deliver the same answer:

```

SET constraint_exclusion = on;
EXPLAIN SELECT count(*) FROM measurement WHERE logdate >= DATE '2008-01-01';

```

## QUERY PLAN

```

-----
Aggregate  (cost=63.47..63.48 rows=1 width=0)
  -> Append  (cost=0.00..60.75 rows=1086 width=0)
    -> Seq Scan on measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)
    -> Seq Scan on measurement_y2008m01 measurement  (cost=0.00..30.38 rows=543 width=0)
        Filter: (logdate >= '2008-01-01'::date)

```

Note that constraint exclusion is driven only by `CHECK` constraints, not by the presence of indexes. Therefore it isn't necessary to define indexes on the key columns. Whether an index needs to be created for a given partition depends on whether you expect that queries that scan the partition will generally scan a large part of the partition or just a small part. An index will be helpful in the latter case but not the former.

## 5.9.5. Alternative Partitioning Methods

A different approach to redirecting inserts into the appropriate partition table is to set up rules, instead of a trigger, on the master table. For example:

```

CREATE RULE measurement_insert_y2006m02 AS
ON INSERT TO measurement WHERE
    ( logdate >= DATE '2006-02-01' AND logdate < DATE '2006-03-01' )
DO INSTEAD
    INSERT INTO measurement_y2006m02 VALUES (NEW.*);
...
CREATE RULE measurement_insert_y2008m01 AS
ON INSERT TO measurement WHERE
    ( logdate >= DATE '2008-01-01' AND logdate < DATE '2008-02-01' )

```

```
DO INSTEAD
    INSERT INTO measurement_y2008m01 VALUES (NEW.*);
```

A rule has significantly more overhead than a trigger, but the overhead is paid once per query rather than once per row, so this method might be advantageous for bulk-insert situations. In most cases, however, the trigger method will offer better performance.

Be aware that `COPY` ignores rules. If you want to use `COPY` to insert data, you'll need to copy into the correct partition table rather than into the master. `COPY` does fire triggers, so you can use it normally if you use the trigger approach.

Another disadvantage of the rule approach is that there is no simple way to force an error if the set of rules doesn't cover the insertion date; the data will silently go into the master table instead.

Partitioning can also be arranged using a `UNION ALL` view, instead of table inheritance. For example,

```
CREATE VIEW measurement AS
    SELECT * FROM measurement_y2006m02
UNION ALL SELECT * FROM measurement_y2006m03
...
UNION ALL SELECT * FROM measurement_y2007m11
UNION ALL SELECT * FROM measurement_y2007m12
UNION ALL SELECT * FROM measurement_y2008m01;
```

However, the need to recreate the view adds an extra step to adding and dropping individual partitions of the data set. In practice this method has little to recommend it compared to using inheritance.

## 5.9.6. Caveats

The following caveats apply to partitioned tables:

- There is no automatic way to verify that all of the `CHECK` constraints are mutually exclusive. It is safer to create code that generates partitions and creates and/or modifies associated objects than to write each by hand.
- The schemes shown here assume that the partition key column(s) of a row never change, or at least do not change enough to require it to move to another partition. An `UPDATE` that attempts to do that will fail because of the `CHECK` constraints. If you need to handle such cases, you can put suitable update triggers on the partition tables, but it makes management of the structure much more complicated.
- If you are using manual `VACUUM` or `ANALYZE` commands, don't forget that you need to run them on each partition individually. A command like

```
ANALYZE measurement;
```

will only process the master table.

The following caveats apply to constraint exclusion:

- Constraint exclusion only works when the query's `WHERE` clause contains constants. A parameterized query will not be optimized, since the planner cannot know which partitions the parameter value might select at run time. For the same reason, “stable” functions such as `CURRENT_DATE` must be avoided.
- Keep the partitioning constraints simple, else the planner may not be able to prove that partitions don't need to be visited. Use simple equality conditions for list partitioning, or simple range tests for range partitioning, as illustrated in the preceding examples. A good rule of thumb is that partitioning constraints should contain only comparisons of the partitioning column(s) to constants using B-tree-indexable operators.
- All constraints on all partitions of the master table are examined during constraint exclusion, so large numbers of partitions are likely to increase query planning time considerably. Partitioning using these techniques will work well with up to perhaps a hundred partitions; don't try to use many thousands of partitions.

## 5.10. Other Database Objects

Tables are the central objects in a relational database structure, because they hold your data. But they are not the only objects that exist in a database. Many other kinds of objects can be created to make the use and management of the data more efficient or convenient. They are not discussed in this chapter, but we give you a list here so that you are aware of what is possible.

- Views
- Functions and operators
- Data types and domains
- Triggers and rewrite rules

Detailed information on these topics appears in Part V.

## 5.11. Dependency Tracking

When you create complex database structures involving many tables with foreign key constraints, views, triggers, functions, etc. you will implicitly create a net of dependencies between the objects. For instance, a table with a foreign key constraint depends on the table it references.

To ensure the integrity of the entire database structure, PostgreSQL makes sure that you cannot drop objects that other objects still depend on. For example, attempting to drop the `products` table we had considered in Section 5.3.5, with the `orders` table depending on it, would result in an error message such as this:

```
DROP TABLE products;
```

```
NOTICE:  constraint orders_product_no_fkey on table orders depends on table products
ERROR:  cannot drop table products because other objects depend on it
```

HINT: Use `DROP ... CASCADE` to drop the dependent objects too.

The error message contains a useful hint: if you do not want to bother deleting all the dependent objects individually, you can run

```
DROP TABLE products CASCADE;
```

and all the dependent objects will be removed. In this case, it doesn't remove the orders table, it only removes the foreign key constraint. (If you want to check what `DROP ... CASCADE` will do, run `DROP` without `CASCADE` and read the `NOTICE` messages.)

All drop commands in PostgreSQL support specifying `CASCADE`. Of course, the nature of the possible dependencies varies with the type of the object. You can also write `RESTRICT` instead of `CASCADE` to get the default behavior, which is to prevent drops of objects that other objects depend on.

**Note:** According to the SQL standard, specifying either `RESTRICT` or `CASCADE` is required. No database system actually enforces that rule, but whether the default behavior is `RESTRICT` or `CASCADE` varies across systems.

**Note:** Foreign key constraint dependencies and serial column dependencies from PostgreSQL versions prior to 7.3 are *not* maintained or created during the upgrade process. All other dependency types will be properly created during an upgrade from a pre-7.3 database.

# Chapter 6. Data Manipulation

The previous chapter discussed how to create tables and other structures to hold your data. Now it is time to fill the tables with data. This chapter covers how to insert, update, and delete table data. We also introduce ways to effect automatic data changes when certain events occur: triggers and rewrite rules. The chapter after this will finally explain how to extract your long-lost data back out of the database.

## 6.1. Inserting Data

When a table is created, it contains no data. The first thing to do before a database can be of much use is to insert data. Data is conceptually inserted one row at a time. Of course you can also insert more than one row, but there is no way to insert less than one row at a time. Even if you know only some column values, a complete row must be created.

To create a new row, use the *INSERT* command. The command requires the table name and a value for each of the columns of the table. For example, consider the products table from Chapter 5:

```
CREATE TABLE products (  
    product_no integer,  
    name text,  
    price numeric  
);
```

An example command to insert a row would be:

```
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

The data values are listed in the order in which the columns appear in the table, separated by commas. Usually, the data values will be literals (constants), but scalar expressions are also allowed.

The above syntax has the drawback that you need to know the order of the columns in the table. To avoid that you can also list the columns explicitly. For example, both of the following commands have the same effect as the one above:

```
INSERT INTO products (product_no, name, price) VALUES (1, 'Cheese', 9.99);  
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

Many users consider it good practice to always list the column names.

If you don't have values for all the columns, you can omit some of them. In that case, the columns will be filled with their default values. For example:

```
INSERT INTO products (product_no, name) VALUES (1, 'Cheese');  
INSERT INTO products VALUES (1, 'Cheese');
```

The second form is a PostgreSQL extension. It fills the columns from the left with as many values as are given, and the rest will be defaulted.

For clarity, you can also request default values explicitly, for individual columns or for the entire row:

```
INSERT INTO products (product_no, name, price) VALUES (1, 'Cheese', DEFAULT);  
INSERT INTO products DEFAULT VALUES;
```

You can insert multiple rows in a single command:

```
INSERT INTO products (product_no, name, price) VALUES
(1, 'Cheese', 9.99),
(2, 'Bread', 1.99),
(3, 'Milk', 2.99);
```

**Tip:** When inserting a lot of data at the same time, considering using the *COPY* command. It is not as flexible as the *INSERT* command, but is more efficient. Refer to Section 14.4 for more information on improving bulk loading performance.

## 6.2. Updating Data

The modification of data that is already in the database is referred to as updating. You can update individual rows, all the rows in a table, or a subset of all rows. Each column can be updated separately; the other columns are not affected.

To perform an update, you need three pieces of information:

1. The name of the table and column to update,
2. The new value of the column,
3. Which row(s) to update.

Recall from Chapter 5 that SQL does not, in general, provide a unique identifier for rows. Therefore it is not necessarily possible to directly specify which row to update. Instead, you specify which conditions a row must meet in order to be updated. Only if you have a primary key in the table (no matter whether you declared it or not) can you reliably address individual rows, by choosing a condition that matches the primary key. Graphical database access tools rely on this fact to allow you to update rows individually.

For example, this command updates all products that have a price of 5 to have a price of 10:

```
UPDATE products SET price = 10 WHERE price = 5;
```

This might cause zero, one, or many rows to be updated. It is not an error to attempt an update that does not match any rows.

Let's look at that command in detail. First is the key word *UPDATE* followed by the table name. As usual, the table name can be schema-qualified, otherwise it is looked up in the path. Next is the key word *SET* followed by the column name, an equals sign and the new column value. The new column value can be any scalar expression, not just a constant. For example, if you want to raise the price of all products by 10% you could use:

```
UPDATE products SET price = price * 1.10;
```

As you see, the expression for the new value can refer to the existing value(s) in the row. We also left out the `WHERE` clause. If it is omitted, it means that all rows in the table are updated. If it is present, only those rows that match the `WHERE` condition are updated. Note that the equals sign in the `SET` clause is an assignment while the one in the `WHERE` clause is a comparison, but this does not create any ambiguity. Of course, the `WHERE` condition does not have to be an equality test. Many other operators are available (see Chapter 9). But the expression needs to evaluate to a Boolean result.

You can update more than one column in an `UPDATE` command by listing more than one assignment in the `SET` clause. For example:

```
UPDATE mytable SET a = 5, b = 3, c = 1 WHERE a > 0;
```

## 6.3. Deleting Data

So far we have explained how to add data to tables and how to change data. What remains is to discuss how to remove data that is no longer needed. Just as adding data is only possible in whole rows, you can only remove entire rows from a table. In the previous section we explained that SQL does not provide a way to directly address individual rows. Therefore, removing rows can only be done by specifying conditions that the rows to be removed have to match. If you have a primary key in the table then you can specify the exact row. But you can also remove groups of rows matching a condition, or you can remove all rows in the table at once.

You use the `DELETE` command to remove rows; the syntax is very similar to the `UPDATE` command. For instance, to remove all rows from the `products` table that have a price of 10, use:

```
DELETE FROM products WHERE price = 10;
```

If you simply write:

```
DELETE FROM products;
```

then all rows in the table will be deleted! Caveat programmer.

# Chapter 7. Queries

The previous chapters explained how to create tables, how to fill them with data, and how to manipulate that data. Now we finally discuss how to retrieve the data out of the database.

## 7.1. Overview

The process of retrieving or the command to retrieve data from a database is called a *query*. In SQL the *SELECT* command is used to specify queries. The general syntax of the *SELECT* command is

```
SELECT select_list FROM table_expression [sort_specification]
```

The following sections describe the details of the select list, the table expression, and the sort specification.

A simple kind of query has the form:

```
SELECT * FROM table1;
```

Assuming that there is a table called `table1`, this command would retrieve all rows and all columns from `table1`. (The method of retrieval depends on the client application. For example, the `psql` program will display an ASCII-art table on the screen, while client libraries will offer functions to extract individual values from the query result.) The select list specification `*` means all columns that the table expression happens to provide. A select list can also select a subset of the available columns or make calculations using the columns. For example, if `table1` has columns named `a`, `b`, and `c` (and perhaps others) you can make the following query:

```
SELECT a, b + c FROM table1;
```

(assuming that `b` and `c` are of a numerical data type). See Section 7.3 for more details.

`FROM table1` is a particularly simple kind of table expression: it reads just one table. In general, table expressions can be complex constructs of base tables, joins, and subqueries. But you can also omit the table expression entirely and use the *SELECT* command as a calculator:

```
SELECT 3 * 4;
```

This is more useful if the expressions in the select list return varying results. For example, you could call a function this way:

```
SELECT random();
```

## 7.2. Table Expressions

A *table expression* computes a table. The table expression contains a `FROM` clause that is optionally followed by `WHERE`, `GROUP BY`, and `HAVING` clauses. Trivial table expressions simply refer to a table on

disk, a so-called base table, but more complex expressions can be used to modify or combine base tables in various ways.

The optional `WHERE`, `GROUP BY`, and `HAVING` clauses in the table expression specify a pipeline of successive transformations performed on the table derived in the `FROM` clause. All these transformations produce a virtual table that provides the rows that are passed to the select list to compute the output rows of the query.

## 7.2.1. The `FROM` Clause

The *FROM Clause* derives a table from one or more other tables given in a comma-separated table reference list.

```
FROM table_reference [, table_reference [, ...]]
```

A table reference can be a table name (possibly schema-qualified), or a derived table such as a subquery, a table join, or complex combinations of these. If more than one table reference is listed in the `FROM` clause they are cross-joined (see below) to form the intermediate virtual table that can then be subject to transformations by the `WHERE`, `GROUP BY`, and `HAVING` clauses and is finally the result of the overall table expression.

When a table reference names a table that is the parent of a table inheritance hierarchy, the table reference produces rows of not only that table but all of its descendant tables, unless the key word `ONLY` precedes the table name. However, the reference produces only the columns that appear in the named table — any columns added in subtables are ignored.

### 7.2.1.1. Joined Tables

A joined table is a table derived from two other (real or derived) tables according to the rules of the particular join type. Inner, outer, and cross-joins are available.

## Join Types

Cross join

```
T1 CROSS JOIN T2
```

For each combination of rows from *T1* and *T2*, the derived table will contain a row consisting of all columns in *T1* followed by all columns in *T2*. If the tables have *N* and *M* rows respectively, the joined table will have *N \* M* rows.

`FROM T1 CROSS JOIN T2` is equivalent to `FROM T1, T2`. It is also equivalent to `FROM T1 INNER JOIN T2 ON TRUE` (see below).

Qualified joins

```
T1 { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2 ON boolean_expression
T1 { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2 USING ( join column list )
T1 NATURAL { [INNER] | { LEFT | RIGHT | FULL } [OUTER] } JOIN T2
```

The words `INNER` and `OUTER` are optional in all forms. `INNER` is the default; `LEFT`, `RIGHT`, and `FULL` imply an outer join.

The *join condition* is specified in the `ON` or `USING` clause, or implicitly by the word `NATURAL`. The join condition determines which rows from the two source tables are considered to “match”, as explained in detail below.

The `ON` clause is the most general kind of join condition: it takes a Boolean value expression of the same kind as is used in a `WHERE` clause. A pair of rows from *T1* and *T2* match if the `ON` expression evaluates to true for them.

`USING` is a shorthand notation: it takes a comma-separated list of column names, which the joined tables must have in common, and forms a join condition specifying equality of each of these pairs of columns. Furthermore, the output of a `JOIN USING` has one column for each of the equated pairs of input columns, followed by all of the other columns from each table. Thus, `USING (a, b, c)` is equivalent to `ON (t1.a = t2.a AND t1.b = t2.b AND t1.c = t2.c)` with the exception that if `ON` is used there will be two columns *a*, *b*, and *c* in the result, whereas with `USING` there will be only one of each.

Finally, `NATURAL` is a shorthand form of `USING`: it forms a `USING` list consisting of exactly those column names that appear in both input tables. As with `USING`, these columns appear only once in the output table.

The possible types of qualified join are:

#### INNER JOIN

For each row *R1* of *T1*, the joined table has a row for each row in *T2* that satisfies the join condition with *R1*.

#### LEFT OUTER JOIN

First, an inner join is performed. Then, for each row in *T1* that does not satisfy the join condition with any row in *T2*, a joined row is added with null values in columns of *T2*. Thus, the joined table unconditionally has at least one row for each row in *T1*.

#### RIGHT OUTER JOIN

First, an inner join is performed. Then, for each row in *T2* that does not satisfy the join condition with any row in *T1*, a joined row is added with null values in columns of *T1*. This is the converse of a left join: the result table will unconditionally have a row for each row in *T2*.

#### FULL OUTER JOIN

First, an inner join is performed. Then, for each row in *T1* that does not satisfy the join condition with any row in *T2*, a joined row is added with null values in columns of *T2*. Also, for each row of *T2* that does not satisfy the join condition with any row in *T1*, a joined row with null values in the columns of *T1* is added.

Joins of all types can be chained together or nested: either or both of *T1* and *T2* might be joined tables. Parentheses can be used around `JOIN` clauses to control the join order. In the absence of parentheses, `JOIN` clauses nest left-to-right.

To put this together, assume we have tables *t1*:

```

num | name
-----+-----
1   | a

```

```

2 | b
3 | c

```

and t2:

```

num | value
-----+-----
1 | xxx
3 | yyy
5 | zzz

```

then we get the following results for the various joins:

```
=> SELECT * FROM t1 CROSS JOIN t2;
```

```

num | name | num | value
-----+-----+-----+-----
1 | a    | 1 | xxx
1 | a    | 3 | yyy
1 | a    | 5 | zzz
2 | b    | 1 | xxx
2 | b    | 3 | yyy
2 | b    | 5 | zzz
3 | c    | 1 | xxx
3 | c    | 3 | yyy
3 | c    | 5 | zzz
(9 rows)

```

```
=> SELECT * FROM t1 INNER JOIN t2 ON t1.num = t2.num;
```

```

num | name | num | value
-----+-----+-----+-----
1 | a    | 1 | xxx
3 | c    | 3 | yyy
(2 rows)

```

```
=> SELECT * FROM t1 INNER JOIN t2 USING (num);
```

```

num | name | value
-----+-----+-----
1 | a    | xxx
3 | c    | yyy
(2 rows)

```

```
=> SELECT * FROM t1 NATURAL INNER JOIN t2;
```

```

num | name | value
-----+-----+-----
1 | a    | xxx
3 | c    | yyy
(2 rows)

```

```
=> SELECT * FROM t1 LEFT JOIN t2 ON t1.num = t2.num;
```

```

num | name | num | value
-----+-----+-----+-----
1 | a    | 1 | xxx
2 | b    |   |

```

```

    3 | c      |    3 | yyy
(3 rows)

```

```
=> SELECT * FROM t1 LEFT JOIN t2 USING (num);
```

```

  num | name | value
-----+-----+-----
    1 | a    | xxx
    2 | b    |
    3 | c    | yyy
(3 rows)

```

```
=> SELECT * FROM t1 RIGHT JOIN t2 ON t1.num = t2.num;
```

```

  num | name | num | value
-----+-----+-----+-----
    1 | a    |    1 | xxx
    3 | c    |    3 | yyy
      |      |    5 | zzz
(3 rows)

```

```
=> SELECT * FROM t1 FULL JOIN t2 ON t1.num = t2.num;
```

```

  num | name | num | value
-----+-----+-----+-----
    1 | a    |    1 | xxx
    2 | b    |      |
    3 | c    |    3 | yyy
      |      |    5 | zzz
(4 rows)

```

The join condition specified with `ON` can also contain conditions that do not relate directly to the join. This can prove useful for some queries but needs to be thought out carefully. For example:

```
=> SELECT * FROM t1 LEFT JOIN t2 ON t1.num = t2.num AND t2.value = 'xxx';
```

```

  num | name | num | value
-----+-----+-----+-----
    1 | a    |    1 | xxx
    2 | b    |      |
    3 | c    |      |
(3 rows)

```

### 7.2.1.2. Table and Column Aliases

A temporary name can be given to tables and complex table references to be used for references to the derived table in the rest of the query. This is called a *table alias*.

To create a table alias, write

```
FROM table_reference AS alias
```

or

```
FROM table_reference alias
```

The `AS` key word is noise. *alias* can be any identifier.

A typical application of table aliases is to assign short identifiers to long table names to keep the join clauses readable. For example:

```
SELECT * FROM some_very_long_table_name s JOIN another_fairly_long_name a ON s.id = a.num;
```

The alias becomes the new name of the table reference for the current query — it is no longer possible to refer to the table by the original name. Thus:

```
SELECT * FROM my_table AS m WHERE my_table.a > 5;
```

is not valid according to the SQL standard. In PostgreSQL this will draw an error if the `add_missing_from` configuration variable is `off` (as it is by default). If it is `on`, an implicit table reference will be added to the `FROM` clause, so the query is processed as if it were written as:

```
SELECT * FROM my_table AS m, my_table AS my_table WHERE my_table.a > 5;
```

That will result in a cross join, which is usually not what you want.

Table aliases are mainly for notational convenience, but it is necessary to use them when joining a table to itself, e.g.:

```
SELECT * FROM people AS mother JOIN people AS child ON mother.id = child.mother_id;
```

Additionally, an alias is required if the table reference is a subquery (see Section 7.2.1.3).

Parentheses are used to resolve ambiguities. In the following example, the first statement assigns the alias `b` to the second instance of `my_table`, but the second statement assigns the alias to the result of the join:

```
SELECT * FROM my_table AS a CROSS JOIN my_table AS b ...
SELECT * FROM (my_table AS a CROSS JOIN my_table) AS b ...
```

Another form of table aliasing gives temporary names to the columns of the table, as well as the table itself:

```
FROM table_reference [AS] alias ( column1 [, column2 [, ...]] )
```

If fewer column aliases are specified than the actual table has columns, the remaining columns are not renamed. This syntax is especially useful for self-joins or subqueries.

When an alias is applied to the output of a `JOIN` clause, using any of these forms, the alias hides the original names within the `JOIN`. For example:

```
SELECT a.* FROM my_table AS a JOIN your_table AS b ON ...
```

is valid SQL, but:

```
SELECT a.* FROM (my_table AS a JOIN your_table AS b ON ...) AS c
```

is not valid: the table alias `a` is not visible outside the alias `c`.

### 7.2.1.3. Subqueries

Subqueries specifying a derived table must be enclosed in parentheses and *must* be assigned a table alias name. (See Section 7.2.1.2.) For example:

```
FROM (SELECT * FROM table1) AS alias_name
```

This example is equivalent to `FROM table1 AS alias_name`. More interesting cases, which cannot be reduced to a plain join, arise when the subquery involves grouping or aggregation.

A subquery can also be a `VALUES` list:

```
FROM (VALUES ('anne', 'smith'), ('bob', 'jones'), ('joe', 'blow'))
      AS names(first, last)
```

Again, a table alias is required. Assigning alias names to the columns of the `VALUES` list is optional, but is good practice. For more information see Section 7.7.

### 7.2.1.4. Table Functions

Table functions are functions that produce a set of rows, made up of either base data types (scalar types) or composite data types (table rows). They are used like a table, view, or subquery in the `FROM` clause of a query. Columns returned by table functions can be included in `SELECT`, `JOIN`, or `WHERE` clauses in the same manner as a table, view, or subquery column.

If a table function returns a base data type, the single result column is named like the function. If the function returns a composite type, the result columns get the same names as the individual attributes of the type.

A table function can be aliased in the `FROM` clause, but it also can be left unaliased. If a function is used in the `FROM` clause with no alias, the function name is used as the resulting table name.

Some examples:

```
CREATE TABLE foo (fooid int, foosubid int, fooname text);

CREATE FUNCTION getfoo(int) RETURNS SETOF foo AS $$
    SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;

SELECT * FROM getfoo(1) AS t1;

SELECT * FROM foo
    WHERE foosubid IN (select foosubid from getfoo(foo.fooid) z
                      where z.fooid = foo.fooid);

CREATE VIEW vw_getfoo AS SELECT * FROM getfoo(1);

SELECT * FROM vw_getfoo;
```

In some cases it is useful to define table functions that can return different column sets depending on how they are invoked. To support this, the table function can be declared as returning the pseudotype `record`. When such a function is used in a query, the expected row structure must be specified in the query itself, so that the system can know how to parse and plan the query. Consider this example:

```
SELECT *
  FROM dblink('dbname=mydb', 'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text)
 WHERE proname LIKE 'bytea%';
```

The `dblink` function executes a remote query (see `contrib/dblink`). It is declared to return `record` since it might be used for any kind of query. The actual column set must be specified in the calling query so that the parser knows, for example, what `*` should expand to.

## 7.2.2. The `WHERE` Clause

The syntax of the *WHERE Clause* is

```
WHERE search_condition
```

where *search\_condition* is any value expression (see Section 4.2) that returns a value of type `boolean`.

After the processing of the `FROM` clause is done, each row of the derived virtual table is checked against the search condition. If the result of the condition is true, the row is kept in the output table, otherwise (that is, if the result is false or null) it is discarded. The search condition typically references at least some column of the table generated in the `FROM` clause; this is not required, but otherwise the `WHERE` clause will be fairly useless.

**Note:** The join condition of an inner join can be written either in the `WHERE` clause or in the `JOIN` clause. For example, these table expressions are equivalent:

```
FROM a, b WHERE a.id = b.id AND b.val > 5
```

and:

```
FROM a INNER JOIN b ON (a.id = b.id) WHERE b.val > 5
```

or perhaps even:

```
FROM a NATURAL JOIN b WHERE b.val > 5
```

Which one of these you use is mainly a matter of style. The `JOIN` syntax in the `FROM` clause is probably not as portable to other SQL database management systems. For outer joins there is no choice in any case: they must be done in the `FROM` clause. An `ON/USING` clause of an outer join is *not* equivalent to a `WHERE` condition, because it determines the addition of rows (for unmatched input rows) as well as the removal of rows from the final result.

Here are some examples of `WHERE` clauses:

```
SELECT ... FROM fdt WHERE c1 > 5

SELECT ... FROM fdt WHERE c1 IN (1, 2, 3)

SELECT ... FROM fdt WHERE c1 IN (SELECT c1 FROM t2)

SELECT ... FROM fdt WHERE c1 IN (SELECT c3 FROM t2 WHERE c2 = fdt.c1 + 10)

SELECT ... FROM fdt WHERE c1 BETWEEN (SELECT c3 FROM t2 WHERE c2 = fdt.c1 + 10) AND 100

SELECT ... FROM fdt WHERE EXISTS (SELECT c1 FROM t2 WHERE c2 > fdt.c1)
```

`fdt` is the table derived in the `FROM` clause. Rows that do not meet the search condition of the `WHERE` clause are eliminated from `fdt`. Notice the use of scalar subqueries as value expressions. Just like any other query, the subqueries can employ complex table expressions. Notice also how `fdt` is referenced in the subqueries. Qualifying `c1` as `fdt.c1` is only necessary if `c1` is also the name of a column in the derived input table of the subquery. But qualifying the column name adds clarity even when it is not needed. This example shows how the column naming scope of an outer query extends into its inner queries.

### 7.2.3. The `GROUP BY` and `HAVING` Clauses

After passing the `WHERE` filter, the derived input table might be subject to grouping, using the `GROUP BY` clause, and elimination of group rows using the `HAVING` clause.

```
SELECT select_list
  FROM ...
  [WHERE ...]
  GROUP BY grouping_column_reference [, grouping_column_reference]...
```

The *GROUP BY Clause* is used to group together those rows in a table that share the same values in all the columns listed. The order in which the columns are listed does not matter. The effect is to combine each set of rows sharing common values into one group row that is representative of all rows in the group. This is done to eliminate redundancy in the output and/or compute aggregates that apply to these groups. For instance:

```
=> SELECT * FROM test1;
  x | y
---+---
  a | 3
  c | 2
  b | 5
  a | 1
(4 rows)

=> SELECT x FROM test1 GROUP BY x;
  x
---
  a
  b
```

```
c
(3 rows)
```

In the second query, we could not have written `SELECT * FROM test1 GROUP BY x`, because there is no single value for the column `y` that could be associated with each group. The grouped-by columns can be referenced in the select list since they have a single value in each group.

In general, if a table is grouped, columns that are not used in the grouping cannot be referenced except in aggregate expressions. An example with aggregate expressions is:

```
=> SELECT x, sum(y) FROM test1 GROUP BY x;
 x | sum
---+-----
 a |    4
 b |    5
 c |    2
(3 rows)
```

Here `sum` is an aggregate function that computes a single value over the entire group. More information about the available aggregate functions can be found in Section 9.18.

**Tip:** Grouping without aggregate expressions effectively calculates the set of distinct values in a column. This can also be achieved using the `DISTINCT` clause (see Section 7.3.3).

Here is another example: it calculates the total sales for each product (rather than the total sales on all products):

```
SELECT product_id, p.name, (sum(s.units) * p.price) AS sales
FROM products p LEFT JOIN sales s USING (product_id)
GROUP BY product_id, p.name, p.price;
```

In this example, the columns `product_id`, `p.name`, and `p.price` must be in the `GROUP BY` clause since they are referenced in the query select list. (Depending on how exactly the products table is set up, name and price might be fully dependent on the product ID, so the additional groupings could theoretically be unnecessary, but this is not implemented yet.) The column `s.units` does not have to be in the `GROUP BY` list since it is only used in an aggregate expression (`sum(...)`), which represents the sales of a product. For each product, the query returns a summary row about all sales of the product.

In strict SQL, `GROUP BY` can only group by columns of the source table but PostgreSQL extends this to also allow `GROUP BY` to group by columns in the select list. Grouping by value expressions instead of simple column names is also allowed.

If a table has been grouped using a `GROUP BY` clause, but then only certain groups are of interest, the `HAVING` clause can be used, much like a `WHERE` clause, to eliminate groups from a grouped table. The syntax is:

```
SELECT select_list FROM ... [WHERE ...] GROUP BY ... HAVING boolean_expression
```

Expressions in the `HAVING` clause can refer both to grouped expressions and to ungrouped expressions (which necessarily involve an aggregate function).

Example:

```
=> SELECT x, sum(y) FROM test1 GROUP BY x HAVING sum(y) > 3;
```

```
x | sum
---+-----
a |    4
b |    5
(2 rows)
```

```
=> SELECT x, sum(y) FROM test1 GROUP BY x HAVING x < 'c';
```

```
x | sum
---+-----
a |    4
b |    5
(2 rows)
```

Again, a more realistic example:

```
SELECT product_id, p.name, (sum(s.units) * (p.price - p.cost)) AS profit
FROM products p LEFT JOIN sales s USING (product_id)
WHERE s.date > CURRENT_DATE - INTERVAL '4 weeks'
GROUP BY product_id, p.name, p.price, p.cost
HAVING sum(p.price * s.units) > 5000;
```

In the example above, the `WHERE` clause is selecting rows by a column that is not grouped (the expression is only true for sales during the last four weeks), while the `HAVING` clause restricts the output to groups with total gross sales over 5000. Note that the aggregate expressions do not necessarily need to be the same in all parts of the query.

## 7.3. Select Lists

As shown in the previous section, the table expression in the `SELECT` command constructs an intermediate virtual table by possibly combining tables, views, eliminating rows, grouping, etc. This table is finally passed on to processing by the *select list*. The select list determines which *columns* of the intermediate table are actually output.

### 7.3.1. Select-List Items

The simplest kind of select list is `*` which emits all columns that the table expression produces. Otherwise, a select list is a comma-separated list of value expressions (as defined in Section 4.2). For instance, it could be a list of column names:

```
SELECT a, b, c FROM ...
```

The columns names `a`, `b`, and `c` are either the actual names of the columns of tables referenced in the `FROM` clause, or the aliases given to them as explained in Section 7.2.1.2. The name space available in the

select list is the same as in the `WHERE` clause, unless grouping is used, in which case it is the same as in the `HAVING` clause.

If more than one table has a column of the same name, the table name must also be given, as in:

```
SELECT tbl1.a, tbl2.a, tbl1.b FROM ...
```

When working with multiple tables, it can also be useful to ask for all the columns of a particular table:

```
SELECT tbl1.*, tbl2.a FROM ...
```

(See also Section 7.2.2.)

If an arbitrary value expression is used in the select list, it conceptually adds a new virtual column to the returned table. The value expression is evaluated once for each result row, with the row's values substituted for any column references. But the expressions in the select list do not have to reference any columns in the table expression of the `FROM` clause; they could be constant arithmetic expressions as well, for instance.

### 7.3.2. Column Labels

The entries in the select list can be assigned names for further processing. The “further processing” in this case is an optional sort specification and the client application (e.g., column headers for display). For example:

```
SELECT a AS value, b + c AS sum FROM ...
```

If no output column name is specified using `AS`, the system assigns a default name. For simple column references, this is the name of the referenced column. For function calls, this is the name of the function. For complex expressions, the system will generate a generic name.

**Note:** The naming of output columns here is different from that done in the `FROM` clause (see Section 7.2.1.2). This pipeline will in fact allow you to rename the same column twice, but the name chosen in the select list is the one that will be passed on.

### 7.3.3. DISTINCT

After the select list has been processed, the result table can optionally be subject to the elimination of duplicate rows. The `DISTINCT` key word is written directly after `SELECT` to specify this:

```
SELECT DISTINCT select_list ...
```

(Instead of `DISTINCT` the key word `ALL` can be used to specify the default behavior of retaining all rows.)

Obviously, two rows are considered distinct if they differ in at least one column value. Null values are considered equal in this comparison.

Alternatively, an arbitrary expression can determine what rows are to be considered distinct:

```
SELECT DISTINCT ON (expression [, expression ...]) select_list ...
```

Here *expression* is an arbitrary value expression that is evaluated for all rows. A set of rows for which all the expressions are equal are considered duplicates, and only the first row of the set is kept in the output. Note that the “first row” of a set is unpredictable unless the query is sorted on enough columns to guarantee a unique ordering of the rows arriving at the `DISTINCT` filter. (`DISTINCT ON` processing occurs after `ORDER BY` sorting.)

The `DISTINCT ON` clause is not part of the SQL standard and is sometimes considered bad style because of the potentially indeterminate nature of its results. With judicious use of `GROUP BY` and subqueries in `FROM` the construct can be avoided, but it is often the most convenient alternative.

## 7.4. Combining Queries

The results of two queries can be combined using the set operations union, intersection, and difference. The syntax is

```
query1 UNION [ALL] query2
query1 INTERSECT [ALL] query2
query1 EXCEPT [ALL] query2
```

*query1* and *query2* are queries that can use any of the features discussed up to this point. Set operations can also be nested and chained, for example

```
query1 UNION query2 UNION query3
```

which really says

```
(query1 UNION query2) UNION query3
```

`UNION` effectively appends the result of *query2* to the result of *query1* (although there is no guarantee that this is the order in which the rows are actually returned). Furthermore, it eliminates duplicate rows from its result, in the same way as `DISTINCT`, unless `UNION ALL` is used.

`INTERSECT` returns all rows that are both in the result of *query1* and in the result of *query2*. Duplicate rows are eliminated unless `INTERSECT ALL` is used.

`EXCEPT` returns all rows that are in the result of *query1* but not in the result of *query2*. (This is sometimes called the *difference* between two queries.) Again, duplicates are eliminated unless `EXCEPT ALL` is used.

In order to calculate the union, intersection, or difference of two queries, the two queries must be “union compatible”, which means that they return the same number of columns and the corresponding columns have compatible data types, as described in Section 10.5.

## 7.5. Sorting Rows

After a query has produced an output table (after the select list has been processed) it can optionally be sorted. If sorting is not chosen, the rows will be returned in an unspecified order. The actual order in that case will depend on the scan and join plan types and the order on disk, but it must not be relied on. A particular output ordering can only be guaranteed if the sort step is explicitly chosen.

The `ORDER BY` clause specifies the sort order:

```
SELECT select_list
      FROM table_expression
      ORDER BY sort_expression1 [ASC | DESC] [NULLS { FIRST | LAST }]
              [, sort_expression2 [ASC | DESC] [NULLS { FIRST | LAST }] ...]
```

The sort expression(s) can be any expression that would be valid in the query’s select list. An example is:

```
SELECT a, b FROM table1 ORDER BY a + b, c;
```

When more than one expression is specified, the later values are used to sort rows that are equal according to the earlier values. Each expression can be followed by an optional `ASC` or `DESC` keyword to set the sort direction to ascending or descending. `ASC` order is the default. Ascending order puts smaller values first, where “smaller” is defined in terms of the `<` operator. Similarly, descending order is determined with the `>` operator.<sup>1</sup>

The `NULLS FIRST` and `NULLS LAST` options can be used to determine whether nulls appear before or after non-null values in the sort ordering. By default, null values sort as if larger than any non-null value; that is, `NULLS FIRST` is the default for `DESC` order, and `NULLS LAST` otherwise.

Note that the ordering options are considered independently for each sort column. For example `ORDER BY x, y DESC` means `ORDER BY x ASC, y DESC`, which is not the same as `ORDER BY x DESC, y DESC`.

For backwards compatibility with the SQL92 version of the standard, a *sort\_expression* can instead be the name or number of an output column, as in:

```
SELECT a + b AS sum, c FROM table1 ORDER BY sum;
SELECT a, max(b) FROM table1 GROUP BY a ORDER BY 1;
```

both of which sort by the first output column. Note that an output column name has to stand alone, it’s not allowed as part of an expression — for example, this is *not* correct:

```
SELECT a + b AS sum, c FROM table1 ORDER BY sum + c;           -- wrong
```

This restriction is made to reduce ambiguity. There is still ambiguity if an `ORDER BY` item is a simple name that could match either an output column name or a column from the table expression. The output column is used in such cases. This would only cause confusion if you use `AS` to rename an output column to match some other table column’s name.

`ORDER BY` can be applied to the result of a `UNION`, `INTERSECT`, or `EXCEPT` combination, but in this case it is only permitted to sort by output column names or numbers, not by expressions.

1. Actually, PostgreSQL uses the *default B-tree operator class* for the expression’s data type to determine the sort ordering for `ASC` and `DESC`. Conventionally, data types will be set up so that the `<` and `>` operators correspond to this sort ordering, but a user-defined data type’s designer could choose to do something different.

## 7.6. LIMIT and OFFSET

`LIMIT` and `OFFSET` allow you to retrieve just a portion of the rows that are generated by the rest of the query:

```
SELECT select_list
  FROM table_expression
  [ ORDER BY ... ]
  [ LIMIT { number | ALL } ] [ OFFSET number ]
```

If a limit count is given, no more than that many rows will be returned (but possibly less, if the query itself yields less rows). `LIMIT ALL` is the same as omitting the `LIMIT` clause.

`OFFSET` says to skip that many rows before beginning to return rows. `OFFSET 0` is the same as omitting the `OFFSET` clause. If both `OFFSET` and `LIMIT` appear, then `OFFSET` rows are skipped before starting to count the `LIMIT` rows that are returned.

When using `LIMIT`, it is important to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows. You might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? The ordering is unknown, unless you specified `ORDER BY`.

The query optimizer takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you give for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result *will give inconsistent results* unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

The rows skipped by an `OFFSET` clause still have to be computed inside the server; therefore a large `OFFSET` might be inefficient.

## 7.7. VALUES Lists

`VALUES` provides a way to generate a “constant table” that can be used in a query without having to actually create and populate a table on-disk. The syntax is

```
VALUES ( expression [, ...] ) [, ...]
```

Each parenthesized list of expressions generates a row in the table. The lists must all have the same number of elements (i.e., the number of columns in the table), and corresponding entries in each list must have compatible data types. The actual data type assigned to each column of the result is determined using the same rules as for `UNION` (see Section 10.5).

As an example:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

will return a table of two columns and three rows. It's effectively equivalent to:

```

SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';

```

By default, PostgreSQL assigns the names `column1`, `column2`, etc. to the columns of a `VALUES` table. The column names are not specified by the SQL standard and different database systems do it differently, so it's usually better to override the default names with a table alias list.

Syntactically, `VALUES` followed by expression lists is treated as equivalent to

```

SELECT select_list FROM table_expression

```

and can appear anywhere a `SELECT` can. For example, you can use it as an arm of a `UNION`, or attach a *sort\_specification* (`ORDER BY`, `LIMIT`, and/or `OFFSET`) to it. `VALUES` is most commonly used as the data source in an `INSERT` command, and next most commonly as a subquery.

For more information see *VALUES*.

# Chapter 8. Data Types

PostgreSQL has a rich set of native data types available to users. Users can add new types to PostgreSQL using the *CREATE TYPE* command.

Table 8-1 shows all the built-in general-purpose data types. Most of the alternative names listed in the “Aliases” column are the names used internally by PostgreSQL for historical reasons. In addition, some internally used or deprecated types are available, but they are not listed here.

**Table 8-1. Data Types**

Name	Aliases	Description
bigint	int8	signed eight-byte integer
bigserial	serial8	autoincrementing eight-byte integer
bit [ (n) ]		fixed-length bit string
bit varying [ (n) ]	varbit	variable-length bit string
boolean	bool	logical Boolean (true/false)
box		rectangular box in the plane
bytea		binary data (“byte array”)
character varying [ (n) ]	varchar [ (n) ]	variable-length character string
character [ (n) ]	char [ (n) ]	fixed-length character string
cidr		IPv4 or IPv6 network address
circle		circle in the plane
date		calendar date (year, month, day)
double precision	float8	double precision floating-point number
inet		IPv4 or IPv6 host address
integer	int, int4	signed four-byte integer
interval [ (p) ]		time span
line		infinite line in the plane
lseg		line segment in the plane
macaddr		MAC address
money		currency amount
numeric [ (p, s) ]	decimal [ (p, s) ]	exact numeric of selectable precision
path		geometric path in the plane
point		geometric point in the plane
polygon		closed geometric path in the plane

Name	Aliases	Description
real	float4	single precision floating-point number
smallint	int2	signed two-byte integer
serial	serial4	autoincrementing four-byte integer
text		variable-length character string
time [ (p) ] [ without time zone ]		time of day
time [ (p) ] with time zone	timetz	time of day, including time zone
timestamp [ (p) ] [ without time zone ]		date and time
timestamp [ (p) ] with time zone	timestampz	date and time, including time zone
tsquery		text search query
tsvector		text search document
txid_snapshot		user-level transaction ID snapshot
uuid		universally unique identifier
xml		XML data

**Compatibility:** The following types (or spellings thereof) are specified by SQL: `bigint`, `bit`, `bit varying`, `boolean`, `char`, `character varying`, `character`, `varchar`, `date`, `double precision`, `integer`, `interval`, `numeric`, `decimal`, `real`, `smallint`, `time` (with or without time zone), `timestamp` (with or without time zone), `xml`.

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL, such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function might lose accuracy when compared to the original input.

## 8.1. Numeric Types

Numeric types consist of two-, four-, and eight-byte integers, four- and eight-byte floating-point numbers, and selectable-precision decimals. Table 8-2 lists the available types.

**Table 8-2. Numeric Types**

Name	Storage Size	Description	Range
smallint	2 bytes	small-range integer	-32768 to +32767

Name	Storage Size	Description	Range
<code>integer</code>	4 bytes	usual choice for integer	-2147483648 to +2147483647
<code>bigint</code>	8 bytes	large-range integer	-9223372036854775808 to 9223372036854775807
<code>decimal</code>	variable	user-specified precision, exact	no limit
<code>numeric</code>	variable	user-specified precision, exact	no limit
<code>real</code>	4 bytes	variable-precision, inexact	6 decimal digits precision
<code>double precision</code>	8 bytes	variable-precision, inexact	15 decimal digits precision
<code>serial</code>	4 bytes	autoincrementing integer	1 to 2147483647
<code>bigserial</code>	8 bytes	large autoincrementing integer	1 to 9223372036854775807

The syntax of constants for the numeric types is described in Section 4.1.2. The numeric types have a full set of corresponding arithmetic operators and functions. Refer to Chapter 9 for more information. The following sections describe the types in detail.

### 8.1.1. Integer Types

The types `smallint`, `integer`, and `bigint` store whole numbers, that is, numbers without fractional components, of various ranges. Attempts to store values outside of the allowed range will result in an error.

The type `integer` is the usual choice, as it offers the best balance between range, storage size, and performance. The `smallint` type is generally only used if disk space is at a premium. The `bigint` type should only be used if the `integer` range is not sufficient, because the latter is definitely faster.

The `bigint` type might not function correctly on all platforms, since it relies on compiler support for eight-byte integers. On a machine without such support, `bigint` acts the same as `integer` (but still takes up eight bytes of storage). However, we are not aware of any reasonable platform where this is actually the case.

SQL only specifies the integer types `integer` (or `int`), `smallint`, and `bigint`. The type names `int2`, `int4`, and `int8` are extensions, which are shared with various other SQL database systems.

### 8.1.2. Arbitrary Precision Numbers

The type `numeric` can store numbers with up to 1000 digits of precision and perform calculations exactly. It is especially recommended for storing monetary amounts and other quantities where exactness is

required. However, arithmetic on `numeric` values is very slow compared to the integer types, or to the floating-point types described in the next section.

In what follows we use these terms: The *scale* of a `numeric` is the count of decimal digits in the fractional part, to the right of the decimal point. The *precision* of a `numeric` is the total count of significant digits in the whole number, that is, the number of digits to both sides of the decimal point. So the number 23.5141 has a precision of 6 and a scale of 4. Integers can be considered to have a scale of zero.

Both the maximum precision and the maximum scale of a `numeric` column can be configured. To declare a column of type `numeric` use the syntax:

```
NUMERIC(precision, scale)
```

The precision must be positive, the scale zero or positive. Alternatively:

```
NUMERIC(precision)
```

selects a scale of 0. Specifying:

```
NUMERIC
```

without any precision or scale creates a column in which numeric values of any precision and scale can be stored, up to the implementation limit on precision. A column of this kind will not coerce input values to any particular scale, whereas `numeric` columns with a declared scale will coerce input values to that scale. (The SQL standard requires a default scale of 0, i.e., coercion to integer precision. We find this a bit useless. If you're concerned about portability, always specify the precision and scale explicitly.)

If the scale of a value to be stored is greater than the declared scale of the column, the system will round the value to the specified number of fractional digits. Then, if the number of digits to the left of the decimal point exceeds the declared precision minus the declared scale, an error is raised.

Numeric values are physically stored without any extra leading or trailing zeroes. Thus, the declared precision and scale of a column are maximums, not fixed allocations. (In this sense the `numeric` type is more akin to `varchar(n)` than to `char(n)`.) The actual storage requirement is two bytes for each group of four decimal digits, plus five to eight bytes overhead.

In addition to ordinary numeric values, the `numeric` type allows the special value `NaN`, meaning “not-a-number”. Any operation on `NaN` yields another `NaN`. When writing this value as a constant in a SQL command, you must put quotes around it, for example `UPDATE table SET x = 'NaN'`. On input, the string `NaN` is recognized in a case-insensitive manner.

**Note:** In most implementations of the “not-a-number” concept, `NaN` is not considered equal to any other numeric value (including `NaN`). In order to allow `numeric` values to be sorted and used in tree-based indexes, PostgreSQL treats `NaN` values as equal, and greater than all non-`NaN` values.

The types `decimal` and `numeric` are equivalent. Both types are part of the SQL standard.

### 8.1.3. Floating-Point Types

The data types `real` and `double precision` are inexact, variable-precision numeric types. In practice, these types are usually implementations of IEEE Standard 754 for Binary Floating-Point Arithmetic (sin-

gle and double precision, respectively), to the extent that the underlying processor, operating system, and compiler support it.

Inexact means that some values cannot be converted exactly to the internal format and are stored as approximations, so that storing and printing back out a value might show slight discrepancies. Managing these errors and how they propagate through calculations is the subject of an entire branch of mathematics and computer science and will not be discussed further here, except for the following points:

- If you require exact storage and calculations (such as for monetary amounts), use the `numeric` type instead.
- If you want to do complicated calculations with these types for anything important, especially if you rely on certain behavior in boundary cases (infinity, underflow), you should evaluate the implementation carefully.
- Comparing two floating-point values for equality might or might not work as expected.

On most platforms, the `real` type has a range of at least  $1\text{E}-37$  to  $1\text{E}+37$  with a precision of at least 6 decimal digits. The `double precision` type typically has a range of around  $1\text{E}-307$  to  $1\text{E}+308$  with a precision of at least 15 digits. Values that are too large or too small will cause an error. Rounding might take place if the precision of an input number is too high. Numbers too close to zero that are not representable as distinct from zero will cause an underflow error.

In addition to ordinary numeric values, the floating-point types have several special values:

```
Infinity
-Infinity
NaN
```

These represent the IEEE 754 special values “infinity”, “negative infinity”, and “not-a-number”, respectively. (On a machine whose floating-point arithmetic does not follow IEEE 754, these values will probably not work as expected.) When writing these values as constants in a SQL command, you must put quotes around them, for example `UPDATE table SET x = 'Infinity'`. On input, these strings are recognized in a case-insensitive manner.

**Note:** IEEE754 specifies that `NaN` should not compare equal to any other floating-point value (including `NaN`). In order to allow floating-point values to be sorted and used in tree-based indexes, PostgreSQL treats `NaN` values as equal, and greater than all non-`NaN` values.

PostgreSQL also supports the SQL-standard notations `float` and `float(p)` for specifying inexact numeric types. Here, *p* specifies the minimum acceptable precision in binary digits. PostgreSQL accepts `float(1)` to `float(24)` as selecting the `real` type, while `float(25)` to `float(53)` select `double precision`. Values of *p* outside the allowed range draw an error. `float` with no precision specified is taken to mean `double precision`.

**Note:** Prior to PostgreSQL 7.4, the precision in `float(p)` was taken to mean so many decimal digits. This has been corrected to match the SQL standard, which specifies that the precision is measured in binary digits. The assumption that `real` and `double precision` have exactly 24 and 53 bits in

the mantissa respectively is correct for IEEE-standard floating point implementations. On non-IEEE platforms it might be off a little, but for simplicity the same ranges of  $p$  are used on all platforms.

### 8.1.4. Serial Types

The data types `serial` and `bigserial` are not true types, but merely a notational convenience for setting up unique identifier columns (similar to the `AUTO_INCREMENT` property supported by some other databases). In the current implementation, specifying:

```
CREATE TABLE tablename (
    colname SERIAL
);
```

is equivalent to specifying:

```
CREATE SEQUENCE tablename_colname_seq;
CREATE TABLE tablename (
    colname integer NOT NULL DEFAULT nextval('tablename_colname_seq')
);
ALTER SEQUENCE tablename_colname_seq OWNED BY tablename.colname;
```

Thus, we have created an integer column and arranged for its default values to be assigned from a sequence generator. A `NOT NULL` constraint is applied to ensure that a null value cannot be explicitly inserted, either. (In most cases you would also want to attach a `UNIQUE` or `PRIMARY KEY` constraint to prevent duplicate values from being inserted by accident, but this is not automatic.) Lastly, the sequence is marked as “owned by” the column, so that it will be dropped if the column or table is dropped.

**Note:** Prior to PostgreSQL 7.3, `serial` implied `UNIQUE`. This is no longer automatic. If you wish a `serial` column to be in a unique constraint or a primary key, it must now be specified, same as with any other data type.

To insert the next value of the sequence into the `serial` column, specify that the `serial` column should be assigned its default value. This can be done either by excluding the column from the list of columns in the `INSERT` statement, or through the use of the `DEFAULT` key word.

The type names `serial` and `serial4` are equivalent: both create `integer` columns. The type names `bigserial` and `serial8` work just the same way, except that they create a `bigint` column. `bigserial` should be used if you anticipate the use of more than  $2^{31}$  identifiers over the lifetime of the table.

The sequence created for a `serial` column is automatically dropped when the owning column is dropped. You can drop the sequence without dropping the column, but this will force removal of the column default expression.

## 8.2. Monetary Types

The `money` type stores a currency amount with a fixed fractional precision; see Table 8-3. Input is accepted in a variety of formats, including integer and floating-point literals, as well as “typical” currency formatting, such as `'$1,000.00'`. Output is generally in the latter form but depends on the locale. Non-quoted numeric values can be converted to `money` by casting the numeric value to `text` and then `money`:

```
SELECT 1234::text::money;
```

There is no simple way of doing the reverse in a locale-independent manner, namely casting a `money` value to a numeric type. If you know the currency symbol and thousands separator you can use `regexp_replace()`:

```
SELECT regexp_replace('52093.89'::money::text, '[$,]', '', 'g')::numeric;
```

Since the output of this data type is locale-sensitive, it may not work to load `money` data into a database that has a different setting of `lc_monetary`. To avoid problems, before restoring a dump make sure `lc_monetary` has the same or equivalent value as in the database that was dumped.

**Table 8-3. Monetary Types**

Name	Storage Size	Description	Range
money	8 bytes	currency amount	- 92233720368547758.08 to +92233720368547758.07

## 8.3. Character Types

**Table 8-4. Character Types**

Name	Description
<code>character varying(n)</code> , <code>varchar(n)</code>	variable-length with limit
<code>character(n)</code> , <code>char(n)</code>	fixed-length, blank padded
<code>text</code>	variable unlimited length

Table 8-4 shows the general-purpose character types available in PostgreSQL.

SQL defines two primary character types: `character varying(n)` and `character(n)`, where *n* is a positive integer. Both of these types can store strings up to *n* characters in length. An attempt to store a longer string into a column of these types will result in an error, unless the excess characters are all spaces, in which case the string will be truncated to the maximum length. (This somewhat bizarre exception is required by the SQL standard.) If the string to be stored is shorter than the declared length, values of type `character` will be space-padded; values of type `character varying` will simply store the shorter

string.

If one explicitly casts a value to `character varying(n)` or `character(n)`, then an over-length value will be truncated to *n* characters without raising an error. (This too is required by the SQL standard.)

The notations `varchar(n)` and `char(n)` are aliases for `character varying(n)` and `character(n)`, respectively. `character` without length specifier is equivalent to `character(1)`. If `character varying` is used without length specifier, the type accepts strings of any size. The latter is a PostgreSQL extension.

In addition, PostgreSQL provides the `text` type, which stores strings of any length. Although the type `text` is not in the SQL standard, several other SQL database management systems have it as well.

Values of type `character` are physically padded with spaces to the specified width *n*, and are stored and displayed that way. However, the padding spaces are treated as semantically insignificant. Trailing spaces are disregarded when comparing two values of type `character`, and they will be removed when converting a `character` value to one of the other string types. Note that trailing spaces *are* semantically significant in `character varying` and `text` values.

The storage requirement for a short string (up to 126 bytes) is 1 byte plus the actual string, which includes the space padding in the case of `character`. Longer strings have 4 bytes overhead instead of 1. Long strings are compressed by the system automatically, so the physical requirement on disk might be less. Very long values are also stored in background tables so that they do not interfere with rapid access to shorter column values. In any case, the longest possible character string that can be stored is about 1 GB. (The maximum value that will be allowed for *n* in the data type declaration is less than that. It wouldn't be very useful to change this because with multibyte character encodings the number of characters and bytes can be quite different anyway. If you desire to store long strings with no specific upper limit, use `text` or `character varying` without a length specifier, rather than making up an arbitrary length limit.)

**Tip:** There are no performance differences between these three types, apart from increased storage size when using the blank-padded type, and a few extra cycles to check the length when storing into a length-constrained column. While `character(n)` has performance advantages in some other database systems, it has no such advantages in PostgreSQL. In most situations `text` or `character varying` should be used instead.

Refer to Section 4.1.2.1 for information about the syntax of string literals, and to Chapter 9 for information about available operators and functions. The database character set determines the character set used to store textual values; for more information on character set support, refer to Section 22.2.

### Example 8-1. Using the character types

```
CREATE TABLE test1 (a character(4));
INSERT INTO test1 VALUES ('ok');
SELECT a, char_length(a) FROM test1; -- ❶
```

a	char_length
ok	2

```
CREATE TABLE test2 (b varchar(5));
INSERT INTO test2 VALUES ('ok');
INSERT INTO test2 VALUES ('good');
```

```

INSERT INTO test2 VALUES ('too long');
ERROR:  value too long for type character varying(5)
INSERT INTO test2 VALUES ('too long'::varchar(5)); -- explicit truncation
SELECT b, char_length(b) FROM test2;
   b   | char_length
-----+-----
ok     |          2
good   |          5
too l  |          5

```

❶ The `char_length` function is discussed in Section 9.4.

There are two other fixed-length character types in PostgreSQL, shown in Table 8-5. The `name` type exists *only* for storage of identifiers in the internal system catalogs and is not intended for use by the general user. Its length is currently defined as 64 bytes (63 usable characters plus terminator) but should be referenced using the constant `NAMEDATALEN`. The length is set at compile time (and is therefore adjustable for special uses); the default maximum length might change in a future release. The type `"char"` (note the quotes) is different from `char(1)` in that it only uses one byte of storage. It is internally used in the system catalogs as a poor-man’s enumeration type.

**Table 8-5. Special Character Types**

Name	Storage Size	Description
"char"	1 byte	single-byte internal type
name	64 bytes	internal type for object names

## 8.4. Binary Data Types

The `bytea` data type allows storage of binary strings; see Table 8-6.

**Table 8-6. Binary Data Types**

Name	Storage Size	Description
bytea	1 or 4 bytes plus the actual binary string	variable-length binary string

A binary string is a sequence of octets (or bytes). Binary strings are distinguished from character strings by two characteristics: First, binary strings specifically allow storing octets of value zero and other “non-printable” octets (usually, octets outside the range 32 to 126). Character strings disallow zero octets, and also disallow any other octet values and sequences of octet values that are invalid according to the database’s selected character set encoding. Second, operations on binary strings process the actual bytes, whereas the processing of character strings depends on locale settings. In short, binary strings are appropriate for storing data that the programmer thinks of as “raw bytes”, whereas character strings are appropriate for storing text.

When entering `bytea` values, octets of certain values *must* be escaped (but all octet values *can* be escaped)

when used as part of a string literal in an SQL statement. In general, to escape an octet, it is converted into the three-digit octal number equivalent of its decimal octet value, and preceded by two backslashes. Table 8-7 shows the characters that must be escaped, and gives the alternative escape sequences where applicable.

**Table 8-7. `bytea` Literal Escaped Octets**

Decimal Octet Value	Description	Escaped Input Representation	Example	Output Representation
0	zero octet	<code>E'\\000'</code>	<code>SELECT E'\\000'::bytea;</code>	<code>\000</code>
39	single quote	<code>'''</code> or <code>E'\\047'</code>	<code>SELECT E'\"::bytea;</code>	<code>'</code>
92	backslash	<code>E'\\\\'</code> or <code>E'\\134'</code>	<code>SELECT E'\\\\':bytea;</code>	<code>\\</code>
0 to 31 and 127 to 255	“non-printable” octets	<code>E'\\xxx'</code> (octal value)	<code>SELECT E'\\001'::bytea;</code>	<code>\001</code>

The requirement to escape “non-printable” octets actually varies depending on locale settings. In some instances you can get away with leaving them unescaped. Note that the result in each of the examples in Table 8-7 was exactly one octet in length, even though the output representation of the zero octet and backslash are more than one character.

The reason that you have to write so many backslashes, as shown in Table 8-7, is that an input string written as a string literal must pass through two parse phases in the PostgreSQL server. The first backslash of each pair is interpreted as an escape character by the string-literal parser (assuming escape string syntax is used) and is therefore consumed, leaving the second backslash of the pair. (Dollar-quoted strings can be used to avoid this level of escaping.) The remaining backslash is then recognized by the `bytea` input function as starting either a three digit octal value or escaping another backslash. For example, a string literal passed to the server as `E'\\001'` becomes `\001` after passing through the escape string parser. The `\001` is then sent to the `bytea` input function, where it is converted to a single octet with a decimal value of 1. Note that the single-quote character is not treated specially by `bytea`, so it follows the normal rules for string literals. (See also Section 4.1.2.1.)

`Bytea` octets are also escaped in the output. In general, each “non-printable” octet is converted into its equivalent three-digit octal value and preceded by one backslash. Most “printable” octets are represented by their standard representation in the client character set. The octet with decimal value 92 (backslash) has a special alternative output representation. Details are in Table 8-8.

**Table 8-8. `bytea` Output Escaped Octets**

Decimal Octet Value	Description	Escaped Output Representation	Example	Output Result
---------------------	-------------	-------------------------------	---------	---------------

Decimal Octet Value	Description	Escaped Output Representation	Example	Output Result
92	backslash	\\	SELECT E'\\134'::bytea;	\\
0 to 31 and 127 to 255	“non-printable” octets	\xxx (octal value)	SELECT E'\\001'::bytea;	\001
32 to 126	“printable” octets	client character set representation	SELECT E'\\176'::bytea;	~

Depending on the front end to PostgreSQL you use, you might have additional work to do in terms of escaping and unescaping `bytea` strings. For example, you might also have to escape line feeds and carriage returns if your interface automatically translates these.

The SQL standard defines a different binary string type, called `BLOB` or `BINARY LARGE OBJECT`. The input format is different from `bytea`, but the provided functions and operators are mostly the same.

## 8.5. Date/Time Types

PostgreSQL supports the full set of SQL date and time types, shown in Table 8-9. The operations available on these data types are described in Section 9.9.

**Table 8-9. Date/Time Types**

Name	Storage Size	Description	Low Value	High Value	Resolution
timestamp [ (p) ] [ without time zone ]	8 bytes	both date and time	4713 BC	5874897 AD	1 microsecond / 14 digits
timestamp [ (p) ] with time zone	8 bytes	both date and time, with time zone	4713 BC	5874897 AD	1 microsecond / 14 digits
interval [ (p) ]	12 bytes	time intervals	-178000000 years	178000000 years	1 microsecond / 14 digits
date	4 bytes	dates only	4713 BC	5874897 AD	1 day
time [ (p) ] [ without time zone ]	8 bytes	times of day only	00:00:00	24:00:00	1 microsecond / 14 digits
time [ (p) ] with time zone	12 bytes	times of day only, with time zone	00:00:00+1459	24:00:00-1459	1 microsecond / 14 digits

**Note:** Prior to PostgreSQL 7.3, writing just `timestamp` was equivalent to `timestamp with time`

`zone`. This was changed for SQL compliance.

`time`, `timestamp`, and `interval` accept an optional precision value *p* which specifies the number of fractional digits retained in the seconds field. By default, there is no explicit bound on precision. The allowed range of *p* is from 0 to 6 for the `timestamp` and `interval` types.

**Note:** When `timestamp` values are stored as double precision floating-point numbers (currently the default), the effective limit of precision might be less than 6. `timestamp` values are stored as seconds before or after midnight 2000-01-01. Microsecond precision is achieved for dates within a few years of 2000-01-01, but the precision degrades for dates further away. When `timestamp` values are stored as eight-byte integers (a compile-time option), microsecond precision is available over the full range of values. However eight-byte integer timestamps have a more limited range of dates than shown above: from 4713 BC up to 294276 AD. The same compile-time option also determines whether `time` and `interval` values are stored as floating-point or eight-byte integers. In the floating-point case, large `interval` values degrade in precision as the size of the interval increases.

For the `time` types, the allowed range of *p* is from 0 to 6 when eight-byte integer storage is used, or from 0 to 10 when floating-point storage is used.

The type `time with time zone` is defined by the SQL standard, but the definition exhibits properties which lead to questionable usefulness. In most cases, a combination of `date`, `time`, `timestamp` without `time zone`, and `timestamp with time zone` should provide a complete range of date/time functionality required by any application.

The types `abstime` and `reltime` are lower precision types which are used internally. You are discouraged from using these types in new applications and are encouraged to move any old ones over when appropriate. Any or all of these internal types might disappear in a future release.

### 8.5.1. Date/Time Input

Date and time input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others. For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields. Set the `DateStyle` parameter to `MDY` to select month-day-year interpretation, `DMY` to select day-month-year interpretation, or `YMD` to select year-month-day interpretation.

PostgreSQL is more flexible in handling date/time input than the SQL standard requires. See Appendix B for the exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones.

Remember that any date or time literal input needs to be enclosed in single quotes, like text strings. Refer to Section 4.1.2.5 for more information. SQL requires the following syntax

```
type [ (p) ] 'value'
```

where *p* in the optional precision specification is an integer corresponding to the number of fractional digits in the seconds field. Precision can be specified for `time`, `timestamp`, and `interval` types. The allowed values are mentioned above. If no precision is specified in a constant specification, it defaults to the precision of the literal value.

### 8.5.1.1. Dates

Table 8-10 shows some possible inputs for the `date` type.

**Table 8-10. Date Input**

Example	Description
January 8, 1999	unambiguous in any <code>datestyle</code> input mode
1999-01-08	ISO 8601; January 8 in any mode (recommended format)
1/8/1999	January 8 in <code>MDY</code> mode; August 1 in <code>DMY</code> mode
1/18/1999	January 18 in <code>MDY</code> mode; rejected in other modes
01/02/03	January 2, 2003 in <code>MDY</code> mode; February 1, 2003 in <code>DMY</code> mode; February 3, 2001 in <code>YMD</code> mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in <code>YMD</code> mode, else error
08-Jan-99	January 8, except error in <code>YMD</code> mode
Jan-08-99	January 8, except error in <code>YMD</code> mode
19990108	ISO 8601; January 8, 1999 in any mode
990108	ISO 8601; January 8, 1999 in any mode
1999.008	year and day of year
J2451187	Julian day
January 8, 99 BC	year 99 before the Common Era

### 8.5.1.2. Times

The time-of-day types are `time [ (p) ]` without time zone and `time [ (p) ]` with time zone. Writing just `time` is equivalent to `time without time zone`.

Valid input for these types consists of a time of day followed by an optional time zone. (See Table 8-11 and Table 8-12.) If a time zone is specified in the input for `time without time zone`, it is silently ignored. You can also specify a date but it will be ignored, except when you use a time zone name that involves a daylight-savings rule, such as `America/New_York`. In this case specifying the date is required in order to determine whether standard or daylight-savings time applies. The appropriate time zone offset is recorded in the `time with time zone` value.

**Table 8-11. Time Input**

Example	Description
04:05:06.789	ISO 8601
04:05:06	ISO 8601
04:05	ISO 8601

Example	Description
040506	ISO 8601
04:05 AM	same as 04:05; AM does not affect value
04:05 PM	same as 16:05; input hour must be <= 12
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	time zone specified by abbreviation
2003-04-12 04:05:06 America/New_York	time zone specified by full name

**Table 8-12. Time Zone Input**

Example	Description
PST	Abbreviation (for Pacific Standard Time)
America/New_York	Full time zone name
PST8PDT	POSIX-style time zone specification
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST
zulu	Military abbreviation for UTC
z	Short form of zulu

Refer to Section 8.5.3 for more information on how to specify time zones.

### 8.5.1.3. Time Stamps

Valid input for the time stamp types consists of a concatenation of a date and a time, followed by an optional time zone, followed by an optional AD or BC. (Alternatively, AD/BC can appear before the time zone, but this is not the preferred ordering.) Thus:

```
1999-01-08 04:05:06
```

and:

```
1999-01-08 04:05:06 -8:00
```

are valid values, which follow the ISO 8601 standard. In addition, the wide-spread format:

```
January 8 04:05:06 1999 PST
```

is supported.

The SQL standard differentiates timestamp without time zone and timestamp with time zone literals by the presence of a “+” or “-”. Hence, according to the standard,

```
TIMESTAMP '2004-10-19 10:23:54'
```

is a timestamp without time zone, while

```
TIMESTAMP '2004-10-19 10:23:54+02'
```

is a timestamp with time zone. PostgreSQL never examines the content of a literal string before determining its type, and therefore will treat both of the above as timestamp without time zone. To ensure that a literal is treated as timestamp with time zone, give it the correct explicit type:

```
TIMESTAMP WITH TIME ZONE '2004-10-19 10:23:54+02'
```

In a literal that has been decided to be timestamp without time zone, PostgreSQL will silently ignore any time zone indication. That is, the resulting value is derived from the date/time fields in the input value, and is not adjusted for time zone.

For timestamp with time zone, the internally stored value is always in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, GMT). An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone. If no time zone is stated in the input string, then it is assumed to be in the time zone indicated by the system's `timezone` parameter, and is converted to UTC using the offset for the `timezone` zone.

When a timestamp with time zone value is output, it is always converted from UTC to the current `timezone` zone, and displayed as local time in that zone. To see the time in another time zone, either change `timezone` or use the `AT TIME ZONE` construct (see Section 9.9.3).

Conversions between timestamp without time zone and timestamp with time zone normally assume that the timestamp without time zone value should be taken or given as `timezone` local time. A different zone reference can be specified for the conversion using `AT TIME ZONE`.

### 8.5.1.4. Intervals

interval values can be written with the following syntax:

```
[@] quantity unit [quantity unit...] [direction]
```

Where: *quantity* is a number (possibly signed); *unit* is microsecond, millisecond, second, minute, hour, day, week, month, year, decade, century, millennium, or abbreviations or plurals of these units; *direction* can be `ago` or empty. The at sign (@) is optional noise. The amounts of different units are implicitly added up with appropriate sign accounting.

Quantities of days, hours, minutes, and seconds can be specified without explicit unit markings. For example, `'1 12:59:10'` is read the same as `'1 day 12 hours 59 min 10 sec'`.

The optional subsecond precision *p* should be between 0 and 6, and defaults to the precision of the input literal.

Internally interval values are stored as months, days, and seconds. This is done because the number of days in a month varies, and a day can have 23 or 25 hours if a daylight savings time adjustment is involved. Because intervals are usually created from constant strings or timestamp subtraction, this storage method works well in most cases. Functions `justify_days` and `justify_hours` are available for adjusting days and hours that overflow their normal periods.

### 8.5.1.5. Special Values

PostgreSQL supports several special date/time input values for convenience, as shown in Table 8-13. The values `infinity` and `-infinity` are specially represented inside the system and will be displayed the same way; but the others are simply notational shorthands that will be converted to ordinary date/time values when read. (In particular, `now` and related strings are converted to a specific time value as soon as they are read.) All of these values need to be written in single quotes when used as constants in SQL commands.

**Table 8-13. Special Date/Time Inputs**

Input String	Valid Types	Description
<code>epoch</code>	<code>date</code> , <code>timestamp</code>	1970-01-01 00:00:00+00 (Unix system time zero)
<code>infinity</code>	<code>timestamp</code>	later than all other time stamps
<code>-infinity</code>	<code>timestamp</code>	earlier than all other time stamps
<code>now</code>	<code>date</code> , <code>time</code> , <code>timestamp</code>	current transaction's start time
<code>today</code>	<code>date</code> , <code>timestamp</code>	midnight today
<code>tomorrow</code>	<code>date</code> , <code>timestamp</code>	midnight tomorrow
<code>yesterday</code>	<code>date</code> , <code>timestamp</code>	midnight yesterday
<code>allballs</code>	<code>time</code>	00:00:00.00 UTC

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type: `CURRENT_DATE`, `CURRENT_TIME`, `CURRENT_TIMESTAMP`, `LOCALTIME`, `LOCALTIMESTAMP`. The latter four accept an optional subsecond precision specification. (See Section 9.9.4.) Note however that these are SQL functions and are *not* recognized as data input strings.

### 8.5.2. Date/Time Output

The output format of the date/time types can be set to one of the four styles ISO 8601, SQL (Ingres), traditional POSTGRES, and German, using the command `SET datestyle`. The default is the ISO format. (The SQL standard requires the use of the ISO 8601 format. The name of the “SQL” output format is a historical accident.) Table 8-14 shows examples of each output style. The output of the `date` and `time` types is of course only the date or time part in accordance with the given examples.

**Table 8-14. Date/Time Output Styles**

Style Specification	Description	Example
ISO	ISO 8601/SQL standard	1997-12-17 07:37:16-08
SQL	traditional style	12/17/1997 07:37:16.00 PST
POSTGRES	original style	Wed Dec 17 07:37:16 1997 PST
German	regional style	17.12.1997 07:37:16.00 PST

In the SQL and POSTGRES styles, day appears before month if DMY field ordering has been specified,

otherwise month appears before day. (See Section 8.5.1 for how this setting also affects interpretation of input values.) Table 8-15 shows an example.

**Table 8-15. Date Order Conventions**

datestyle Setting	Input Ordering	Example Output
SQL, DMY	<i>day/month/year</i>	17/12/1997 15:37:16.00 CET
SQL, MDY	<i>month/day/year</i>	12/17/1997 07:37:16.00 PST
Postgres, DMY	<i>day/month/year</i>	Wed 17 Dec 07:37:16 1997 PST

interval output looks like the input format, except that units like `century` or `week` are converted to years and days and `ago` is converted to an appropriate sign. In ISO mode the output looks like:

```
[ quantity unit [ ... ] ] [ days ] [ hours:minutes:seconds ]
```

The date/time styles can be selected by the user using the `SET datestyle` command, the `DateStyle` parameter in the `postgresql.conf` configuration file, or the `PGDATESTYLE` environment variable on the server or client. The formatting function `to_char` (see Section 9.8) is also available as a more flexible way to format the date/time output.

### 8.5.3. Time Zones

Time zones, and time-zone conventions, are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules. PostgreSQL currently supports daylight-savings rules over the time period 1902 through 2038 (corresponding to the full range of conventional Unix system time). Times outside that range are taken to be in “standard time” for the selected time zone, no matter what part of the year they fall in.

PostgreSQL endeavors to be compatible with the SQL standard definitions for typical usage. However, the SQL standard has an odd mix of date and time types and capabilities. Two obvious problems are:

- Although the `date` type does not have an associated time zone, the `time` type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, we recommend using date/time types that contain both date and time when using time zones. We recommend *not* using the type `time with time zone` (though it is supported by PostgreSQL for legacy applications and for compliance with the SQL standard). PostgreSQL assumes your local time zone for any type containing only date or time.

All timezone-aware dates and times are stored internally in UTC. They are converted to local time in the zone specified by the `timezone` configuration parameter before being displayed to the client.

PostgreSQL allows you to specify time zones in three different forms:

- A full time zone name, for example `America/New_York`. The recognized time zone names are listed in the `pg_timezone_names` view (see Section 44.56). PostgreSQL uses the widely-used `zic` time zone data for this purpose, so the same names are also recognized by much other software.
- A time zone abbreviation, for example `PST`. Such a specification merely defines a particular offset from UTC, in contrast to full time zone names which might imply a set of daylight savings transition-date rules as well. The recognized abbreviations are listed in the `pg_timezone_abbrevs` view (see Section 44.55). You cannot set the configuration parameters `timezone` or `log_timezone` using a time zone abbreviation, but you can use abbreviations in date/time input values and with the `AT TIME ZONE` operator.
- In addition to the `timezone` names and abbreviations, PostgreSQL will accept POSIX-style time zone specifications of the form `STDoffset` or `STDoffsetDST`, where `STD` is a zone abbreviation, `offset` is a numeric offset in hours west from UTC, and `DST` is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if `EST5EDT` were not already a recognized zone name, it would be accepted and would be functionally equivalent to USA East Coast time. When a daylight-savings zone name is present, it is assumed to be used according to the same daylight-savings transition rules used in the `zic` time zone database's `posixrules` entry. In a standard PostgreSQL installation, `posixrules` is the same as `US/Eastern`, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the `posixrules` file.

There is a conceptual and practical difference between the abbreviations and the full names: abbreviations always represent a fixed offset from UTC, whereas most of the full names imply a local daylight-savings time rule and so have two possible UTC offsets.

One should be wary that the POSIX-style time zone feature can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC. Another issue to keep in mind is that in POSIX time zone names, positive offsets are used for locations *west* of Greenwich. Everywhere else, PostgreSQL follows the ISO-8601 convention that positive `timezone` offsets are *east* of Greenwich.

In all cases, `timezone` names are recognized case-insensitively. (This is a change from PostgreSQL versions prior to 8.2, which were case-sensitive in some contexts and not others.)

Neither full names nor abbreviations are hard-wired into the server; they are obtained from configuration files stored under `.../share/timezone/` and `.../share/timezonesets/` of the installation directory (see Section B.3).

The `timezone` configuration parameter can be set in the file `postgresql.conf`, or in any of the other standard ways described in Chapter 18. There are also several special ways to set it:

- If `timezone` is not specified in `postgresql.conf` nor as a server command-line option, the server attempts to use the value of the `TZ` environment variable as the default time zone. If `TZ` is not defined or is not any of the time zone names known to PostgreSQL, the server attempts to determine the operating system's default time zone by checking the behavior of the C library function `localtime()`. The default time zone is selected as the closest match among PostgreSQL's known time zones. (These rules are also used to choose the default value of `log_timezone`, if it is not specified.)

- The SQL command `SET TIME ZONE` sets the time zone for the session. This is an alternative spelling of `SET TIMEZONE TO` with a more SQL-spec-compatible syntax.
- The `PGTZ` environment variable, if set at the client, is used by libpq applications to send a `SET TIME ZONE` command to the server upon connection.

### 8.5.4. Internals

PostgreSQL uses Julian dates for all date/time calculations. They have the nice property of correctly predicting/calculating any date more recent than 4713 BC to far into the future, using the assumption that the length of the year is 365.2425 days.

Date conventions before the 19th century make for interesting reading, but are not consistent enough to warrant coding into a date/time handler.

## 8.6. Boolean Type

PostgreSQL provides the standard SQL type `boolean`. `boolean` can have one of only two states: “true” or “false”. A third state, “unknown”, is represented by the SQL null value.

Valid literal values for the “true” state are:

```
TRUE
't'
'true'
'y'
'yes'
'1'
```

For the “false” state, the following values can be used:

```
FALSE
'f'
'false'
'n'
'no'
'0'
```

Leading and trailing whitespace is ignored. Using the key words `TRUE` and `FALSE` is preferred (and SQL-compliant).

#### Example 8-2. Using the `boolean` type

```
CREATE TABLE test1 (a boolean, b text);
INSERT INTO test1 VALUES (TRUE, 'sic est');
INSERT INTO test1 VALUES (FALSE, 'non est');
SELECT * FROM test1;
```

```

a |      b
---+-----
t | sic est
f | non est

SELECT * FROM test1 WHERE a;
a |      b
---+-----
t | sic est

```

Example 8-2 shows that `boolean` values are output using the letters `t` and `f`.

`boolean` uses 1 byte of storage.

## 8.7. Enumerated Types

Enumerated (`enum`) types are data types that are comprised of a static, predefined set of values with a specific order. They are equivalent to the `enum` types in a number of programming languages. An example of an `enum` type might be the days of the week, or a set of status values for a piece of data.

### 8.7.1. Declaration of Enumerated Types

Enum types are created using the *CREATE TYPE* command, for example:

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
```

Once created, the `enum` type can be used in table and function definitions much like any other type:

#### Example 8-3. Basic Enum Usage

```

CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (
    name text,
    current_mood mood
);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
name | current_mood
-----+-----
Moe  | happy
(1 row)

```

### 8.7.2. Ordering

The ordering of the values in an `enum` type is the order in which the values were listed when the type was declared. All standard comparison operators and related aggregate functions are supported for `enums`. For example:

**Example 8-4. Enum Ordering**

```

INSERT INTO person VALUES ('Larry', 'sad');
INSERT INTO person VALUES ('Curly', 'ok');
SELECT * FROM person WHERE current_mood > 'sad';
  name | current_mood
-----+-----
  Moe  | happy
  Curly | ok
(2 rows)

SELECT * FROM person WHERE current_mood > 'sad' ORDER BY current_mood;
  name | current_mood
-----+-----
  Curly | ok
  Moe   | happy
(2 rows)

SELECT name FROM person
  WHERE current_mood = (SELECT MIN(current_mood) FROM person);
  name
-----
  Larry
(1 row)

```

**8.7.3. Type Safety**

Enumerated types are completely separate data types and may not be compared with each other.

**Example 8-5. Lack of Casting**

```

CREATE TYPE happiness AS ENUM ('happy', 'very happy', 'ecstatic');
CREATE TABLE holidays (
    num_weeks int,
    happiness happiness
);
INSERT INTO holidays(num_weeks,happiness) VALUES (4, 'happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (6, 'very happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (8, 'ecstatic');
INSERT INTO holidays(num_weeks,happiness) VALUES (2, 'sad');
ERROR:  invalid input value for enum happiness: "sad"
SELECT person.name, holidays.num_weeks FROM person, holidays
  WHERE person.current_mood = holidays.happiness;
ERROR:  operator does not exist: mood = happiness

```

If you really need to do something like that, you can either write a custom operator or add explicit casts to your query:

**Example 8-6. Comparing Different Enums by Casting to Text**

```
SELECT person.name, holidays.num_weeks FROM person, holidays
   WHERE person.current_mood::text = holidays.happiness::text;
 name | num_weeks
-----+-----
 Moe  |          4
(1 row)
```

**8.7.4. Implementation Details**

An enum value occupies four bytes on disk. The length of an enum value's textual label is limited by the `NAMEDATALEN` setting compiled into PostgreSQL; in standard builds this means at most 63 bytes.

Enum labels are case sensitive, so 'happy' is not the same as 'HAPPY'. Spaces in the labels are significant, too.

**8.8. Geometric Types**

Geometric data types represent two-dimensional spatial objects. Table 8-16 shows the geometric types available in PostgreSQL. The most fundamental type, the point, forms the basis for all of the other types.

**Table 8-16. Geometric Types**

Name	Storage Size	Representation	Description
point	16 bytes	Point on the plane	(x,y)
line	32 bytes	Infinite line (not fully implemented)	((x1,y1),(x2,y2))
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Rectangular box	((x1,y1),(x2,y2))
path	16+16n bytes	Closed path (similar to polygon)	((x1,y1),...)
path	16+16n bytes	Open path	[(x1,y1),...]
polygon	40+16n bytes	Polygon (similar to closed path)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center and radius)

A rich set of functions and operators is available to perform various geometric operations such as scaling, translation, rotation, and determining intersections. They are explained in Section 9.11.

### 8.8.1. Points

Points are the fundamental two-dimensional building block for geometric types. Values of type `point` are specified using the following syntax:

```
( x , y )
  x , y
```

where `x` and `y` are the respective coordinates as floating-point numbers.

### 8.8.2. Line Segments

Line segments (`lseg`) are represented by pairs of points. Values of type `lseg` are specified using the following syntax:

```
( ( x1 , y1 ) , ( x2 , y2 ) )
  ( x1 , y1 ) , ( x2 , y2 )
    x1 , y1 , x2 , y2
```

where  $(x1, y1)$  and  $(x2, y2)$  are the end points of the line segment.

### 8.8.3. Boxes

Boxes are represented by pairs of points that are opposite corners of the box. Values of type `box` are specified using the following syntax:

```
( ( x1 , y1 ) , ( x2 , y2 ) )
  ( x1 , y1 ) , ( x2 , y2 )
    x1 , y1 , x2 , y2
```

where  $(x1, y1)$  and  $(x2, y2)$  are any two opposite corners of the box.

Boxes are output using the first syntax. The corners are reordered on input to store the upper right corner, then the lower left corner. Other corners of the box can be entered, but the lower left and upper right corners are determined from the input and stored.

### 8.8.4. Paths

Paths are represented by lists of connected points. Paths can be *open*, where the first and last points in the list are not considered connected, or *closed*, where the first and last points are considered connected.

Values of type `path` are specified using the following syntax:

```
( ( x1 , y1 ) , ... , ( xn , yn ) )
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
  ( x1 , y1 ) , ... , ( xn , yn )
  ( x1 , y1 , ... , xn , yn )
    x1 , y1 , ... , xn , yn
```

where the points are the end points of the line segments comprising the path. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path.

Paths are output using the first syntax.

### 8.8.5. Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons should probably be considered equivalent to closed paths, but are stored differently and have their own set of support routines.

Values of type `polygon` are specified using the following syntax:

```
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1 , ... , xn , yn )
x1 , y1 , ... , xn , yn
```

where the points are the end points of the line segments comprising the boundary of the polygon.

Polygons are output using the first syntax.

### 8.8.6. Circles

Circles are represented by a center point and a radius. Values of type `circle` are specified using the following syntax:

```
< ( x , y ) , r >
( ( x , y ) , r )
( x , y ) , r
x , y , r
```

where  $(x, y)$  is the center and  $r$  is the radius of the circle.

Circles are output using the first syntax.

## 8.9. Network Address Types

PostgreSQL offers data types to store IPv4, IPv6, and MAC addresses, as shown in Table 8-17. It is preferable to use these types instead of plain text types to store network addresses, because these types offer input error checking and several specialized operators and functions (see Section 9.12).

**Table 8-17. Network Address Types**

Name	Storage Size	Description
<code>cidr</code>	7 or 19 bytes	IPv4 and IPv6 networks
<code>inet</code>	7 or 19 bytes	IPv4 and IPv6 hosts and networks

Name	Storage Size	Description
macaddr	6 bytes	MAC addresses

When sorting `inet` or `cidr` data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped into IPv6 addresses, such as `::10.2.3.4` or `::ffff:10.4.3.2`.

### 8.9.1. `inet`

The `inet` type holds an IPv4 or IPv6 host address, and optionally the identity of the subnet it is in, all in one field. The subnet identity is represented by stating how many bits of the host address represent the network address (the “netmask”). If the netmask is 32 and the address is IPv4, then the value does not indicate a subnet, only a single host. In IPv6, the address length is 128 bits, so 128 bits specify a unique host address. Note that if you want to accept networks only, you should use the `cidr` type rather than `inet`.

The input format for this type is `address/y` where `address` is an IPv4 or IPv6 address and `y` is the number of bits in the netmask. If the `/y` part is left off, then the netmask is 32 for IPv4 and 128 for IPv6, so the value represents just a single host. On display, the `/y` portion is suppressed if the netmask specifies a single host.

### 8.9.2. `cidr`

The `cidr` type holds an IPv4 or IPv6 network specification. Input and output formats follow Classless Internet Domain Routing conventions. The format for specifying networks is `address/y` where `address` is the network represented as an IPv4 or IPv6 address, and `y` is the number of bits in the netmask. If `y` is omitted, it is calculated using assumptions from the older classful network numbering system, except that it will be at least large enough to include all of the octets written in the input. It is an error to specify a network address that has bits set to the right of the specified netmask.

Table 8-18 shows some examples.

**Table 8-18. `cidr` Type Input Examples**

<code>cidr</code> Input	<code>cidr</code> Output	<code>abbrev(cidr)</code>
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
128.1	128.1.0.0/16	128.1/16
128	128.0.0.0/16	128.0/16
128.1.2	128.1.2.0/24	128.1.2/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8

<b>cidr Input</b>	<b>cidr Output</b>	<b>abbrev(cidr)</b>
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32
2001:4f8:3:ba::/64	2001:4f8:3:ba::/64	2001:4f8:3:ba::/64
2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1
::ffff:1.2.3.0/120	::ffff:1.2.3.0/120	::ffff:1.2.3/120
::ffff:1.2.3.0/128	::ffff:1.2.3.0/128	::ffff:1.2.3.0/128

### 8.9.3. inet VS. cidr

The essential difference between `inet` and `cidr` data types is that `inet` accepts values with nonzero bits to the right of the netmask, whereas `cidr` does not.

**Tip:** If you do not like the output format for `inet` or `cidr` values, try the functions `host`, `text`, and `abbrev`.

### 8.9.4. macaddr

The `macaddr` type stores MAC addresses, i.e., Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in various customary formats, including

```
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08-00-2b-01-02-03'
'08:00:2b:01:02:03'
```

which would all specify the same address. Upper and lower case is accepted for the digits `a` through `f`. Output is always in the last of the forms shown.

## 8.10. Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store or visualize bit masks. There are two SQL bit types: `bit(n)` and `bit varying(n)`, where `n` is a positive integer.

`bit` type data must match the length `n` exactly; it is an error to attempt to store shorter or longer bit strings. `bit varying` data is of variable length up to the maximum length `n`; longer strings will be rejected. Writing `bit` without a length is equivalent to `bit(1)`, while `bit varying` without a length specification means unlimited length.

**Note:** If one explicitly casts a bit-string value to `bit(n)`, it will be truncated or zero-padded on the right to be exactly *n* bits, without raising an error. Similarly, if one explicitly casts a bit-string value to `bit varying(n)`, it will be truncated on the right if it is more than *n* bits.

Refer to Section 4.1.2.3 for information about the syntax of bit string constants. Bit-logical operators and string manipulation functions are available; see Section 9.6.

### Example 8-7. Using the bit string types

```
CREATE TABLE test (a BIT(3), b BIT VARYING(5));
INSERT INTO test VALUES (B'101', B'00');
INSERT INTO test VALUES (B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
INSERT INTO test VALUES (B'10'::bit(3), B'101');
SELECT * FROM test;
 a | b
-----+-----
101 | 00
100 | 101
```

A bit string value requires 1 byte for each group of 8 bits, plus 5 or 8 bytes overhead depending on the length of the string (but long values may be compressed or moved out-of-line, as explained in Section 8.3 for character strings).

## 8.11. Text Search Types

PostgreSQL provides two data types that are designed to support full text search, which is the activity of searching through a collection of natural-language *documents* to locate those that best match a *query*. The `tsvector` type represents a document in a form suited for text search, while the `tsquery` type similarly represents a query. Chapter 12 provides a detailed explanation of this facility, and Section 9.13 summarizes the related functions and operators.

### 8.11.1. `tsvector`

A `tsvector` value is a sorted list of distinct *lexemes*, which are words that have been *normalized* to make different variants of the same word look alike (see Chapter 12 for details). Sorting and duplicate-elimination are done automatically during input, as shown in this example:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
               tsvector
-----
'a' 'on' 'and' 'ate' 'cat' 'fat' 'mat' 'rat' 'sat'
```

(As the example shows, the sorting is first by length and then alphabetically, but that detail is seldom important.) To represent lexemes containing whitespace or punctuation, surround them with quotes:

```
SELECT $$the lexeme '    ' contains spaces$$::tsvector;
```

```

                                tsvector
-----
'the' ' ' 'lexeme' 'spaces' 'contains'

```

(We use dollar-quoted string literals in this example and the next one, to avoid confusing matters by having to double quote marks within the literals.) Embedded quotes and backslashes must be doubled:

```

SELECT $$the lexeme 'Joe"s' contains a quote$$::tsvector;
                                tsvector
-----
'a' 'the' 'Joe"s' 'quote' 'lexeme' 'contains'

```

Optionally, integer *position(s)* can be attached to any or all of the lexemes:

```

SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;
                                tsvector
-----
'a':1,6,10 'on':5 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4

```

A position normally indicates the source word's location in the document. Positional information can be used for *proximity ranking*. Position values can range from 1 to 16383; larger numbers are silently clamped to 16383. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a *weight*, which can be A, B, C, or D. D is the default and hence is not shown on output:

```

SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;
                                tsvector
-----
'a':1A 'cat':5 'fat':2B,4C

```

Weights are typically used to reflect document structure, for example by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.

It is important to understand that the `tsvector` type itself does not perform any normalization; it assumes that the words it is given are normalized appropriately for the application. For example,

```

select 'The Fat Rats'::tsvector;
                                tsvector
-----
'Fat' 'The' 'Rats'

```

For most English-text-searching applications the above words would be considered non-normalized, but `tsvector` doesn't care. Raw document text should usually be passed through `to_tsvector` to normalize the words appropriately for searching:

```

SELECT to_tsvector('english', 'The Fat Rats');
                                to_tsvector
-----
'fat':2 'rat':3

```

Again, see Chapter 12 for more detail.

### 8.11.2. tsquery

A `tsquery` value stores lexemes that are to be searched for, and combines them using the boolean operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used to enforce grouping of the operators:

```
SELECT 'fat & rat'::tsquery;
      tsquery
-----
'fat' & 'rat'

SELECT 'fat & (rat | cat)'::tsquery;
      tsquery
-----
'fat' & ( 'rat' | 'cat' )

SELECT 'fat & rat & ! cat'::tsquery;
      tsquery
-----
'fat' & 'rat' & !'cat'
```

In the absence of parentheses, `!` (NOT) binds most tightly, and `&` (AND) binds more tightly than `|` (OR).

Optionally, lexemes in a `tsquery` can be labeled with one or more weight letters, which restricts them to match only `tsvector` lexemes with one of those weights:

```
SELECT 'fat:ab & cat'::tsquery;
      tsquery
-----
'fat':AB & 'cat'
```

Quoting rules for lexemes are the same as described above for lexemes in `tsvector`; and, as with `tsvector`, any required normalization of words must be done before putting them into the `tsquery` type. The `to_tsquery` function is convenient for performing such normalization:

```
SELECT to_tsquery('Fat:ab & Cats');
      to_tsquery
-----
'fat':AB & 'cat'
```

## 8.12. UUID Type

The data type `uuid` stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEC 9834-8:2005, and related standards. (Some systems refer to this data type as globally unique identifier, or GUID, instead.) Such an identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm. Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than that which can be achieved using sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

PostgreSQL also accepts the following alternative forms for input: use of upper-case digits, the standard format surrounded by braces, and omitting the hyphens. Examples are:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
```

Output is always in the standard form.

PostgreSQL provides storage and comparison functions for UUIDs, but the core database does not include any function for generating UUIDs, because no single algorithm is well suited for every application. The contrib module `contrib/uuid-oss` provides functions that implement several standard algorithms. Alternatively, UUIDs could be generated by client applications or other libraries invoked through a server-side function.

## 8.13. XML Type

The data type `xml` can be used to store XML data. Its advantage over storing XML data in a `text` field is that it checks the input values for well-formedness, and there are support functions to perform type-safe operations on it; see Section 9.14. Use of this data type requires the installation to have been built with `configure --with-libxml`.

The `xml` type can store well-formed “documents”, as defined by the XML standard, as well as “content” fragments, which are defined by the production `XMLDecl? content` in the XML standard. Roughly, this means that content fragments can have more than one top-level element or character node. The expression `xmlvalue IS DOCUMENT` can be used to evaluate whether a particular `xml` value is a full document or only a content fragment.

### 8.13.1. Creating XML Values

To produce a value of type `xml` from character data, use the function `xmlparse`:

```
XMLPARSE ( { DOCUMENT | CONTENT } value)
```

Examples:

```
XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter><
XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>')
```

While this is the only way to convert character strings into XML values according to the SQL standard, the PostgreSQL-specific syntaxes:

```
xml '<foo>bar</foo>'
'<foo>bar</foo>'::xml
```

can also be used.

The `xml` type does not validate its input values against a possibly included document type declaration (DTD).

The inverse operation, producing character string type values from `xml`, uses the function `xmlserialize`:

```
XMLSERIALIZE ( { DOCUMENT | CONTENT } value AS type )
```

`type` can be one of `character`, `character varying`, or `text` (or an alias name for those). Again, according to the SQL standard, this is the only way to convert between type `xml` and character types, but PostgreSQL also allows you to simply cast the value.

When character string values are cast to or from type `xml` without going through `XMLPARSE` or `XMLSERIALIZE`, respectively, the choice of `DOCUMENT` versus `CONTENT` is determined by the “XML option” session configuration parameter, which can be set using the standard command

```
SET XML OPTION { DOCUMENT | CONTENT };
```

or the more PostgreSQL-like syntax

```
SET xmloption TO { DOCUMENT | CONTENT };
```

The default is `CONTENT`, so all forms of XML data are allowed.

### 8.13.2. Encoding Handling

Care must be taken when dealing with multiple character encodings on the client, server, and in the XML data passed through them. When using the text mode to pass queries to the server and query results to the client (which is the normal mode), PostgreSQL converts all character data passed between the client and the server and vice versa to the character encoding of the respective end; see Section 22.2. This includes string representations of XML values, such as in the above examples. This would ordinarily mean that encoding declarations contained in XML data might become invalid as the character data is converted to other encodings while travelling between client and server, while the embedded encoding declaration is not changed. To cope with this behavior, an encoding declaration contained in a character string presented for input to the `xml` type is *ignored*, and the content is always assumed to be in the current server encoding. Consequently, for correct processing, such character strings of XML data must be sent off from the client in the current client encoding. It is the responsibility of the client to either convert the document to the current client encoding before sending it off to the server or to adjust the client encoding appropriately. On output, values of type `xml` will not have an encoding declaration, and clients must assume that the data is in the current client encoding.

When using the binary mode to pass query parameters to the server and query results back to the client, no character set conversion is performed, so the situation is different. In this case, an encoding declaration in the XML data will be observed, and if it is absent, the data will be assumed to be in UTF-8 (as required by the XML standard; note that PostgreSQL does not support UTF-16 at all). On output, data will have an encoding declaration specifying the client encoding, unless the client encoding is UTF-8, in which case it will be omitted.

Needless to say, processing XML data with PostgreSQL will be less error-prone and more efficient if data encoding, client encoding, and server encoding are the same. Since XML data is internally processed in UTF-8, computations will be most efficient if the server encoding is also UTF-8.

### 8.13.3. Accessing XML Values

The `xml` data type is unusual in that it does not provide any comparison operators. This is because there is no well-defined and universally useful comparison algorithm for XML data. One consequence of this is that you cannot retrieve rows by comparing an `xml` column against a search value. XML values should therefore typically be accompanied by a separate key field such as an ID. An alternative solution for comparing XML values is to convert them to character strings first, but note that character string comparison has little to do with a useful XML comparison method.

Since there are no comparison operators for the `xml` data type, it is not possible to create an index directly on a column of this type. If speedy searches in XML data are desired, possible workarounds would be casting the expression to a character string type and indexing that, or indexing an XPath expression. The actual query would of course have to be adjusted to search by the indexed expression.

The text-search functionality in PostgreSQL could also be used to speed up full-document searches in XML data. The necessary preprocessing support is, however, not available in the PostgreSQL distribution in this release.

## 8.14. Arrays

PostgreSQL allows columns of a table to be defined as variable-length multidimensional arrays. Arrays of any built-in or user-defined base type, enum type, or composite type can be created. Arrays of domains are not yet supported.

### 8.14.1. Declaration of Array Types

To illustrate the use of array types, we create this table:

```
CREATE TABLE sal_emp (
    name            text,
    pay_by_quarter  integer[],
    schedule        text[][]
);
```

As shown, an array data type is named by appending square brackets (`[]`) to the data type name of the array elements. The above command will create a table named `sal_emp` with a column of type `text` (`name`), a one-dimensional array of type `integer` (`pay_by_quarter`), which represents the employee's salary by quarter, and a two-dimensional array of `text` (`schedule`), which represents the employee's weekly schedule.

The syntax for `CREATE TABLE` allows the exact size of arrays to be specified, for example:

```
CREATE TABLE tictactoe (
    squares        integer[3][3]
);
```

However, the current implementation does not enforce the array size limits — the behavior is the same as for arrays of unspecified length.

Actually, the current implementation does not enforce the declared number of dimensions either. Arrays of a particular element type are all considered to be of the same type, regardless of size or number of dimensions. So, declaring number of dimensions or sizes in `CREATE TABLE` is simply documentation, it does not affect run-time behavior.

An alternative syntax, which conforms to the SQL standard, can be used for one-dimensional arrays. `pay_by_quarter` could have been defined as:

```
pay_by_quarter integer ARRAY[4],
```

This syntax requires an integer constant to denote the array size. As before, however, PostgreSQL does not enforce the size restriction.

### 8.14.2. Array Value Input

To write an array value as a literal constant, enclose the element values within curly braces and separate them by commas. (If you know C, this is not unlike the C syntax for initializing structures.) You can put double quotes around any element value, and must do so if it contains commas or curly braces. (More details appear below.) Thus, the general format of an array constant is the following:

```
'{ val1 delim val2 delim ... }'
```

where *delim* is the delimiter character for the type, as recorded in its `pg_type` entry. Among the standard data types provided in the PostgreSQL distribution, type `box` uses a semicolon (;) but all the others use comma (,). Each *val* is either a constant of the array element type, or a subarray. An example of an array constant is:

```
'{{1,2,3},{4,5,6},{7,8,9}}'
```

This constant is a two-dimensional, 3-by-3 array consisting of three subarrays of integers.

To set an element of an array constant to `NULL`, write `NULL` for the element value. (Any upper- or lower-case variant of `NULL` will do.) If you want an actual string value “NULL”, you must put double quotes around it.

(These kinds of array constants are actually only a special case of the generic type constants discussed in Section 4.1.2.5. The constant is initially treated as a string and passed to the array input conversion routine. An explicit type specification might be necessary.)

Now we can show some `INSERT` statements:

```
INSERT INTO sal_emp
VALUES ('Bill',
       '{10000, 10000, 10000, 10000}',
       '{{"meeting", "lunch"}, {"training", "presentation"}}');
```

```
INSERT INTO sal_emp
VALUES ('Carol',
       '{20000, 25000, 25000, 25000}',
       '{{"breakfast", "consulting"}, {"meeting", "lunch"}}');
```

The result of the previous two inserts looks like this:

```
SELECT * FROM sal_emp;
  name |          pay_by_quarter          |          schedule
-----+-----+-----
  Bill | {10000,10000,10000,10000} | {{meeting,lunch},{training,presentation}}
  Carol | {20000,25000,25000,25000} | {{breakfast,consulting},{meeting,lunch}}
(2 rows)
```

The ARRAY constructor syntax can also be used:

```
INSERT INTO sal_emp
VALUES ('Bill',
ARRAY[10000, 10000, 10000, 10000],
ARRAY[['meeting', 'lunch'], ['training', 'presentation']]);

INSERT INTO sal_emp
VALUES ('Carol',
ARRAY[20000, 25000, 25000, 25000],
ARRAY[['breakfast', 'consulting'], ['meeting', 'lunch']]);
```

Notice that the array elements are ordinary SQL constants or expressions; for instance, string literals are single quoted, instead of double quoted as they would be in an array literal. The ARRAY constructor syntax is discussed in more detail in Section 4.2.10.

Multidimensional arrays must have matching extents for each dimension. A mismatch causes an error report, for example:

```
INSERT INTO sal_emp
VALUES ('Bill',
' {10000, 10000, 10000, 10000}',
'{{"meeting", "lunch"}, {"meeting"}}');
ERROR: multidimensional arrays must have array expressions with matching dimensions
```

### 8.14.3. Accessing Arrays

Now, we can run some queries on the table. First, we show how to access a single element of an array at a time. This query retrieves the names of the employees whose pay changed in the second quarter:

```
SELECT name FROM sal_emp WHERE pay_by_quarter[1] <> pay_by_quarter[2];

 name
-----
  Carol
(1 row)
```

The array subscript numbers are written within square brackets. By default PostgreSQL uses the one-based numbering convention for arrays, that is, an array of  $n$  elements starts with `array[1]` and ends with `array[n]`.

This query retrieves the third quarter pay of all employees:

```
SELECT pay_by_quarter[3] FROM sal_emp;
```

```
pay_by_quarter
-----
          10000
          25000
(2 rows)
```

We can also access arbitrary rectangular slices of an array, or subarrays. An array slice is denoted by writing *lower-bound:upper-bound* for one or more array dimensions. For example, this query retrieves the first item on Bill's schedule for the first two days of the week:

```
SELECT schedule[1:2][1:1] FROM sal_emp WHERE name = 'Bill';
```

```
schedule
-----
{{meeting},{training}}
(1 row)
```

If any dimension is written as a slice, i.e. contains a colon, then all dimensions are treated as slices. Any dimension that has only a single number (no colon) is treated as being from 1 to the number specified. For example, `[2]` is treated as `[1:2]`, as in this example:

```
SELECT schedule[1:2][2] FROM sal_emp WHERE name = 'Bill';
```

```
schedule
-----
{{meeting,lunch},{training,presentation}}
(1 row)
```

An array subscript expression will return null if either the array itself or any of the subscript expressions are null. Also, null is returned if a subscript is outside the array bounds (this case does not raise an error). For example, if `schedule` currently has the dimensions `[1:3][1:2]` then referencing `schedule[3][3]` yields NULL. Similarly, an array reference with the wrong number of subscripts yields a null rather than an error.

An array slice expression likewise yields null if the array itself or any of the subscript expressions are null. However, in other corner cases such as selecting an array slice that is completely outside the current array bounds, a slice expression yields an empty (zero-dimensional) array instead of null. If the requested slice partially overlaps the array bounds, then it is silently reduced to just the overlapping region.

The current dimensions of any array value can be retrieved with the `array_dims` function:

```
SELECT array_dims(schedule) FROM sal_emp WHERE name = 'Carol';
```

```

array_dims
-----
[1:2][1:2]
(1 row)

```

`array_dims` produces a text result, which is convenient for people to read but perhaps not so convenient for programs. Dimensions can also be retrieved with `array_upper` and `array_lower`, which return the upper and lower bound of a specified array dimension, respectively:

```
SELECT array_upper(schedule, 1) FROM sal_emp WHERE name = 'Carol';
```

```

array_upper
-----
                2
(1 row)

```

### 8.14.4. Modifying Arrays

An array value can be replaced completely:

```
UPDATE sal_emp SET pay_by_quarter = '{25000,25000,27000,27000}'
WHERE name = 'Carol';
```

or using the `ARRAY` expression syntax:

```
UPDATE sal_emp SET pay_by_quarter = ARRAY[25000,25000,27000,27000]
WHERE name = 'Carol';
```

An array can also be updated at a single element:

```
UPDATE sal_emp SET pay_by_quarter[4] = 15000
WHERE name = 'Bill';
```

or updated in a slice:

```
UPDATE sal_emp SET pay_by_quarter[1:2] = '{27000,27000}'
WHERE name = 'Carol';
```

A stored array value can be enlarged by assigning to element(s) not already present. Any positions between those previously present and the newly assigned element(s) will be filled with nulls. For example, if array `myarray` currently has 4 elements, it will have six elements after an update that assigns to `myarray[6]`, and `myarray[5]` will contain a null. Currently, enlargement in this fashion is only allowed for one-dimensional arrays, not multidimensional arrays.

Subscripted assignment allows creation of arrays that do not use one-based subscripts. For example one might assign to `myarray[-2:7]` to create an array with subscript values running from -2 to 7.

New array values can also be constructed by using the concatenation operator, `||`:

```

SELECT ARRAY[1,2] || ARRAY[3,4];
      ?column?
-----
      {1,2,3,4}
(1 row)

SELECT ARRAY[5,6] || ARRAY[[1,2],[3,4]];
      ?column?
-----
      {{5,6},{1,2},{3,4}}
(1 row)

```

The concatenation operator allows a single element to be pushed on to the beginning or end of a one-dimensional array. It also accepts two  $N$ -dimensional arrays, or an  $N$ -dimensional and an  $N+1$ -dimensional array.

When a single element is pushed on to either the beginning or end of a one-dimensional array, the result is an array with the same lower bound subscript as the array operand. For example:

```

SELECT array_dims(1 || '[0:1]={2,3}':int[]);
      array_dims
-----
      [0:2]
(1 row)

SELECT array_dims(ARRAY[1,2] || 3);
      array_dims
-----
      [1:3]
(1 row)

```

When two arrays with an equal number of dimensions are concatenated, the result retains the lower bound subscript of the left-hand operand's outer dimension. The result is an array comprising every element of the left-hand operand followed by every element of the right-hand operand. For example:

```

SELECT array_dims(ARRAY[1,2] || ARRAY[3,4,5]);
      array_dims
-----
      [1:5]
(1 row)

SELECT array_dims(ARRAY[[1,2],[3,4]] || ARRAY[[5,6],[7,8],[9,0]]);
      array_dims
-----
      [1:5][1:2]
(1 row)

```

When an  $N$ -dimensional array is pushed on to the beginning or end of an  $N+1$ -dimensional array, the result is analogous to the element-array case above. Each  $N$ -dimensional sub-array is essentially an element of the  $N+1$ -dimensional array's outer dimension. For example:

```
SELECT array_dims (ARRAY[1,2] || ARRAY[[3,4],[5,6]]);
 array_dims
-----
 [1:3][1:2]
(1 row)
```

An array can also be constructed by using the functions `array_prepend`, `array_append`, or `array_cat`. The first two only support one-dimensional arrays, but `array_cat` supports multidimensional arrays. Note that the concatenation operator discussed above is preferred over direct use of these functions. In fact, the functions exist primarily for use in implementing the concatenation operator. However, they might be directly useful in the creation of user-defined aggregates. Some examples:

```
SELECT array_prepend(1, ARRAY[2,3]);
 array_prepend
-----
 {1,2,3}
(1 row)

SELECT array_append(ARRAY[1,2], 3);
 array_append
-----
 {1,2,3}
(1 row)

SELECT array_cat(ARRAY[1,2], ARRAY[3,4]);
 array_cat
-----
 {1,2,3,4}
(1 row)

SELECT array_cat(ARRAY[[1,2],[3,4]], ARRAY[5,6]);
 array_cat
-----
 {{1,2},{3,4},{5,6}}
(1 row)

SELECT array_cat(ARRAY[5,6], ARRAY[[1,2],[3,4]]);
 array_cat
-----
 {{5,6},{1,2},{3,4}}
```

### 8.14.5. Searching in Arrays

To search for a value in an array, you must check each value of the array. This can be done by hand, if you know the size of the array. For example:

```
SELECT * FROM sal_emp WHERE pay_by_quarter[1] = 10000 OR
                           pay_by_quarter[2] = 10000 OR
                           pay_by_quarter[3] = 10000 OR
                           pay_by_quarter[4] = 10000;
```

However, this quickly becomes tedious for large arrays, and is not helpful if the size of the array is uncertain. An alternative method is described in Section 9.20. The above query could be replaced by:

```
SELECT * FROM sal_emp WHERE 10000 = ANY (pay_by_quarter);
```

In addition, you could find rows where the array had all values equal to 10000 with:

```
SELECT * FROM sal_emp WHERE 10000 = ALL (pay_by_quarter);
```

**Tip:** Arrays are not sets; searching for specific array elements can be a sign of database misdesign. Consider using a separate table with a row for each item that would be an array element. This will be easier to search, and is likely to scale up better to large numbers of elements.

### 8.14.6. Array Input and Output Syntax

The external text representation of an array value consists of items that are interpreted according to the I/O conversion rules for the array's element type, plus decoration that indicates the array structure. The decoration consists of curly braces (`{` and `}`) around the array value plus delimiter characters between adjacent items. The delimiter character is usually a comma (`,`) but can be something else: it is determined by the `typdelim` setting for the array's element type. (Among the standard data types provided in the PostgreSQL distribution, type `box` uses a semicolon (`;`) but all the others use comma.) In a multidimensional array, each dimension (row, plane, cube, etc.) gets its own level of curly braces, and delimiters must be written between adjacent curly-braced entities of the same level.

The array output routine will put double quotes around element values if they are empty strings, contain curly braces, delimiter characters, double quotes, backslashes, or white space, or match the word `NULL`. Double quotes and backslashes embedded in element values will be backslash-escaped. For numeric data types it is safe to assume that double quotes will never appear, but for textual data types one should be prepared to cope with either presence or absence of quotes.

By default, the lower bound index value of an array's dimensions is set to one. To represent arrays with other lower bounds, the array subscript ranges can be specified explicitly before writing the array contents. This decoration consists of square brackets (`[]`) around each array dimension's lower and upper bounds, with a colon (`:`) delimiter character in between. The array dimension decoration is followed by an equal sign (`=`). For example:

```
SELECT f1[1][-2][3] AS e1, f1[1][-1][5] AS e2
```

```

FROM (SELECT ' [1:1] [-2:-1] [3:5]={{{1,2,3},{4,5,6}}}'::int[] AS f1) AS ss;

 e1 | e2
-----+-----
   1 |    6
(1 row)

```

The array output routine will include explicit dimensions in its result only when there are one or more lower bounds different from one.

If the value written for an element is `NULL` (in any case variant), the element is taken to be `NULL`. The presence of any quotes or backslashes disables this and allows the literal string value “`NULL`” to be entered. Also, for backwards compatibility with pre-8.2 versions of PostgreSQL, the `array_nulls` configuration parameter might be turned `off` to suppress recognition of `NULL` as a `NULL`.

As shown previously, when writing an array value you can write double quotes around any individual array element. You *must* do so if the element value would otherwise confuse the array-value parser. For example, elements containing curly braces, commas (or whatever the delimiter character is), double quotes, backslashes, or leading or trailing whitespace must be double-quoted. Empty strings and strings matching the word `NULL` must be quoted, too. To put a double quote or backslash in a quoted array element value, use escape string syntax and precede it with a backslash. Alternatively, you can use backslash-escaping to protect all data characters that would otherwise be taken as array syntax.

You can write whitespace before a left brace or after a right brace. You can also write whitespace before or after any individual item string. In all of these cases the whitespace will be ignored. However, whitespace within double-quoted elements, or surrounded on both sides by non-whitespace characters of an element, is not ignored.

**Note:** Remember that what you write in an SQL command will first be interpreted as a string literal, and then as an array. This doubles the number of backslashes you need. For example, to insert a `text` array value containing a backslash and a double quote, you’d need to write:

```
INSERT ... VALUES (E' {"\\", "\""}');
```

The escape string processor removes one level of backslashes, so that what arrives at the array-value parser looks like `{"\\", "\""}`. In turn, the strings fed to the `text` data type’s input routine become `\` and `"` respectively. (If we were working with a data type whose input routine also treated backslashes specially, `bytea` for example, we might need as many as eight backslashes in the command to get one backslash into the stored array element.) Dollar quoting (see Section 4.1.2.2) can be used to avoid the need to double backslashes.

**Tip:** The `ARRAY` constructor syntax (see Section 4.2.10) is often easier to work with than the array-literal syntax when writing array values in SQL commands. In `ARRAY`, individual element values are written the same way they would be written when not members of an array.

## 8.15. Composite Types

A *composite type* describes the structure of a row or record; it is in essence just a list of field names and their data types. PostgreSQL allows values of composite types to be used in many of the same ways that simple types can be used. For example, a column of a table can be declared to be of a composite type.

### 8.15.1. Declaration of Composite Types

Here are two simple examples of defining composite types:

```
CREATE TYPE complex AS (
    r      double precision,
    i      double precision
);

CREATE TYPE inventory_item AS (
    name          text,
    supplier_id   integer,
    price         numeric
);
```

The syntax is comparable to `CREATE TABLE`, except that only field names and types can be specified; no constraints (such as `NOT NULL`) can presently be included. Note that the `AS` keyword is essential; without it, the system will think a quite different kind of `CREATE TYPE` command is meant, and you'll get odd syntax errors.

Having defined the types, we can use them to create tables:

```
CREATE TABLE on_hand (
    item      inventory_item,
    count     integer
);

INSERT INTO on_hand VALUES (ROW('fuzzy dice', 42, 1.99), 1000);
```

or functions:

```
CREATE FUNCTION price_extension(inventory_item, integer) RETURNS numeric
AS 'SELECT $1.price * $2' LANGUAGE SQL;

SELECT price_extension(item, 10) FROM on_hand;
```

Whenever you create a table, a composite type is also automatically created, with the same name as the table, to represent the table's row type. For example, had we said:

```
CREATE TABLE inventory_item (
    name          text,
    supplier_id   integer REFERENCES suppliers,
    price         numeric CHECK (price > 0)
);
```

then the same `inventory_item` composite type shown above would come into being as a byproduct, and could be used just as above. Note however an important restriction of the current implementation: since no constraints are associated with a composite type, the constraints shown in the table definition *do not apply* to values of the composite type outside the table. (A partial workaround is to use domain types as members of composite types.)

### 8.15.2. Composite Value Input

To write a composite value as a literal constant, enclose the field values within parentheses and separate them by commas. You can put double quotes around any field value, and must do so if it contains commas or parentheses. (More details appear below.) Thus, the general format of a composite constant is the following:

```
' ( val1 , val2 , ... ) '
```

An example is:

```
' ("fuzzy dice", 42, 1.99) '
```

which would be a valid value of the `inventory_item` type defined above. To make a field be NULL, write no characters at all in its position in the list. For example, this constant specifies a NULL third field:

```
' ("fuzzy dice", 42, ) '
```

If you want an empty string rather than NULL, write double quotes:

```
' ("", 42, ) '
```

Here the first field is a non-NULL empty string, the third is NULL.

(These constants are actually only a special case of the generic type constants discussed in Section 4.1.2.5. The constant is initially treated as a string and passed to the composite-type input conversion routine. An explicit type specification might be necessary.)

The ROW expression syntax can also be used to construct composite values. In most cases this is considerably simpler to use than the string-literal syntax, since you don't have to worry about multiple layers of quoting. We already used this method above:

```
ROW('fuzzy dice', 42, 1.99)
ROW("", 42, NULL)
```

The ROW keyword is actually optional as long as you have more than one field in the expression, so these can simplify to:

```
('fuzzy dice', 42, 1.99)
("", 42, NULL)
```

The ROW expression syntax is discussed in more detail in Section 4.2.11.

### 8.15.3. Accessing Composite Types

To access a field of a composite column, one writes a dot and the field name, much like selecting a field from a table name. In fact, it's so much like selecting from a table name that you often have to use parentheses to keep from confusing the parser. For example, you might try to select some subfields from our `on_hand` example table with something like:

```
SELECT item.name FROM on_hand WHERE item.price > 9.99;
```

This will not work since the name `item` is taken to be a table name, not a field name, per SQL syntax rules. You must write it like this:

```
SELECT (item).name FROM on_hand WHERE (item).price > 9.99;
```

or if you need to use the table name as well (for instance in a multitable query), like this:

```
SELECT (on_hand.item).name FROM on_hand WHERE (on_hand.item).price > 9.99;
```

Now the parenthesized object is correctly interpreted as a reference to the `item` column, and then the subfield can be selected from it.

Similar syntactic issues apply whenever you select a field from a composite value. For instance, to select just one field from the result of a function that returns a composite value, you'd need to write something like:

```
SELECT (my_func(...)).field FROM ...
```

Without the extra parentheses, this will provoke a syntax error.

### 8.15.4. Modifying Composite Types

Here are some examples of the proper syntax for inserting and updating composite columns. First, inserting or updating a whole column:

```
INSERT INTO mytab (complex_col) VALUES ((1.1,2.2));
```

```
UPDATE mytab SET complex_col = ROW(1.1,2.2) WHERE ...;
```

The first example omits `ROW`, the second uses it; we could have done it either way.

We can update an individual subfield of a composite column:

```
UPDATE mytab SET complex_col.r = (complex_col).r + 1 WHERE ...;
```

Notice here that we don't need to (and indeed cannot) put parentheses around the column name appearing just after `SET`, but we do need parentheses when referencing the same column in the expression to the right of the equal sign.

And we can specify subfields as targets for `INSERT`, too:

```
INSERT INTO mytab (complex_col.r, complex_col.i) VALUES(1.1, 2.2);
```

Had we not supplied values for all the subfields of the column, the remaining subfields would have been filled with null values.

### 8.15.5. Composite Type Input and Output Syntax

The external text representation of a composite value consists of items that are interpreted according to the I/O conversion rules for the individual field types, plus decoration that indicates the composite structure. The decoration consists of parentheses ( ( and ) ) around the whole value, plus commas ( , ) between adjacent items. Whitespace outside the parentheses is ignored, but within the parentheses it is considered part of the field value, and might or might not be significant depending on the input conversion rules for the field data type. For example, in:

```
' ( 42 ) '
```

the whitespace will be ignored if the field type is integer, but not if it is text.

As shown previously, when writing a composite value you can write double quotes around any individual field value. You *must* do so if the field value would otherwise confuse the composite-value parser. In particular, fields containing parentheses, commas, double quotes, or backslashes must be double-quoted. To put a double quote or backslash in a quoted composite field value, precede it with a backslash. (Also, a pair of double quotes within a double-quoted field value is taken to represent a double quote character, analogously to the rules for single quotes in SQL literal strings.) Alternatively, you can use backslash-escaping to protect all data characters that would otherwise be taken as composite syntax.

A completely empty field value (no characters at all between the commas or parentheses) represents a NULL. To write a value that is an empty string rather than NULL, write "".

The composite output routine will put double quotes around field values if they are empty strings or contain parentheses, commas, double quotes, backslashes, or white space. (Doing so for white space is not essential, but aids legibility.) Double quotes and backslashes embedded in field values will be doubled.

**Note:** Remember that what you write in an SQL command will first be interpreted as a string literal, and then as a composite. This doubles the number of backslashes you need (assuming escape string syntax is used). For example, to insert a `text` field containing a double quote and a backslash in a composite value, you'd need to write:

```
INSERT ... VALUES (E'("\\\\"\\")');
```

The string-literal processor removes one level of backslashes, so that what arrives at the composite-value parser looks like ("\\"). In turn, the string fed to the `text` data type's input routine becomes "\. (If we were working with a data type whose input routine also treated backslashes specially, `bytea` for example, we might need as many as eight backslashes in the command to get one backslash into the stored composite field.) Dollar quoting (see Section 4.1.2.2) can be used to avoid the need to double backslashes.

**Tip:** The `ROW` constructor syntax is usually easier to work with than the composite-literal syntax when writing composite values in SQL commands. In `ROW`, individual field values are written the same way they would be written when not members of a composite.

## 8.16. Object Identifier Types

Object identifiers (OIDs) are used internally by PostgreSQL as primary keys for various system tables. OIDs are not added to user-created tables, unless `WITH OIDS` is specified when the table is created, or the `default_with_oids` configuration variable is enabled. Type `oid` represents an object identifier. There are also several alias types for `oid`: `regproc`, `regprocedure`, `regoper`, `regoperator`, `regclass`, `regtype`, `regconfig`, and `regdictionary`. Table 8-19 shows an overview.

The `oid` type is currently implemented as an unsigned four-byte integer. Therefore, it is not large enough to provide database-wide uniqueness in large databases, or even in large individual tables. So, using a user-created table's OID column as a primary key is discouraged. OIDs are best used only for references to system tables.

The `oid` type itself has few operations beyond comparison. It can be cast to integer, however, and then manipulated using the standard integer operators. (Beware of possible signed-versus-unsigned confusion if you do this.)

The OID alias types have no operations of their own except for specialized input and output routines. These routines are able to accept and display symbolic names for system objects, rather than the raw numeric value that type `oid` would use. The alias types allow simplified lookup of OID values for objects. For example, to examine the `pg_attribute` rows related to a table `mytable`, one could write:

```
SELECT * FROM pg_attribute WHERE attrelid = 'mytable'::regclass;
```

rather than:

```
SELECT * FROM pg_attribute
  WHERE attrelid = (SELECT oid FROM pg_class WHERE relname = 'mytable');
```

While that doesn't look all that bad by itself, it's still oversimplified. A far more complicated sub-select would be needed to select the right OID if there are multiple tables named `mytable` in different schemas. The `regclass` input converter handles the table lookup according to the schema path setting, and so it does the "right thing" automatically. Similarly, casting a table's OID to `regclass` is handy for symbolic display of a numeric OID.

**Table 8-19. Object Identifier Types**

Name	References	Description	Value Example
<code>oid</code>	any	numeric object identifier	564182
<code>regproc</code>	<code>pg_proc</code>	function name	<code>sum</code>
<code>regprocedure</code>	<code>pg_proc</code>	function with argument types	<code>sum(int4)</code>
<code>regoper</code>	<code>pg_operator</code>	operator name	<code>+</code>
<code>regoperator</code>	<code>pg_operator</code>	operator with argument types	<code>*(integer, integer)</code> or <code>-(NONE, integer)</code>
<code>regclass</code>	<code>pg_class</code>	relation name	<code>pg_type</code>
<code>regtype</code>	<code>pg_type</code>	data type name	<code>integer</code>

Name	References	Description	Value Example
<code>regconfig</code>	<code>pg_ts_config</code>	text search configuration	<code>english</code>
<code>regdictionary</code>	<code>pg_ts_dict</code>	text search dictionary	<code>simple</code>

All of the OID alias types accept schema-qualified names, and will display schema-qualified names on output if the object would not be found in the current search path without being qualified. The `regproc` and `regoper` alias types will only accept input names that are unique (not overloaded), so they are of limited use; for most uses `regprocedure` or `regoperator` is more appropriate. For `regoperator`, unary operators are identified by writing `NONE` for the unused operand.

An additional property of the OID alias types is that if a constant of one of these types appears in a stored expression (such as a column default expression or view), it creates a dependency on the referenced object. For example, if a column has a default expression `nextval('my_seq'::regclass)`, PostgreSQL understands that the default expression depends on the sequence `my_seq`; the system will not let the sequence be dropped without first removing the default expression.

Another identifier type used by the system is `xid`, or transaction (abbreviated `xact`) identifier. This is the data type of the system columns `xmin` and `xmax`. Transaction identifiers are 32-bit quantities.

A third identifier type used by the system is `cid`, or command identifier. This is the data type of the system columns `cmin` and `cmax`. Command identifiers are also 32-bit quantities.

A final identifier type used by the system is `tid`, or tuple identifier (row identifier). This is the data type of the system column `ctid`. A tuple ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.

(The system columns are further explained in Section 5.4.)

## 8.17. Pseudo-Types

The PostgreSQL type system contains a number of special-purpose entries that are collectively called *pseudo-types*. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type. Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. Table 8-20 lists the existing pseudo-types.

**Table 8-20. Pseudo-Types**

Name	Description
<code>any</code>	Indicates that a function accepts any input data type whatever.
<code>anyarray</code>	Indicates that a function accepts any array data type (see Section 34.2.5).
<code>anyelement</code>	Indicates that a function accepts any data type (see Section 34.2.5).
<code>anyenum</code>	Indicates that a function accepts any enum data type (see Section 34.2.5 and Section 8.7).

Name	Description
<code>anynonarray</code>	Indicates that a function accepts any non-array data type (see Section 34.2.5).
<code>cstring</code>	Indicates that a function accepts or returns a null-terminated C string.
<code>internal</code>	Indicates that a function accepts or returns a server-internal data type.
<code>language_handler</code>	A procedural language call handler is declared to return <code>language_handler</code> .
<code>record</code>	Identifies a function returning an unspecified row type.
<code>trigger</code>	A trigger function is declared to return <code>trigger</code> .
<code>void</code>	Indicates that a function returns no value.
<code>opaque</code>	An obsolete type name that formerly served all the above purposes.

Functions coded in C (whether built-in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only `void` and `record` as a result type (plus `trigger` when the function is used as a trigger). Some also support polymorphic functions using the types `anyarray`, `anyelement`, `anyenum`, and `anynonarray`.

The `internal` pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct invocation in a SQL query. If a function has at least one `internal`-type argument then it cannot be called from SQL. To preserve the type safety of this restriction it is important to follow this coding rule: do not create any function that is declared to return `internal` unless it has at least one `internal` argument.

# Chapter 9. Functions and Operators

PostgreSQL provides a large number of functions and operators for the built-in data types. Users can also define their own functions and operators, as described in Part V. The `psql` commands `\df` and `\do` can be used to show the list of all actually available functions and operators, respectively.

If you are concerned about portability then take note that most of the functions and operators described in this chapter, with the exception of the most trivial arithmetic and comparison operators and some explicitly marked functions, are not specified by the SQL standard. Some of the extended functionality is present in other SQL database management systems, and in many cases this functionality is compatible and consistent between the various implementations. This chapter is also not exhaustive; additional functions appear in relevant sections of the manual.

## 9.1. Logical Operators

The usual logical operators are available:

AND  
OR  
NOT

SQL uses a three-valued Boolean logic where the null value represents “unknown”. Observe the following truth tables:

<b>a</b>	<b>b</b>	<b>a AND b</b>	<b>a OR b</b>
TRUE	TRUE	TRUE	TRUE
TRUE	FALSE	FALSE	TRUE
TRUE	NULL	NULL	TRUE
FALSE	FALSE	FALSE	FALSE
FALSE	NULL	FALSE	NULL
NULL	NULL	NULL	NULL

<b>a</b>	<b>NOT a</b>
TRUE	FALSE
FALSE	TRUE
NULL	NULL

The operators `AND` and `OR` are commutative, that is, you can switch the left and right operand without affecting the result. But see Section 4.2.12 for more information about the order of evaluation of subexpressions.

## 9.2. Comparison Operators

The usual comparison operators are available, shown in Table 9-1.

**Table 9-1. Comparison Operators**

Operator	Description
<	less than
>	greater than
<=	less than or equal to
>=	greater than or equal to
=	equal
<> or !=	not equal

**Note:** The != operator is converted to <> in the parser stage. It is not possible to implement != and <> operators that do different things.

Comparison operators are available for all data types where this makes sense. All comparison operators are binary operators that return values of type `boolean`; expressions like `1 < 2 < 3` are not valid (because there is no < operator to compare a Boolean value with 3).

In addition to the comparison operators, the special `BETWEEN` construct is available.

```
a BETWEEN x AND y
```

is equivalent to

```
a >= x AND a <= y
```

Similarly,

```
a NOT BETWEEN x AND y
```

is equivalent to

```
a < x OR a > y
```

There is no difference between the two respective forms apart from the CPU cycles required to rewrite the first one into the second one internally. `BETWEEN SYMMETRIC` is the same as `BETWEEN` except there is no requirement that the argument to the left of `AND` be less than or equal to the argument on the right; the proper range is automatically determined.

To check whether a value is or is not null, use the constructs

```
expression IS NULL
expression IS NOT NULL
```

or the equivalent, but nonstandard, constructs

```
expression ISNULL
```

```
expression NOTNULL
```

Do *not* write `expression = NULL` because `NULL` is not “equal to” `NULL`. (The null value represents an unknown value, and it is not known whether two unknown values are equal.) This behavior conforms to the SQL standard.

**Tip:** Some applications might expect that `expression = NULL` returns true if `expression` evaluates to the null value. It is highly recommended that these applications be modified to comply with the SQL standard. However, if that cannot be done the `transform_null_equals` configuration variable is available. If it is enabled, PostgreSQL will convert `x = NULL` clauses to `x IS NULL`. This was the default behavior in PostgreSQL releases 6.5 through 7.1.

**Note:** If the `expression` is row-valued, then `IS NULL` is true when the row expression itself is null or when all the row’s fields are null, while `IS NOT NULL` is true when the row expression itself is non-null and all the row’s fields are non-null. This definition conforms to the SQL standard, and is a change from the inconsistent behavior exhibited by PostgreSQL versions prior to 8.2.

The ordinary comparison operators yield null (signifying “unknown”) when either input is null. Another way to do comparisons is with the `IS [ NOT ] DISTINCT FROM` construct:

```
expression IS DISTINCT FROM expression
expression IS NOT DISTINCT FROM expression
```

For non-null inputs, `IS DISTINCT FROM` is the same as the `<>` operator. However, when both inputs are null it will return false, and when just one input is null it will return true. Similarly, `IS NOT DISTINCT FROM` is identical to `=` for non-null inputs, but it returns true when both inputs are null, and false when only one input is null. Thus, these constructs effectively act as though null were a normal data value, rather than “unknown”.

Boolean values can also be tested using the constructs

```
expression IS TRUE
expression IS NOT TRUE
expression IS FALSE
expression IS NOT FALSE
expression IS UNKNOWN
expression IS NOT UNKNOWN
```

These will always return true or false, never a null value, even when the operand is null. A null input is treated as the logical value “unknown”. Notice that `IS UNKNOWN` and `IS NOT UNKNOWN` are effectively the same as `IS NULL` and `IS NOT NULL`, respectively, except that the input expression must be of Boolean type.

## 9.3. Mathematical Functions and Operators

Mathematical operators are provided for many PostgreSQL types. For types without common mathematical conventions for all possible permutations (e.g., date/time types) we describe the actual behavior in subsequent sections.

Table 9-2 shows the available mathematical operators.

**Table 9-2. Mathematical Operators**

Operator	Description	Example	Result
+	addition	2 + 3	5
-	subtraction	2 - 3	-1
*	multiplication	2 * 3	6
/	division (integer division truncates results)	4 / 2	2
%	modulo (remainder)	5 % 4	1
^	exponentiation	2.0 ^ 3.0	8
/	square root	/ 25.0	5
/	cube root	/ 27.0	3
!	factorial	5 !	120
!!	factorial (prefix operator)	!! 5	120
@	absolute value	@ -5.0	5
&	bitwise AND	91 & 15	11
	bitwise OR	32   3	35
#	bitwise XOR	17 # 5	20
~	bitwise NOT	~1	-2
<<	bitwise shift left	1 << 4	16
>>	bitwise shift right	8 >> 2	2

The bitwise operators work only on integral data types, whereas the others are available for all numeric data types. The bitwise operators are also available for the bit string types `bit` and `bit varying`, as shown in Table 9-10.

Table 9-3 shows the available mathematical functions. In the table, `dp` indicates `double precision`. Many of these functions are provided in multiple forms with different argument types. Except where noted, any given form of a function returns the same data type as its argument. The functions working with `double precision` data are mostly implemented on top of the host system's C library; accuracy and behavior in boundary cases can therefore vary depending on the host system.

**Table 9-3. Mathematical Functions**

Function	Return Type	Description	Example	Result
----------	-------------	-------------	---------	--------

Function	Return Type	Description	Example	Result
<code>abs(x)</code>	(same as <i>x</i> )	absolute value	<code>abs(-17.4)</code>	17.4
<code>cbrt(dp)</code>	dp	cube root	<code>cbrt(27.0)</code>	3
<code>ceil(dp or numeric)</code>	(same as input)	smallest integer not less than argument	<code>ceil(-42.8)</code>	-42
<code>ceiling(dp or numeric)</code>	(same as input)	smallest integer not less than argument (alias for <code>ceil</code> )	<code>ceiling(-95.3)</code>	-95
<code>degrees(dp)</code>	dp	radians to degrees	<code>degrees(0.5)</code>	28.6478897565412
<code>exp(dp or numeric)</code>	(same as input)	exponential	<code>exp(1.0)</code>	2.71828182845905
<code>floor(dp or numeric)</code>	(same as input)	largest integer not greater than argument	<code>floor(-42.8)</code>	-43
<code>ln(dp or numeric)</code>	(same as input)	natural logarithm	<code>ln(2.0)</code>	0.693147180559945
<code>log(dp or numeric)</code>	(same as input)	base 10 logarithm	<code>log(100.0)</code>	2
<code>log(b numeric, x numeric)</code>	numeric	logarithm to base <i>b</i>	<code>log(2.0, 64.0)</code>	6.0000000000
<code>mod(y, x)</code>	(same as argument types)	remainder of <i>y/x</i>	<code>mod(9, 4)</code>	1
<code>pi()</code>	dp	“ $\pi$ ” constant	<code>pi()</code>	3.14159265358979
<code>power(a dp, b dp)</code>	dp	<i>a</i> raised to the power of <i>b</i>	<code>power(9.0, 3.0)</code>	729
<code>power(a numeric, b numeric)</code>	numeric	<i>a</i> raised to the power of <i>b</i>	<code>power(9.0, 3.0)</code>	729
<code>radians(dp)</code>	dp	degrees to radians	<code>radians(45.0)</code>	0.785398163397448
<code>random()</code>	dp	random value between 0.0 and 1.0	<code>random()</code>	
<code>round(dp or numeric)</code>	(same as input)	round to nearest integer	<code>round(42.4)</code>	42
<code>round(v numeric, s int)</code>	numeric	round to <i>s</i> decimal places	<code>round(42.4382, 2)</code>	42.44

Function	Return Type	Description	Example	Result
<code>setseed(dp)</code>	<code>void</code>	set seed for subsequent <code>random()</code> calls (value between 0 and 1.0)	<code>setseed(0.54823)</code>	
<code>sign(dp or numeric)</code>	(same as input)	sign of the argument (-1, 0, +1)	<code>sign(-8.4)</code>	-1
<code>sqrt(dp or numeric)</code>	(same as input)	square root	<code>sqrt(2.0)</code>	1.4142135623731
<code>trunc(dp or numeric)</code>	(same as input)	truncate toward zero	<code>trunc(42.8)</code>	42
<code>trunc(v numeric, s int)</code>	<code>numeric</code>	truncate to <code>s</code> decimal places	<code>trunc(42.4382, 2)</code>	42.43
<code>width_bucket(op numeric, b1 numeric, b2 numeric, count int)</code>	<code>int</code>	return the bucket to which operand would be assigned in an equidepth histogram with <code>count</code> buckets, in the range <code>b1</code> to <code>b2</code>	<code>width_bucket(5.35, 0.024, 10.06, 5)</code>	
<code>width_bucket(op dp, b1 dp, b2 dp, count int)</code>	<code>int</code>	return the bucket to which operand would be assigned in an equidepth histogram with <code>count</code> buckets, in the range <code>b1</code> to <code>b2</code>	<code>width_bucket(5.35, 0.024, 10.06, 5)</code>	

Finally, Table 9-4 shows the available trigonometric functions. All trigonometric functions take arguments and return values of type `double precision`.

**Table 9-4. Trigonometric Functions**

Function	Description
<code>acos(x)</code>	inverse cosine
<code>asin(x)</code>	inverse sine
<code>atan(x)</code>	inverse tangent
<code>atan2(y, x)</code>	inverse tangent of $y/x$
<code>cos(x)</code>	cosine
<code>cot(x)</code>	cotangent
<code>sin(x)</code>	sine
<code>tan(x)</code>	tangent

## 9.4. String Functions and Operators

This section describes functions and operators for examining and manipulating string values. Strings in this context include values of the types `character`, `character varying`, and `text`. Unless otherwise noted, all of the functions listed below work on all of these types, but be wary of potential effects of automatic space-padding when using the `character` type. Some functions also exist natively for the bit-string types.

SQL defines some string functions with a special syntax wherein certain key words rather than commas are used to separate the arguments. Details are in Table 9-5. These functions are also implemented using the regular syntax for function invocation. (See Table 9-6.)

**Note:** Before PostgreSQL 8.3, these functions would silently accept values of several non-string data types as well, due to the presence of implicit coercions from those data types to `text`. Those coercions have been removed because they frequently caused surprising behaviors. However, the string concatenation operator (`||`) still accepts non-string input, so long as at least one input is of a string type, as shown in Table 9-5. For other cases, insert an explicit coercion to `text` if you need to duplicate the previous behavior.

**Table 9-5. SQL String Functions and Operators**

Function	Return Type	Description	Example	Result
<code>string    string</code>	<code>text</code>	String concatenation	<code>'Post'    'greSQL'</code>	PostgreSQL
<code>string    non-string</code> or <code>non-string    string</code>	<code>text</code>	String concatenation with one non-string input	<code>'Value: '    42</code>	Value: 42
<code>bit_length(string)</code>	<code>int</code>	Number of bits in string	<code>bit_length('jose')</code>	32
<code>char_length(string)</code> or <code>character_length(string)</code>	<code>int</code>	Number of characters in string	<code>char_length('jose')</code>	4
<code>lower(string)</code>	<code>text</code>	Convert string to lower case	<code>lower('TOM')</code>	tom
<code>octet_length(string)</code>	<code>int</code>	Number of bytes in string	<code>octet_length('jose')</code>	4
<code>overlay(string placing string from int [for int])</code>	<code>text</code>	Replace substring	<code>overlay('Txxxxas' placing 'hom' from 2 for 4)</code>	Thomas
<code>position(substring in string)</code>	<code>int</code>	Location of specified substring	<code>position('om' in 'Thomas')</code>	3

Function	Return Type	Description	Example	Result
<code>substring(string [from int] [for int])</code>	text	Extract substring	<code>substring('Thomas' from 2 for 3)</code>	tom
<code>substring(string from pattern)</code>	text	Extract substring matching POSIX regular expression. See Section 9.7 for more information on pattern matching.	<code>substring('Thomas' from '...\$')</code>	as
<code>substring(string from pattern for escape)</code>	text	Extract substring matching SQL regular expression. See Section 9.7 for more information on pattern matching.	<code>substring('Thomas' from '%#"o_a#"_' for '#')</code>	as
<code>trim([leading   trailing   both] [characters] from string)</code>	text	Remove the longest string containing only the characters (a space by default) from the start/end/both ends of the string	<code>trim(both 'x' from 'xTomxx')</code>	Tom
<code>upper(string)</code>	text	Convert string to uppercase	<code>upper('tom')</code>	TOM

Additional string manipulation functions are available and are listed in Table 9-6. Some of them are used internally to implement the SQL-standard string functions listed in Table 9-5.

**Table 9-6. Other String Functions**

Function	Return Type	Description	Example	Result
<code>ascii(string)</code>	int	ASCII code of the first character of the argument. For UTF8 returns the Unicode code point of the character. For other multibyte encodings, the argument must be a strictly ASCII character.	<code>ascii('x')</code>	120

Function	Return Type	Description	Example	Result
<code>btrim(string text [, characters text])</code>	text	Remove the longest string consisting only of characters in characters (a space by default) from the start and end of string	<code>btrim('xytrimxytrim 'xy')</code>	
<code>chr(int)</code>	text	Character with the given code. For UTF8 the argument is treated as a Unicode code point. For other multibyte encodings the argument must designate a strictly ASCII character. The NULL (0) character is not allowed because text data types cannot store such bytes.	<code>chr(65)</code>	A
<code>convert(string bytea, src_encoding name, dest_encoding name)</code>	bytea	Convert string to dest_encoding. The original encoding is specified by src_encoding. The string must be valid in this encoding. Conversions can be defined by CREATE CONVERSION. Also there are some predefined conversions. See Table 9-7 for available conversions.	<code>convert('text_in_utf8', 'UTF8', 'LATIN1')</code>	text_in_utf8 represented in ISO 8859-1 encoding

Function	Return Type	Description	Example	Result
<code>convert_from(string bytea, src_encoding name)</code>	text	Convert string to the database encoding. The original encoding is specified by <code>src_encoding</code> . The string must be valid in this encoding.	<code>convert_from('text', 'UTF8')</code>	text represented in the current database encoding
<code>convert_to(string text, dest_encoding name)</code>	bytea	Convert string to <code>dest_encoding</code> .	<code>convert_to('some text', 'UTF8')</code>	some text represented in the UTF8 encoding
<code>decode(string text, type text)</code>	bytea	Decode binary data from string previously encoded with <code>encode</code> . Parameter type is same as in <code>encode</code> .	<code>decode('MTIzAAE=', 'base64')</code>	123\000\001
<code>encode(data bytea, type text)</code>	text	Encode binary data to different representation. Supported types are: <code>base64</code> , <code>hex</code> , <code>escape</code> . <code>escape</code> merely outputs null bytes as <code>\000</code> and doubles backslashes.	<code>encode(E'123\000\001', 'base64')</code>	MTIzAAE=
<code>initcap(string)</code>	text	Convert the first letter of each word to uppercase and the rest to lowercase. Words are sequences of alphanumeric characters separated by non-alphanumeric characters.	<code>initcap('hi THOMAS')</code>	Hi Thomas
<code>length(string)</code>	int	Number of characters in string	<code>length('jose')</code>	4

Function	Return Type	Description	Example	Result
<code>length(stringbytea, int encoding name )</code>	int	Number of characters in string in the given encoding. The string must be valid in this encoding.	<code>length('jose', 'UTF8')</code>	4
<code>lpad(string text, length int [, fill text])</code>	text	Fill up the string to length length by prepending the characters fill (a space by default). If the string is already longer than length then it is truncated (on the right).	<code>lpad('hi', 5, 'xy')</code>	xyxhi
<code>ltrim(string text [, characters text])</code>	text	Remove the longest string containing only characters from the start of string (a space by default).	<code>ltrim('zzzytrim', 'xyz')</code>	trim
<code>md5(string)</code>	text	Calculates the MD5 hash of string, returning the result in hexadecimal	<code>md5('abc')</code>	900150983cd24fb0d6963f7d28e17f72
<code>pg_client_encoding()</code>	name	Current client encoding name	<code>pg_client_encoding()</code>	SQL_ASCII

Function	Return Type	Description	Example	Result
<code>quote_ident(string text)</code>	text	Return the given string suitably quoted to be used as an identifier in an SQL statement string. Quotes are added only if necessary (i.e., if the string contains non-identifier characters or would be case-folded). Embedded quotes are properly doubled.	<code>quote_ident('Foo bar')</code>	"Foo bar"
<code>quote_literal(string text)</code>	text	Return the given string suitably quoted to be used as a string literal in an SQL statement string. Embedded single-quotes and backslashes are properly doubled.	<code>quote_literal('O\'Reilly')</code>	'O\'Reilly'
<code>quote_literal(value anyelement)</code>	text	Coerce the given value to text and then quote it as a literal. Embedded single-quotes and backslashes are properly doubled.	<code>quote_literal(42.5)</code>	42.5
<code>regexp_matches(string text, pattern text [, flags text])</code>	set of text[]	Return all captured substrings resulting from matching a POSIX regular expression against the string. See Section 9.7.3 for more information.	<code>regexp_matches('foobarbequebaz', '(bar) (beque)')</code>	{bar,beque}

Function	Return Type	Description	Example	Result
<code>regexp_replace(string text, pattern text, replacement text [, flags text])</code>	text	Replace substring(s) matching a POSIX regular expression. See Section 9.7.3 for more information.	<code>regexp_replace('Thomas', '.[mN]a.', 'M')</code>	ThMmas
<code>regexp_split_to_array(string text, pattern text [, flags text ])</code>	text[]	Split string using a POSIX regular expression as the delimiter. See Section 9.7.3 for more information.	<code>regexp_split_to_array('hello world', E'\\s+')</code>	{hello, world}
<code>regexp_split_to_table(string text, pattern text [, flags text])</code>	table	Split string using a POSIX regular expression as the delimiter. See Section 9.7.3 for more information.	<code>regexp_split_to_table('hello world', E'\\s+')</code>	table with 1(2 rows)
<code>repeat(string text, number int)</code>	text	Repeat string the specified number of times	<code>repeat('Pg', 4)</code>	PgPgPgPg
<code>replace(string text, from text, to text)</code>	text	Replace all occurrences in string of substring from with substring to	<code>replace('abcdefabcdef', 'cd', 'XX')</code>	abXXefabXXef
<code>rpadd(string text, length int [, fill text])</code>	text	Fill up the string to length length by appending the characters fill (a space by default). If the string is already longer than length then it is truncated.	<code>rpadd('hi', 5, 'xy')</code>	hixyx

Function	Return Type	Description	Example	Result
<code>rtrim(string text [, characters text])</code>	text	Remove the longest string containing only characters from characters (a space by default) from the end of string	<code>rtrim('trimxxxx', 'x')</code>	<code>trim</code>
<code>split_part(string text, delimiter text, field int)</code>	text	Split string on delimiter and return the given field (counting from one)	<code>split_part('abcdef~@~ghi', '~@~', 2)</code>	<code>def</code>
<code>strpos(string, substring)</code>	int	Location of specified substring (same as <code>position(substring in string)</code> , but note the reversed argument order)	<code>strpos('high', 'ig')</code>	<code>2</code>
<code>substr(string, from [, count])</code>	text	Extract substring (same as <code>substring(string from from for count)</code> )	<code>substr('alphabet', 3, 2)</code>	<code>ph</code>
<code>to_ascii(string text [, encoding text])</code>	text	Convert string to ASCII from another encoding (only supports conversion from LATIN1, LATIN2, LATIN9, and WIN1250 encodings)	<code>to_ascii('Karel')</code>	<code>Karel</code>
<code>to_hex(number int or bigint)</code>	text	Convert number to its equivalent hexadecimal representation	<code>to_hex(2147483647)</code>	<code>ffffffffff</code>

Function	Return Type	Description	Example	Result
<code>translate(string text, from text, to text)</code>	text	Any character in string that matches a character in the from set is replaced by the corresponding character in the to set	<code>translate('123456789', '14', 'ax')</code>	ax23x5

shift_jis_2004_to_euc_jis_2004	SHIFT_JIS_2004	EUC_JIS_2004
<b>Notes:</b> a. The conversion names follow a standard naming scheme: The official name of the source encoding with all non-alphanumeric characters replaced by underscores followed by <code>_to_</code> followed by the equally processed destination encoding name. Therefore the names might deviate from the customary encoding names.		

## 9.5. Binary String Functions and Operators

This section describes functions and operators for examining and manipulating values of type `bytea`.

SQL defines some string functions with a special syntax where certain key words rather than commas are used to separate the arguments. Details are in Table 9-8. Some functions are also implemented using the regular syntax for function invocation. (See Table 9-9.)

**Table 9-8. SQL Binary String Functions and Operators**

Function	Return Type	Description	Example	Result
<code>string    string</code>	<code>bytea</code>	String concatenation	<code>E'\\Post'::bytea    E'\\047gres\\000'::bytea</code>	<code>Post'gres\\00047gres\\000'::bytea</code>
<code>get_bit(string, int offset)</code>	<code>int</code>	Extract bit from string	<code>get_bit(E'Th\\000omas'::bytea, 45)</code>	<code>0</code>
<code>get_byte(string, int offset)</code>	<code>int</code>	Extract byte from string	<code>get_byte(E'Th\\000omas'::bytea, 4)</code>	<code>100</code>
<code>octet_length(string)</code>	<code>int</code>	Number of bytes in binary string	<code>octet_length(E'j5\\000se'::bytea)</code>	<code>5</code>
<code>position(substring in string)</code>	<code>int</code>	Location of specified substring	<code>position(E'\\000m'::bytea in E'Th\\000omas'::bytea)</code>	<code>3</code>
<code>set_bit(string, offset, newvalue)</code>	<code>bytea</code>	Set bit in string	<code>set_bit(E'Th\\000omas'::bytea, 45, 0)</code>	<code>Th\\000omas'::bytea</code>
<code>set_byte(string, offset, newvalue)</code>	<code>bytea</code>	Set byte in string	<code>set_byte(E'Th\\000omas'::bytea, 4, 64)</code>	<code>Th\\000omas'::bytea</code>
<code>substring(string [from int] [for int])</code>	<code>bytea</code>	Extract substring	<code>substring(E'Th\\000omas'::bytea from 2 for 3)</code>	<code>h\\000om'::bytea</code>
<code>trim([both] bytes from string)</code>	<code>bytea</code>	Remove the longest string containing only the bytes in bytes from the start and end of string	<code>trim(E'\\000'::bytea from E'\\000Tom\\000'::bytea)</code>	<code>Tom'::bytea</code>

Additional binary string manipulation functions are available and are listed in Table 9-9. Some of them are used internally to implement the SQL-standard string functions listed in Table 9-8.

**Table 9-9. Other Binary String Functions**

Function	Return Type	Description	Example	Result
----------	-------------	-------------	---------	--------

Function	Return Type	Description	Example	Result
<code>btrim(string bytea, bytes bytea)</code>	bytea	Remove the longest string consisting only of bytes in <code>bytes</code> from the start and end of <code>string</code>	<code>btrim(E'\\000trim\\000'::bytea, E'\\000'::bytea)</code>	
<code>decode(string text, type text)</code>	bytea	Decode binary string from string previously encoded with <code>encode</code> . Parameter type is same as in <code>encode</code> .	<code>decode(E'123\\000245670456 'escape')</code>	
<code>encode(string bytea, type text)</code>	text	Encode binary string to ASCII-only representation. Supported types are: <code>base64</code> , <code>hex</code> , <code>escape</code> .	<code>encode(E'123\\000245670456 'escape')</code>	
<code>length(string)</code>	int	Length of binary string	<code>length(E'jo\\0005e'::bytea)</code>	
<code>md5(string)</code>	text	Calculates the MD5 hash of string, returning the result in hexadecimal	<code>md5(E'Th\\000omash\\0009aaf18 b4958c334c82d8b1</code>	

## 9.6. Bit String Functions and Operators

This section describes functions and operators for examining and manipulating bit strings, that is values of the types `bit` and `bit varying`. Aside from the usual comparison operators, the operators shown in Table 9-10 can be used. Bit string operands of `&`, `|`, and `#` must be of equal length. When bit shifting, the original length of the string is preserved, as shown in the examples.

**Table 9-10. Bit String Operators**

Operator	Description	Example	Result
<code>  </code>	concatenation	<code>B'10001'    B'011'</code>	10001011
<code>&amp;</code>	bitwise AND	<code>B'10001' &amp; B'01101'</code>	00001

Operator	Description	Example	Result
	bitwise OR	B'10001'   B'01101'	11101
#	bitwise XOR	B'10001' # B'01101'	11100
~	bitwise NOT	~ B'10001'	01110
<<	bitwise shift left	B'10001' << 3	01000
>>	bitwise shift right	B'10001' >> 2	00100

The following SQL-standard functions work on bit strings as well as character strings: `length`, `bit_length`, `octet_length`, `position`, `substring`.

In addition, it is possible to cast integral values to and from type `bit`. Some examples:

```
44::bit(10)           0000101100
44::bit(3)            100
cast(-44 as bit(12))  111111010100
'1110'::bit(4)::integer 14
```

Note that casting to just “bit” means casting to `bit(1)`, and so it will deliver only the least significant bit of the integer.

**Note:** Prior to PostgreSQL 8.0, casting an integer to `bit(n)` would copy the leftmost `n` bits of the integer, whereas now it copies the rightmost `n` bits. Also, casting an integer to a bit string width wider than the integer itself will sign-extend on the left.

## 9.7. Pattern Matching

There are three separate approaches to pattern matching provided by PostgreSQL: the traditional SQL `LIKE` operator, the more recent `SIMILAR TO` operator (added in SQL:1999), and POSIX-style regular expressions. Aside from the basic “does this string match this pattern?” operators, functions are available to extract or replace matching substrings and to split a string at the matches.

**Tip:** If you have pattern matching needs that go beyond this, consider writing a user-defined function in Perl or Tcl.

### 9.7.1. LIKE

```
string LIKE pattern [ESCAPE escape-character]
string NOT LIKE pattern [ESCAPE escape-character]
```

Every *pattern* defines a set of strings. The `LIKE` expression returns true if the *string* is contained in the set of strings represented by *pattern*. (As expected, the `NOT LIKE` expression returns false if `LIKE` returns true, and vice versa. An equivalent expression is `NOT (string LIKE pattern)`.)

If *pattern* does not contain percent signs or underscore, then the pattern only represents the string itself; in that case `LIKE` acts like the equals operator. An underscore (`_`) in *pattern* stands for (matches) any single character; a percent sign (`%`) matches any string of zero or more characters.

Some examples:

```
'abc' LIKE 'abc'      true
'abc' LIKE 'a%'       true
'abc' LIKE '_b_'      true
'abc' LIKE 'c'        false
```

`LIKE` pattern matches always cover the entire string. To match a sequence anywhere within a string, the pattern must therefore start and end with a percent sign.

To match a literal underscore or percent sign without matching other characters, the respective character in *pattern* must be preceded by the escape character. The default escape character is the backslash but a different one can be selected by using the `ESCAPE` clause. To match the escape character itself, write two escape characters.

Note that the backslash already has a special meaning in string literals, so to write a pattern constant that contains a backslash you must write two backslashes in an SQL statement (assuming escape string syntax is used, see Section 4.1.2.1). Thus, writing a pattern that actually matches a literal backslash means writing four backslashes in the statement. You can avoid this by selecting a different escape character with `ESCAPE`; then a backslash is not special to `LIKE` anymore. (But it is still special to the string literal parser, so you still need two of them.)

It's also possible to select no escape character by writing `ESCAPE ''`. This effectively disables the escape mechanism, which makes it impossible to turn off the special meaning of underscore and percent signs in the pattern.

The key word `ILIKE` can be used instead of `LIKE` to make the match case-insensitive according to the active locale. This is not in the SQL standard but is a PostgreSQL extension.

The operator `~~` is equivalent to `LIKE`, and `~~*` corresponds to `ILIKE`. There are also `!~~` and `!~~*` operators that represent `NOT LIKE` and `NOT ILIKE`, respectively. All of these operators are PostgreSQL-specific.

## 9.7.2. SIMILAR TO Regular Expressions

```
string SIMILAR TO pattern [ESCAPE escape-character]
string NOT SIMILAR TO pattern [ESCAPE escape-character]
```

The `SIMILAR TO` operator returns true or false depending on whether its pattern matches the given string. It is much like `LIKE`, except that it interprets the pattern using the SQL standard's definition of a regular expression. SQL regular expressions are a curious cross between `LIKE` notation and common regular expression notation.

Like `LIKE`, the `SIMILAR TO` operator succeeds only if its pattern matches the entire string; this is unlike common regular expression practice, wherein the pattern can match any part of the string. Also like `LIKE`, `SIMILAR TO` uses `_` and `%` as wildcard characters denoting any single character and any string, respectively (these are comparable to `.` and `.*` in POSIX regular expressions).

In addition to these facilities borrowed from `LIKE`, `SIMILAR TO` supports these pattern-matching metacharacters borrowed from POSIX regular expressions:

- `|` denotes alternation (either of two alternatives).
- `*` denotes repetition of the previous item zero or more times.
- `+` denotes repetition of the previous item one or more times.
- Parentheses `()` can be used to group items into a single logical item.
- A bracket expression `[...]` specifies a character class, just as in POSIX regular expressions.

Notice that bounded repetition (`?` and `{...}`) are not provided, though they exist in POSIX. Also, the dot (`.`) is not a metacharacter.

As with `LIKE`, a backslash disables the special meaning of any of these metacharacters; or a different escape character can be specified with `ESCAPE`.

Some examples:

```
'abc' SIMILAR TO 'abc'      true
'abc' SIMILAR TO 'a'        false
'abc' SIMILAR TO '%(b|d)%'  true
'abc' SIMILAR TO '(b|c)%'   false
```

The `substring` function with three parameters, `substring(string from pattern for escape-character)`, provides extraction of a substring that matches an SQL regular expression pattern. As with `SIMILAR TO`, the specified pattern must match to the entire data string, else the function fails and returns null. To indicate the part of the pattern that should be returned on success, the pattern must contain two occurrences of the escape character followed by a double quote (`"`). The text matching the portion of the pattern between these markers is returned.

Some examples:

```
substring('foobar' from '%"_b#"' for '#')    oob
substring('foobar' from '%"_b#"' for '#')    NULL
```

### 9.7.3. POSIX Regular Expressions

Table 9-11 lists the available operators for pattern matching using POSIX regular expressions.

Operator	Description	Example
----------	-------------	---------

Table 9-11. Regular Expression Match Operators

Operator	Description	Example
<code>~</code>	Matches regular expression, case sensitive	<code>'thomas' ~ '*.thomas.*'</code>
<code>~*</code>	Matches regular expression, case insensitive	<code>'thomas' ~* '*.Thomas.*'</code>
<code>!~</code>	Does not match regular expression, case sensitive	<code>'thomas' !~ '*.Thomas.*'</code>
<code>!~*</code>	Does not match regular expression, case insensitive	<code>'thomas' !~* '*.vadim.*'</code>

POSIX regular expressions provide a more powerful means for pattern matching than the `LIKE` and `SIMILAR TO` operators. Many Unix tools such as `egrep`, `sed`, or `awk` use a pattern matching language that is similar to the one described here.

A regular expression is a character sequence that is an abbreviated definition of a set of strings (a *regular set*). A string is said to match a regular expression if it is a member of the regular set described by the regular expression. As with `LIKE`, pattern characters match string characters exactly unless they are special characters in the regular expression language — but regular expressions use different special characters than `LIKE` does. Unlike `LIKE` patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.

Some examples:

```
'abc' ~ 'abc'      true
'abc' ~ '^a'       true
'abc' ~ '(b|d)'    true
'abc' ~ '^(b|c)'   false
```

The POSIX pattern language is described in much greater detail below.

The `substring` function with two parameters, `substring(string from pattern)`, provides extraction of a substring that matches a POSIX regular expression pattern. It returns null if there is no match, otherwise the portion of the text that matched the pattern. But if the pattern contains any parentheses, the portion of the text that matched the first parenthesized subexpression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception. If you need parentheses in the pattern before the subexpression you want to extract, see the non-capturing parentheses described below.

Some examples:

```
substring('foobar' from 'o.b')      oob
substring('foobar' from 'o(.)b')    o
```

The `regexp_replace` function provides substitution of new text for substrings that match POSIX regular expression patterns. It has the syntax `regexp_replace(source, pattern, replacement [, flags`

]). The *source* string is returned unchanged if there is no match to the *pattern*. If there is a match, the *source* string is returned with the *replacement* string substituted for the matching substring. The *replacement* string can contain `\n`, where *n* is 1 through 9, to indicate that the source substring matching the *n*'th parenthesized subexpression of the pattern should be inserted, and it can contain `&` to indicate that the substring matching the entire pattern should be inserted. Write `\\` if you need to put a literal backslash in the replacement text. (As always, remember to double backslashes written in literal constant strings, assuming escape string syntax is used.) The *flags* parameter is an optional text string containing zero or more single-letter flags that change the function's behavior. Flag `i` specifies case-insensitive matching, while flag `g` specifies replacement of each matching substring rather than only the first one. Other supported flags are described in Table 9-19.

Some examples:

```
regexp_replace('foobarbaz', 'b..', 'X')
      fooXbaz
regexp_replace('foobarbaz', 'b..', 'X', 'g')
      fooXX
regexp_replace('foobarbaz', 'b(..)', E'X\\1Y', 'g')
      fooXarYXazY
```

The `regexp_matches` function returns all of the captured substrings resulting from matching a POSIX regular expression pattern. It has the syntax `regexp_matches(string, pattern [, flags])`. If there is no match to the *pattern*, the function returns no rows. If there is a match, the function returns a text array whose *n*'th element is the substring matching the *n*'th parenthesized subexpression of the pattern (not counting “non-capturing” parentheses; see below for details). If the pattern does not contain any parenthesized subexpressions, then the result is a single-element text array containing the substring matching the whole pattern. The *flags* parameter is an optional text string containing zero or more single-letter flags that change the function's behavior. Flag `g` causes the function to find each match in the string, not only the first one, and return a row for each such match. Other supported flags are described in Table 9-19.

Some examples:

```
SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
 regexp_matches
-----
 {bar,beque}
(1 row)

SELECT regexp_matches('foobarbequebazilbarfbonk', '(b(^b)+)(b[^b]+)', 'g');
 regexp_matches
-----
 {bar,beque}
 {bazil,barf}
(2 rows)

SELECT regexp_matches('foobarbequebaz', 'barbeque');
 regexp_matches
-----
 {barbeque}
(1 row)
```

The `regexp_split_to_table` function splits a string using a POSIX regular expression pattern as a delimiter. It has the syntax `regexp_split_to_table(string, pattern [, flags ])`. If there is no match to the *pattern*, the function returns the *string*. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string. The *flags* parameter is an optional text string containing zero or more single-letter flags that change the function's behavior. `regexp_split_to_table` supports the flags described in Table 9-19.

The `regexp_split_to_array` function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text. It has the syntax `regexp_split_to_array(string, pattern [, flags ])`. The parameters are the same as for `regexp_split_to_table`.

Some examples:

```
SELECT foo FROM regexp_split_to_table('the quick brown fox jumped over the lazy dog', E'\\s')
foo
-----
the
quick
brown
fox
jumped
over
the
lazy
dog
(9 rows)

SELECT regexp_split_to_array('the quick brown fox jumped over the lazy dog', E'\\s+');
      regexp_split_to_array
-----
{the,quick,brown,fox,jumped,over,the,lazy,dog}
(1 row)

SELECT foo FROM regexp_split_to_table('the quick brown fox', E'\\s*') AS foo;
foo
-----
t
h
e
q
u
i
c
k
b
r
o
w
n
f
```

```

o
x
(16 rows)

```

As the last example demonstrates, the regexp split functions ignore zero-length matches that occur at the start or end of the string or immediately after a previous match. This is contrary to the strict definition of regexp matching that is implemented by `regexp_matches`, but is usually the most convenient behavior in practice. Other software systems such as Perl use similar definitions.

### 9.7.3.1. Regular Expression Details

PostgreSQL's regular expressions are implemented using a package written by Henry Spencer. Much of the description of regular expressions below is copied verbatim from his manual entry.

Regular expressions (REs), as defined in POSIX 1003.2, come in two forms: *extended* REs or EREs (roughly those of `egrep`), and *basic* REs or BREs (roughly those of `ed`). PostgreSQL supports both forms, and also implements some extensions that are not in the POSIX standard, but have become widely used anyway due to their availability in programming languages such as Perl and Tcl. REs using these non-POSIX extensions are called *advanced* REs or AREs in this documentation. AREs are almost an exact superset of EREs, but BREs have several notational incompatibilities (as well as being much more limited). We first describe the ARE and ERE forms, noting features that apply only to AREs, and then describe how BREs differ.

**Note:** The form of regular expressions accepted by PostgreSQL can be chosen by setting the `regex_flavor` run-time parameter. The usual setting is `advanced`, but one might choose `extended` for maximum backwards compatibility with pre-7.4 releases of PostgreSQL.

A regular expression is defined as one or more *branches*, separated by `|`. It matches anything that matches one of the branches.

A branch is zero or more *quantified atoms* or *constraints*, concatenated. It matches a match for the first, followed by a match for the second, etc; an empty branch matches the empty string.

A quantified atom is an *atom* possibly followed by a single *quantifier*. Without a quantifier, it matches a match for the atom. With a quantifier, it can match some number of matches of the atom. An *atom* can be any of the possibilities shown in Table 9-12. The possible quantifiers and their meanings are shown in Table 9-13.

A *constraint* matches an empty string, but matches only when specific conditions are met. A constraint can be used where an atom could be used, except it cannot be followed by a quantifier. The simple constraints are shown in Table 9-14; some more constraints are described later.

**Table 9-12. Regular Expression Atoms**

Atom	Description
<code>(re)</code>	(where <i>re</i> is any regular expression) matches a match for <i>re</i> , with the match noted for possible reporting

Atom	Description
<code>(?:<i>re</i>)</code>	as above, but the match is not noted for reporting (a “non-capturing” set of parentheses) (AREs only)
<code>.</code>	matches any single character
<code>[<i>chars</i>]</code>	a <i>bracket expression</i> , matching any one of the <i>chars</i> (see Section 9.7.3.2 for more detail)
<code>\k</code>	(where <i>k</i> is a non-alphanumeric character) matches that character taken as an ordinary character, e.g. <code>\\</code> matches a backslash character
<code>\c</code>	where <i>c</i> is alphanumeric (possibly followed by other characters) is an <i>escape</i> , see Section 9.7.3.3 (AREs only; in EREs and BREs, this matches <i>c</i> )
<code>{</code>	when followed by a character other than a digit, matches the left-brace character <code>{</code> ; when followed by a digit, it is the beginning of a <i>bound</i> (see below)
<code>x</code>	where <i>x</i> is a single character with no other significance, matches that character

An RE cannot end with `\`.

**Note:** Remember that the backslash (`\`) already has a special meaning in PostgreSQL string literals. To write a pattern constant that contains a backslash, you must write two backslashes in the statement, assuming escape string syntax is used (see Section 4.1.2.1).

**Table 9-13. Regular Expression Quantifiers**

Quantifier	Matches
<code>*</code>	a sequence of 0 or more matches of the atom
<code>+</code>	a sequence of 1 or more matches of the atom
<code>?</code>	a sequence of 0 or 1 matches of the atom
<code>{<i>m</i>}</code>	a sequence of exactly <i>m</i> matches of the atom
<code>{<i>m</i>, }</code>	a sequence of <i>m</i> or more matches of the atom
<code>{<i>m</i>, <i>n</i>}</code>	a sequence of <i>m</i> through <i>n</i> (inclusive) matches of the atom; <i>m</i> cannot exceed <i>n</i>
<code>*?</code>	non-greedy version of <code>*</code>
<code>+?</code>	non-greedy version of <code>+</code>
<code>??</code>	non-greedy version of <code>?</code>
<code>{<i>m</i>}?</code>	non-greedy version of <code>{<i>m</i>}</code>
<code>{<i>m</i>, }?</code>	non-greedy version of <code>{<i>m</i>, }</code>
<code>{<i>m</i>, <i>n</i>}?</code>	non-greedy version of <code>{<i>m</i>, <i>n</i>}</code>

The forms using `{ . . . }` are known as *bounds*. The numbers *m* and *n* within a bound are unsigned decimal integers with permissible values from 0 to 255 inclusive.

*Non-greedy* quantifiers (available in AREs only) match the same possibilities as their corresponding normal (*greedy*) counterparts, but prefer the smallest number rather than the largest number of matches. See Section 9.7.3.5 for more detail.

**Note:** A quantifier cannot immediately follow another quantifier. A quantifier cannot begin an expression or subexpression or follow `^` or `|`.

**Table 9-14. Regular Expression Constraints**

Constraint	Description
<code>^</code>	matches at the beginning of the string
<code>\$</code>	matches at the end of the string
<code>(?=re)</code>	<i>positive lookahead</i> matches at any point where a substring matching <i>re</i> begins (AREs only)
<code>(?!re)</code>	<i>negative lookahead</i> matches at any point where no substring matching <i>re</i> begins (AREs only)

Lookahead constraints cannot contain *back references* (see Section 9.7.3.3), and all parentheses within them are considered non-capturing.

### 9.7.3.2. Bracket Expressions

A *bracket expression* is a list of characters enclosed in `[]`. It normally matches any single character from the list (but see below). If the list begins with `^`, it matches any single character *not* from the rest of the list. If two characters in the list are separated by `-`, this is shorthand for the full range of characters between those two (inclusive) in the collating sequence, e.g. `[0-9]` in ASCII matches any decimal digit. It is illegal for two ranges to share an endpoint, e.g. `a-c-e`. Ranges are very collating-sequence-dependent, so portable programs should avoid relying on them.

To include a literal `]` in the list, make it the first character (following a possible `^`). To include a literal `-`, make it the first or last character, or the second endpoint of a range. To use a literal `-` as the first endpoint of a range, enclose it in `[ .` and `. ]` to make it a collating element (see below). With the exception of these characters, some combinations using `[` (see next paragraphs), and escapes (AREs only), all other special characters lose their special significance within a bracket expression. In particular, `\` is not special when following ERE or BRE rules, though it is special (as introducing an escape) in AREs.

Within a bracket expression, a collating element (a character, a multiple-character sequence that collates as if it were a single character, or a collating-sequence name for either) enclosed in `[ .` and `. ]` stands for the sequence of characters of that collating element. The sequence is a single element of the bracket expression's list. A bracket expression containing a multiple-character collating element can thus match more than one character, e.g. if the collating sequence includes a `ch` collating element, then the RE `[ [ . ch . ] ] * c` matches the first five characters of `chchcc`.

**Note:** PostgreSQL currently has no multicharacter collating elements. This information describes possible future behavior.

Within a bracket expression, a collating element enclosed in [= and =] is an equivalence class, standing for the sequences of characters of all collating elements equivalent to that one, including itself. (If there are no other equivalent collating elements, the treatment is as if the enclosing delimiters were [. and .].) For example, if `o` and `^` are the members of an equivalence class, then `[ [=o=] ]`, `[ [=^=] ]`, and `[ o^ ]` are all synonymous. An equivalence class cannot be an endpoint of a range.

Within a bracket expression, the name of a character class enclosed in [: and :] stands for the list of all characters belonging to that class. Standard character class names are: `alnum`, `alpha`, `blank`, `cntrl`, `digit`, `graph`, `lower`, `print`, `punct`, `space`, `upper`, `xdigit`. These stand for the character classes defined in `ctype`. A locale can provide others. A character class cannot be used as an endpoint of a range.

There are two special cases of bracket expressions: the bracket expressions `[[:<:]]` and `[[:>:]]` are constraints, matching empty strings at the beginning and end of a word respectively. A word is defined as a sequence of word characters that is neither preceded nor followed by word characters. A word character is an `alnum` character (as defined by `ctype`) or an underscore. This is an extension, compatible with but not specified by POSIX 1003.2, and should be used with caution in software intended to be portable to other systems. The constraint escapes described below are usually preferable (they are no more standard, but are certainly easier to type).

### 9.7.3.3. Regular Expression Escapes

*Escapes* are special sequences beginning with `\` followed by an alphanumeric character. Escapes come in several varieties: character entry, class shorthands, constraint escapes, and back references. A `\` followed by an alphanumeric character but not constituting a valid escape is illegal in AREs. In EREs, there are no escapes: outside a bracket expression, a `\` followed by an alphanumeric character merely stands for that character as an ordinary character, and inside a bracket expression, `\` is an ordinary character. (The latter is the one actual incompatibility between EREs and AREs.)

*Character-entry escapes* exist to make it easier to specify non-printing and otherwise inconvenient characters in REs. They are shown in Table 9-15.

*Class-shorthand escapes* provide shorthands for certain commonly-used character classes. They are shown in Table 9-16.

A *constraint escape* is a constraint, matching the empty string if specific conditions are met, written as an escape. They are shown in Table 9-17.

A *back reference* (`\n`) matches the same string matched by the previous parenthesized subexpression specified by the number *n* (see Table 9-18). For example, `([bc])\1` matches `bb` or `cc` but not `bc` or `cb`. The subexpression must entirely precede the back reference in the RE. Subexpressions are numbered in the order of their leading parentheses. Non-capturing parentheses do not define subexpressions.

**Note:** Keep in mind that an escape's leading `\` will need to be doubled when entering the pattern as an SQL string constant. For example:

```
'123' ~ E'^\\d{3}' true
```

**Table 9-15. Regular Expression Character-Entry Escapes**

Escape	Description
<code>\a</code>	alert (bell) character, as in C
<code>\b</code>	backspace, as in C
<code>\B</code>	synonym for <code>\</code> to help reduce the need for backslash doubling
<code>\cX</code>	(where <i>X</i> is any character) the character whose low-order 5 bits are the same as those of <i>X</i> , and whose other bits are all zero
<code>\e</code>	the character whose collating-sequence name is <code>ESC</code> , or failing that, the character with octal value 033
<code>\f</code>	form feed, as in C
<code>\n</code>	newline, as in C
<code>\r</code>	carriage return, as in C
<code>\t</code>	horizontal tab, as in C
<code>\uwxxyz</code>	(where <i>wxyz</i> is exactly four hexadecimal digits) the UTF16 (Unicode, 16-bit) character <code>U+wxxyz</code> in the local byte ordering
<code>\Ustuvwxyz</code>	(where <i>stuvwxyz</i> is exactly eight hexadecimal digits) reserved for a somewhat-hypothetical Unicode extension to 32 bits
<code>\v</code>	vertical tab, as in C
<code>\xhhh</code>	(where <i>hhh</i> is any sequence of hexadecimal digits) the character whose hexadecimal value is <code>0xhhh</code> (a single character no matter how many hexadecimal digits are used)
<code>\0</code>	the character whose value is 0
<code>\xy</code>	(where <i>xy</i> is exactly two octal digits, and is not a <i>back reference</i> ) the character whose octal value is <code>0xy</code>
<code>\xyz</code>	(where <i>xyz</i> is exactly three octal digits, and is not a <i>back reference</i> ) the character whose octal value is <code>0xyz</code>

Hexadecimal digits are 0-9, a-f, and A-F. Octal digits are 0-7.

The character-entry escapes are always taken as ordinary characters. For example, `\135` is `]` in ASCII, but `\135` does not terminate a bracket expression.

**Table 9-16. Regular Expression Class-Shorthand Escapes**

Escape	Description
<code>\d</code>	<code>[[:digit:]]</code>
<code>\s</code>	<code>[[:space:]]</code>
<code>\w</code>	<code>[[:alnum:]]_</code> (note underscore is included)
<code>\D</code>	<code>[^[:digit:]]</code>
<code>\S</code>	<code>[^[:space:]]</code>
<code>\W</code>	<code>[^[:alnum:]]_</code> (note underscore is included)

Within bracket expressions, `\d`, `\s`, and `\w` lose their outer brackets, and `\D`, `\S`, and `\W` are illegal. (So, for example, `[a-c\d]` is equivalent to `[a-c[:digit:]]`. Also, `[a-c\D]`, which is equivalent to `[a-c^[[:digit:]]]`, is illegal.)

**Table 9-17. Regular Expression Constraint Escapes**

Escape	Description
<code>\A</code>	matches only at the beginning of the string (see Section 9.7.3.5 for how this differs from <code>^</code> )
<code>\m</code>	matches only at the beginning of a word
<code>\M</code>	matches only at the end of a word
<code>\y</code>	matches only at the beginning or end of a word
<code>\Y</code>	matches only at a point that is not the beginning or end of a word
<code>\Z</code>	matches only at the end of the string (see Section 9.7.3.5 for how this differs from <code>\$</code> )

A word is defined as in the specification of `[[:<:]]` and `[[:>:]]` above. Constraint escapes are illegal within bracket expressions.

**Table 9-18. Regular Expression Back References**

Escape	Description
<code>\m</code>	(where <i>m</i> is a nonzero digit) a back reference to the <i>m</i> 'th subexpression
<code>\mnn</code>	(where <i>m</i> is a nonzero digit, and <i>nn</i> is some more digits, and the decimal value <i>mnn</i> is not greater than the number of closing capturing parentheses seen so far) a back reference to the <i>mnn</i> 'th subexpression

**Note:** There is an inherent historical ambiguity between octal character-entry escapes and back references, which is resolved by heuristics, as hinted at above. A leading zero always indicates an octal escape. A single non-zero digit, not followed by another digit, is always taken as a back reference. A multidigit sequence not starting with a zero is taken as a back reference if it comes after a suitable subexpression (i.e. the number is in the legal range for a back reference), and otherwise is taken as octal.

### 9.7.3.4. Regular Expression Metasyntax

In addition to the main syntax described above, there are some special forms and miscellaneous syntactic facilities available.

Normally the flavor of RE being used is determined by `regex_flavor`. However, this can be overridden by a *director* prefix. If an RE begins with `***:`, the rest of the RE is taken as an ARE regardless of `regex_flavor`. If an RE begins with `***=`, the rest of the RE is taken to be a literal string, with all characters considered ordinary characters.

An ARE can begin with *embedded options*: a sequence `(?xyz)` (where `xyz` is one or more alphabetic characters) specifies options affecting the rest of the RE. These options override any previously determined options (including both the RE flavor and case sensitivity). The available option letters are shown in Table 9-19.

**Table 9-19. ARE Embedded-Option Letters**

Option	Description
b	rest of RE is a BRE
c	case-sensitive matching (overrides operator type)
e	rest of RE is an ERE
i	case-insensitive matching (see Section 9.7.3.5) (overrides operator type)
m	historical synonym for n
n	newline-sensitive matching (see Section 9.7.3.5)
p	partial newline-sensitive matching (see Section 9.7.3.5)
q	rest of RE is a literal (“quoted”) string, all ordinary characters
s	non-newline-sensitive matching (default)
t	tight syntax (default; see below)
w	inverse partial newline-sensitive (“weird”) matching (see Section 9.7.3.5)
x	expanded syntax (see below)

Embedded options take effect at the `)` terminating the sequence. They can appear only at the start of an ARE (after the `***:` director if any).

In addition to the usual (*tight*) RE syntax, in which all characters are significant, there is an *expanded* syntax, available by specifying the embedded `x` option. In the expanded syntax, white-space characters in the RE are ignored, as are all characters between a `#` and the following newline (or the end of the RE). This permits paragraphing and commenting a complex RE. There are three exceptions to that basic rule:

- a white-space character or `#` preceded by `\` is retained

- white space or # within a bracket expression is retained
- white space and comments cannot appear within multicharacter symbols, such as (? :

For this purpose, white-space characters are blank, tab, newline, and any character that belongs to the *space* character class.

Finally, in an ARE, outside bracket expressions, the sequence (?#*ttt*) (where *ttt* is any text not containing a *)*) is a comment, completely ignored. Again, this is not allowed between the characters of multicharacter symbols, like (? :. Such comments are more a historical artifact than a useful facility, and their use is deprecated; use the expanded syntax instead.

*None* of these metasyntax extensions is available if an initial \*\*\*= director has specified that the user's input be treated as a literal string rather than as an RE.

### 9.7.3.5. Regular Expression Matching Rules

In the event that an RE could match more than one substring of a given string, the RE matches the one starting earliest in the string. If the RE could match more than one substring starting at that point, either the longest possible match or the shortest possible match will be taken, depending on whether the RE is *greedy* or *non-greedy*.

Whether an RE is greedy or not is determined by the following rules:

- Most atoms, and all constraints, have no greediness attribute (because they cannot match variable amounts of text anyway).
- Adding parentheses around an RE does not change its greediness.
- A quantified atom with a fixed-repetition quantifier (*{m}* or *{m}?*) has the same greediness (possibly none) as the atom itself.
- A quantified atom with other normal quantifiers (including *{m, n}* with *m* equal to *n*) is greedy (prefers longest match).
- A quantified atom with a non-greedy quantifier (including *{m, n}?* with *m* equal to *n*) is non-greedy (prefers shortest match).
- A branch — that is, an RE that has no top-level | operator — has the same greediness as the first quantified atom in it that has a greediness attribute.
- An RE consisting of two or more branches connected by the | operator is always greedy.

The above rules associate greediness attributes not only with individual quantified atoms, but with branches and entire REs that contain quantified atoms. What that means is that the matching is done in such a way that the branch, or whole RE, matches the longest or shortest possible substring *as a whole*. Once the length of the entire match is determined, the part of it that matches any particular subexpression is determined on the basis of the greediness attribute of that subexpression, with subexpressions starting earlier in the RE taking priority over ones starting later.

An example of what this means:

```
SELECT SUBSTRING('XY1234Z', 'Y*([0-9]{1,3})');
Result: 123
```

```
SELECT SUBSTRING('XY1234Z', 'Y*?([0-9]{1,3})');
Result: 1
```

In the first case, the RE as a whole is greedy because `Y*` is greedy. It can match beginning at the `Y`, and it matches the longest possible string starting there, i.e., `Y123`. The output is the parenthesized part of that, or `123`. In the second case, the RE as a whole is non-greedy because `Y*?` is non-greedy. It can match beginning at the `Y`, and it matches the shortest possible string starting there, i.e., `Y1`. The subexpression `[0-9]{1,3}` is greedy but it cannot change the decision as to the overall match length; so it is forced to match just `1`.

In short, when an RE contains both greedy and non-greedy subexpressions, the total match length is either as long as possible or as short as possible, according to the attribute assigned to the whole RE. The attributes assigned to the subexpressions only affect how much of that match they are allowed to “eat” relative to each other.

The quantifiers `{1,1}` and `{1,1}?` can be used to force greediness or non-greediness, respectively, on a subexpression or a whole RE.

Match lengths are measured in characters, not collating elements. An empty string is considered longer than no match at all. For example: `bb*` matches the three middle characters of `abbbc`; `(week|wee)(night|knights)` matches all ten characters of `weeknights`; when `(.*)` is matched against `abc` the parenthesized subexpression matches all three characters; and when `(a*)` is matched against `bc` both the whole RE and the parenthesized subexpression match an empty string.

If case-independent matching is specified, the effect is much as if all case distinctions had vanished from the alphabet. When an alphabetic that exists in multiple cases appears as an ordinary character outside a bracket expression, it is effectively transformed into a bracket expression containing both cases, e.g. `x` becomes `[xX]`. When it appears inside a bracket expression, all case counterparts of it are added to the bracket expression, e.g. `[x]` becomes `[xX]` and `[^x]` becomes `[^xX]`.

If newline-sensitive matching is specified, `.` and bracket expressions using `^` will never match the newline character (so that matches will never cross newlines unless the RE explicitly arranges it) and `^` and `$` will match the empty string after and before a newline respectively, in addition to matching at beginning and end of string respectively. But the ARE escapes `\A` and `\Z` continue to match beginning or end of string *only*.

If partial newline-sensitive matching is specified, this affects `.` and bracket expressions as with newline-sensitive matching, but not `^` and `$`.

If inverse partial newline-sensitive matching is specified, this affects `^` and `$` as with newline-sensitive matching, but not `.` and bracket expressions. This isn’t very useful but is provided for symmetry.

### 9.7.3.6. Limits and Compatibility

No particular limit is imposed on the length of REs in this implementation. However, programs intended to be highly portable should not employ REs longer than 256 bytes, as a POSIX-compliant implementation can refuse to accept such REs.

The only feature of AREs that is actually incompatible with POSIX EREs is that `\` does not lose its special significance inside bracket expressions. All other ARE features use syntax which is illegal or has undefined or unspecified effects in POSIX EREs; the `***` syntax of directors likewise is outside the POSIX syntax for both BREs and EREs.

Many of the ARE extensions are borrowed from Perl, but some have been changed to clean them up, and a few Perl extensions are not present. Incompatibilities of note include `\b`, `\B`, the lack of special treatment for a trailing newline, the addition of complemented bracket expressions to the things affected by newline-sensitive matching, the restrictions on parentheses and back references in lookahead constraints, and the longest/shortest-match (rather than first-match) matching semantics.

Two significant incompatibilities exist between AREs and the ERE syntax recognized by pre-7.4 releases of PostgreSQL:

- In AREs, `\` followed by an alphanumeric character is either an escape or an error, while in previous releases, it was just another way of writing the alphanumeric. This should not be much of a problem because there was no reason to write such a sequence in earlier releases.
- In AREs, `\` remains a special character within `[]`, so a literal `\` within a bracket expression must be written `\\`.

While these differences are unlikely to create a problem for most applications, you can avoid them if necessary by setting `regex_flavor` to `extended`.

### 9.7.3.7. Basic Regular Expressions

BREs differ from EREs in several respects. `|`, `+`, and `?` are ordinary characters and there is no equivalent for their functionality. The delimiters for bounds are `\{` and `\}`, with `{` and `}` by themselves ordinary characters. The parentheses for nested subexpressions are `\(` and `\)`, with `(` and `)` by themselves ordinary characters. `^` is an ordinary character except at the beginning of the RE or the beginning of a parenthesized subexpression, `$` is an ordinary character except at the end of the RE or the end of a parenthesized subexpression, and `*` is an ordinary character if it appears at the beginning of the RE or the beginning of a parenthesized subexpression (after a possible leading `^`). Finally, single-digit back references are available, and `\<` and `\>` are synonyms for `[[:<:]]` and `[[:>:]]` respectively; no other escapes are available.

## 9.8. Data Type Formatting Functions

The PostgreSQL formatting functions provide a powerful set of tools for converting various data types (date/time, integer, floating point, numeric) to formatted strings and for converting from formatted strings to specific data types. Table 9-20 lists them. These functions all follow a common calling convention: the first argument is the value to be formatted and the second argument is a template that defines the output or input format.

The `to_timestamp` function can also take a single `double precision` argument to convert from Unix epoch to timestamp with time zone. (Integer Unix epochs are implicitly cast to double precision.)

**Table 9-20. Formatting Functions**

Function	Return Type	Description	Example
----------	-------------	-------------	---------

Function	Return Type	Description	Example
<code>to_char(timestamp, text)</code>	text	convert time stamp to string	<code>to_char(current_timestamp, 'HH12:MI:SS')</code>
<code>to_char(interval, text)</code>	text	convert interval to string	<code>to_char(interval '15h 2m 12s', 'HH24:MI:SS')</code>
<code>to_char(int, text)</code>	text	convert integer to string	<code>to_char(125, '999')</code>
<code>to_char(double precision, text)</code>	text	convert real/double precision to string	<code>to_char(125.8::real, '999D9')</code>
<code>to_char(numeric, text)</code>	text	convert numeric to string	<code>to_char(-125.8, '999D99S')</code>
<code>to_date(text, text)</code>	date	convert string to date	<code>to_date('05 Dec 2000', 'DD Mon YYYY')</code>
<code>to_number(text, text)</code>	numeric	convert string to numeric	<code>to_number('12,454.8-', '99G999D9S')</code>
<code>to_timestamp(text, text)</code>	timestamp with time zone	convert string to time stamp	<code>to_timestamp('05 Dec 2000', 'DD Mon YYYY')</code>
<code>to_timestamp(double precision)</code>	timestamp with time zone	convert UNIX epoch to time stamp	<code>to_timestamp(200120400)</code>

In an output template string (for `to_char`), there are certain patterns that are recognized and replaced with appropriately-formatted data from the value to be formatted. Any text that is not a template pattern is simply copied verbatim. Similarly, in an input template string (for anything but `to_char`), template patterns identify the parts of the input data string to be looked at and the values to be found there.

Table 9-21 shows the template patterns available for formatting date and time values.

**Table 9-21. Template Patterns for Date/Time Formatting**

Pattern	Description
HH	hour of day (01-12)
HH12	hour of day (01-12)
HH24	hour of day (00-23)
MI	minute (00-59)
SS	second (00-59)
MS	millisecond (000-999)
US	microsecond (000000-999999)
SSSS	seconds past midnight (0-86399)
AM or A.M. or PM or P.M.	meridian indicator (uppercase)
am or a.m. or pm or p.m.	meridian indicator (lowercase)
Y, YYYY	year (4 and more digits) with comma
YYYY	year (4 and more digits)
YYY	last 3 digits of year

Pattern	Description
YY	last 2 digits of year
Y	last digit of year
IYYY	ISO year (4 and more digits)
IYY	last 3 digits of ISO year
IY	last 2 digits of ISO year
I	last digit of ISO year
BC or B.C. or AD or A.D.	era indicator (uppercase)
bc or b.c. or ad or a.d.	era indicator (lowercase)
MONTH	full uppercase month name (blank-padded to 9 chars)
Month	full mixed-case month name (blank-padded to 9 chars)
month	full lowercase month name (blank-padded to 9 chars)
MON	abbreviated uppercase month name (3 chars in English, localized lengths vary)
Mon	abbreviated mixed-case month name (3 chars in English, localized lengths vary)
mon	abbreviated lowercase month name (3 chars in English, localized lengths vary)
MM	month number (01-12)
DAY	full uppercase day name (blank-padded to 9 chars)
Day	full mixed-case day name (blank-padded to 9 chars)
day	full lowercase day name (blank-padded to 9 chars)
DY	abbreviated uppercase day name (3 chars in English, localized lengths vary)
Dy	abbreviated mixed-case day name (3 chars in English, localized lengths vary)
dy	abbreviated lowercase day name (3 chars in English, localized lengths vary)
DDD	day of year (001-366)
IDDD	ISO day of year (001-371; day 1 of the year is Monday of the first ISO week.)
DD	day of month (01-31)
D	day of the week, Sunday(1) to Saturday(7)
ID	ISO day of the week, Monday(1) to Sunday(7)
W	week of month (1-5) (The first week starts on the first day of the month.)
WW	week number of year (1-53) (The first week starts on the first day of the year.)

Pattern	Description
IW	ISO week number of year (1 - 53; the first Thursday of the new year is in week 1.)
CC	century (2 digits) (The twenty-first century starts on 2001-01-01.)
J	Julian Day (days since November 24, 4714 BC at midnight)
Q	quarter
RM	month in Roman numerals (I-XII; I=January) (uppercase)
rm	month in Roman numerals (i-xii; i=January) (lowercase)
TZ	time-zone name (uppercase)
tz	time-zone name (lowercase)

Certain modifiers can be applied to any template pattern to alter its behavior. For example, `FMMonth` is the `Month` pattern with the `FM` modifier. Table 9-22 shows the modifier patterns for date/time formatting.

**Table 9-22. Template Pattern Modifiers for Date/Time Formatting**

Modifier	Description	Example
FM prefix	fill mode (suppress padding blanks and zeroes)	<code>FMMonth</code>
TH suffix	uppercase ordinal number suffix	<code>DDTH</code>
th suffix	lowercase ordinal number suffix	<code>DDth</code>
FX prefix	fixed format global option (see usage notes)	<code>FX Month DD Day</code>
TM prefix	translation mode (print localized day and month names based on <code>lc_messages</code> )	<code>TMMonth</code>
SP suffix	spell mode (not yet implemented)	<code>DDSP</code>

Usage notes for date/time formatting:

- `FM` suppresses leading zeroes and trailing blanks that would otherwise be added to make the output of a pattern be fixed-width.
- `TM` does not include trailing blanks.
- `to_timestamp` and `to_date` skip multiple blank spaces in the input string if the `FX` option is not used. `FX` must be specified as the first item in the template. For example `to_timestamp('2000 JUN', 'YYYY MON')` is correct, but `to_timestamp('2000 JUN', 'FXYYYY MON')` returns an error, because `to_timestamp` expects one space only.
- Ordinary text is allowed in `to_char` templates and will be output literally. You can put a substring

in double quotes to force it to be interpreted as literal text even if it contains pattern key words. For example, in `' "Hello Year "YYYY'`, the `YYYY` will be replaced by the year data, but the single `Y` in `Year` will not be.

- If you want to have a double quote in the output you must precede it with a backslash, for example `E'\\ "YYYY Month\\ "'`. (Two backslashes are necessary because the backslash already has a special meaning when using the escape string syntax.)
- The `YYYY` conversion from string to timestamp or date has a restriction if you use a year with more than 4 digits. You must use some non-digit character or template after `YYYY`, otherwise the year is always interpreted as 4 digits. For example (with the year 20000): `to_date('200001131', 'YYYYMMDD')` will be interpreted as a 4-digit year; instead use a non-digit separator after the year, like `to_date('20000-1131', 'YYYY-MMDD')` or `to_date('20000Nov31', 'YYYYMonDD')`.
- In conversions from string to timestamp or date, the `CC` field is ignored if there is a `YYY`, `YYYY` or `Y,YYY` field. If `CC` is used with `YY` or `Y` then the year is computed as  $(CC-1)*100+YY$ .
- An ISO week date (as distinct from a Gregorian date) can be specified to `to_timestamp` and `to_date` in one of two ways:
  - Year, week and weekday, for example `to_date('2006-42-4', 'IYYY-IW-ID')` returns the date 2006-10-19. If you omit the weekday it is assumed to be 1 (Monday).
  - Year and day of year, for example `to_date('2006-291', 'IYYY-IDDD')` also returns 2006-10-19.

Attempting to construct a date using a mixture of ISO week and Gregorian date fields is nonsensical, and could yield unexpected results. In the context of an ISO year, the concept of a 'month' or 'day of month' has no meaning. In the context of a Gregorian year, the ISO week has no meaning. Users should take care to keep Gregorian and ISO date specifications separate.

- Millisecond (`MS`) and microsecond (`US`) values in a conversion from string to timestamp are used as part of the seconds after the decimal point. For example `to_timestamp('12:3', 'SS:MS')` is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format `SS:MS`, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, one must use 12:003, which the conversion counts as 12 + 0.003 = 12.003 seconds. Here is a more complex example: `to_timestamp('15:12:02.020.001230', 'HH:MI:SS.MS.US')` is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.
- `to_char(..., 'ID')`'s day of the week numbering matches the `extract('isodow', ...)` function, but `to_char(..., 'D')`'s does not match `extract('dow', ...)`'s day numbering.
- `to_char(interval)` formats `HH` and `HH12` as hours in a single day, while `HH24` can output hours exceeding a single day, e.g. >24.

Table 9-23 shows the template patterns available for formatting numeric values.

**Table 9-23. Template Patterns for Numeric Formatting**

Pattern	Description
9	value with the specified number of digits

Pattern	Description
0	value with leading zeros
. (period)	decimal point
, (comma)	group (thousand) separator
PR	negative value in angle brackets
S	sign anchored to number (uses locale)
L	currency symbol (uses locale)
D	decimal point (uses locale)
G	group separator (uses locale)
MI	minus sign in specified position (if number < 0)
PL	plus sign in specified position (if number > 0)
SG	plus/minus sign in specified position
RN	roman numeral (input between 1 and 3999)
TH or th	ordinal number suffix
V	shift specified number of digits (see notes)
EEEE	scientific notation (not implemented yet)

Usage notes for numeric formatting:

- A sign formatted using SG, PL, or MI is not anchored to the number; for example, `to_char(-12, 'S9999')` produces ' -12', but `to_char(-12, 'MI9999')` produces '- 12'. The Oracle implementation does not allow the use of MI ahead of 9, but rather requires that 9 precede MI.
- 9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.
- TH does not convert values less than zero and does not convert fractional numbers.
- PL, SG, and TH are PostgreSQL extensions.
- V effectively multiplies the input values by  $10^n$ , where  $n$  is the number of digits following V. `to_char` does not support the use of V combined with a decimal point. (E.g., `99.9V99` is not allowed.)

Table 9-24 shows some examples of the use of the `to_char` function.

**Table 9-24. to\_char Examples**

Expression	Result
<code>to_char(current_timestamp, 'Day, DD HH12:MI:SS')</code>	'Tuesday , 06 05:39:18'
<code>to_char(current_timestamp, 'FMDay, FMDD HH12:MI:SS')</code>	'Tuesday, 6 05:39:18'
<code>to_char(-0.1, '99.99')</code>	' -.10'
<code>to_char(-0.1, 'FM9.99')</code>	'-.1'

Expression	Result
<code>to_char(0.1, '0.9')</code>	<code>' 0.1'</code>
<code>to_char(12, '9990999.9')</code>	<code>'      0012.0'</code>
<code>to_char(12, 'FM9990999.9')</code>	<code>'0012.'</code>
<code>to_char(485, '999')</code>	<code>' 485'</code>
<code>to_char(-485, '999')</code>	<code>'-485'</code>
<code>to_char(485, '9 9 9')</code>	<code>' 4 8 5'</code>
<code>to_char(1485, '9,999')</code>	<code>' 1,485'</code>
<code>to_char(1485, '9G999')</code>	<code>' 1 485'</code>
<code>to_char(148.5, '999.999')</code>	<code>' 148.500'</code>
<code>to_char(148.5, 'FM999.999')</code>	<code>'148.5'</code>
<code>to_char(148.5, 'FM999.990')</code>	<code>'148.500'</code>
<code>to_char(148.5, '999D999')</code>	<code>' 148,500'</code>
<code>to_char(3148.5, '9G999D999')</code>	<code>' 3 148,500'</code>
<code>to_char(-485, '999S')</code>	<code>'485-'</code>
<code>to_char(-485, '999MI')</code>	<code>'485-'</code>
<code>to_char(485, '999MI')</code>	<code>'485 '</code>
<code>to_char(485, 'FM999MI')</code>	<code>'485'</code>
<code>to_char(485, 'PL999')</code>	<code>' +485'</code>
<code>to_char(485, 'SG999')</code>	<code>' +485'</code>
<code>to_char(-485, 'SG999')</code>	<code>' -485'</code>
<code>to_char(-485, '9SG99')</code>	<code>' 4-85'</code>
<code>to_char(-485, '999PR')</code>	<code>' &lt;485 &gt;'</code>
<code>to_char(485, 'L999')</code>	<code>'DM 485'</code>
<code>to_char(485, 'RN')</code>	<code>'          CDLXXXV'</code>
<code>to_char(485, 'FMRN')</code>	<code>'CDLXXXV'</code>
<code>to_char(5.2, 'FMRN')</code>	<code>'V'</code>
<code>to_char(482, '999th')</code>	<code>' 482nd'</code>
<code>to_char(485, '"Good number:"999')</code>	<code>'Good number: 485'</code>
<code>to_char(485.8, ' "Pre:"999" Post:" .999')</code>	<code>'Pre: 485 Post: .800'</code>
<code>to_char(12, '99V999')</code>	<code>' 12000'</code>
<code>to_char(12.4, '99V999')</code>	<code>' 12400'</code>
<code>to_char(12.45, '99V9')</code>	<code>' 125'</code>

## 9.9. Date/Time Functions and Operators

Table 9-26 shows the available functions for date/time value processing, with details appearing in the following subsections. Table 9-25 illustrates the behaviors of the basic arithmetic operators (+, \*, etc.).

For formatting functions, refer to Section 9.8. You should be familiar with the background information on date/time data types from Section 8.5.

All the functions and operators described below that take `time` or `timestamp` inputs actually come in two variants: one that takes `time` with time zone or `timestamp` with time zone, and one that takes `time` without time zone or `timestamp` without time zone. For brevity, these variants are not shown separately. Also, the `+` and `*` operators come in commutative pairs (for example both `date + integer` and `integer + date`); we show only one of each such pair.

**Table 9-25. Date/Time Operators**

Operator	Example	Result
<code>+</code>	<code>date '2001-09-28' + integer '7'</code>	<code>date '2001-10-05'</code>
<code>+</code>	<code>date '2001-09-28' + interval '1 hour'</code>	<code>timestamp '2001-09-28 01:00:00'</code>
<code>+</code>	<code>date '2001-09-28' + time '03:00'</code>	<code>timestamp '2001-09-28 03:00:00'</code>
<code>+</code>	<code>interval '1 day' + interval '1 hour'</code>	<code>interval '1 day 01:00:00'</code>
<code>+</code>	<code>timestamp '2001-09-28 01:00' + interval '23 hours'</code>	<code>timestamp '2001-09-29 00:00:00'</code>
<code>+</code>	<code>time '01:00' + interval '3 hours'</code>	<code>time '04:00:00'</code>
<code>-</code>	<code>- interval '23 hours'</code>	<code>interval '-23:00:00'</code>
<code>-</code>	<code>date '2001-10-01' - date '2001-09-28'</code>	<code>integer '3'</code>
<code>-</code>	<code>date '2001-10-01' - integer '7'</code>	<code>date '2001-09-24'</code>
<code>-</code>	<code>date '2001-09-28' - interval '1 hour'</code>	<code>timestamp '2001-09-27 23:00:00'</code>
<code>-</code>	<code>time '05:00' - time '03:00'</code>	<code>interval '02:00:00'</code>
<code>-</code>	<code>time '05:00' - interval '2 hours'</code>	<code>time '03:00:00'</code>
<code>-</code>	<code>timestamp '2001-09-28 23:00' - interval '23 hours'</code>	<code>timestamp '2001-09-28 00:00:00'</code>
<code>-</code>	<code>interval '1 day' - interval '1 hour'</code>	<code>interval '1 day -01:00:00'</code>
<code>-</code>	<code>timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00'</code>	<code>interval '1 day 15:00:00'</code>

Operator	Example	Result
*	900 * interval '1 second'	interval '00:15:00'
*	21 * interval '1 day'	interval '21 days'
*	double precision '3.5' * interval '1 hour'	interval '03:30:00'
/	interval '1 hour' / double precision '1.5'	interval '00:40:00'

Table 9-26. Date/Time Functions

Function	Return Type	Description	Example	Result
age(timestamp, timestamp)	interval	Subtract arguments, producing a “symbolic” result that uses years and months	age(timestamp '2001-04-10', timestamp '1957-06-13')	43 years 9 mons 27 days
age(timestamp)	interval	Subtract from current_date	age(timestamp '1957-06-13')	43 years 8 mons 3 days
clock_timestamp()	timestamp with time zone	Current date and time (changes during statement execution); see Section 9.9.4		
current_date	date	Current date; see Section 9.9.4		
current_time	time with time zone	Current time of day; see Section 9.9.4		
current_timestamp	timestamp with time zone	Current date and time (start of current transaction); see Section 9.9.4		
date_part(text, timestamp)	double precision	Get subfield (equivalent to extract); see Section 9.9.1	date_part('hour', timestamp '2001-02-16 20:38:40')	20
date_part(text, interval)	double precision	Get subfield (equivalent to extract); see Section 9.9.1	date_part('month', interval '2 years 3 months')	3

Function	Return Type	Description	Example	Result
<code>date_trunc(text, timestamp)</code>	timestamp	Truncate to specified precision; see also Section 9.9.2	<code>date_trunc('hour', timestamp '2001-02-16 20:38:40')</code>	2001-02-16 20:00:00
<code>extract(field from timestamp)</code>	double precision	Get subfield; see Section 9.9.1	<code>extract(hour from timestamp '2001-02-16 20:38:40')</code>	20
<code>extract(field from interval)</code>	double precision	Get subfield; see Section 9.9.1	<code>extract(month from interval '2 years 3 months')</code>	3
<code>isfinite(timestamp)</code>	boolean	Test for finite time stamp (not equal to infinity)	<code>isfinite(timestamp '2001-02-16 21:28:30')</code>	true
<code>isfinite(interval)</code>	boolean	Test for finite interval	<code>isfinite(interval '4 hours')</code>	true
<code>justify_days(interval)</code>	interval	Adjust interval so 30-day time periods are represented as months	<code>justify_days(interval '30 days')</code>	1 month
<code>justify_hours(interval)</code>	interval	Adjust interval so 24-hour time periods are represented as days	<code>justify_hours(interval '24 hours')</code>	1 day
<code>justify_interval(interval)</code>	interval	Adjust interval using <code>justify_days</code> and <code>justify_hours</code> , with additional sign adjustments	<code>justify_interval('1 mon -1 hour')</code>	129 days 23:00:00
<code>localtime</code>	time	Current time of day; see Section 9.9.4		
<code>localtimestamp</code>	timestamp	Current date and time (start of current transaction); see Section 9.9.4		

Function	Return Type	Description	Example	Result
<code>now()</code>	timestamp with time zone	Current date and time (start of current transaction); see Section 9.9.4		
<code>statement_timestamp()</code>	timestamp with time zone	Current date and time (start of current statement); see Section 9.9.4		
<code>timeofday()</code>	text	Current date and time (like <code>clock_timestamp()</code> , but as a text string); see Section 9.9.4		
<code>transaction_timestamp()</code>	timestamp with time zone	Current date and time (start of current transaction); see Section 9.9.4		

In addition to these functions, the SQL `OVERLAPS` operator is supported:

```
(start1, end1) OVERLAPS (start2, end2)
(start1, length1) OVERLAPS (start2, length2)
```

This expression yields true when two time periods (defined by their endpoints) overlap, false when they do not overlap. The endpoints can be specified as pairs of dates, times, or time stamps; or as a date, time, or time stamp followed by an interval.

```
SELECT (DATE '2001-02-16', DATE '2001-12-21') OVERLAPS
       (DATE '2001-10-30', DATE '2002-10-30');
Result: true
SELECT (DATE '2001-02-16', INTERVAL '100 days') OVERLAPS
       (DATE '2001-10-30', DATE '2002-10-30');
Result: false
```

When adding an interval value to (or subtracting an interval value from) a timestamp with time zone value, the days component advances (or decrements) the date of the timestamp with time zone by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means interval '1 day' does not necessarily equal interval '24 hours'. For example, with the session time zone set to `CST7CDT`, timestamp with time zone '2005-04-02 12:00-07' + interval '1 day' will produce timestamp with time zone '2005-04-03 12:00-06', while adding interval '24 hours' to the same initial timestamp with time zone produces timestamp with time zone '2005-04-03 13:00-06', as there is a change in daylight saving time at 2005-04-03 02:00 in time zone `CST7CDT`.

Note there can be ambiguity in the `months` returned by `age` because different months have a different number of days. PostgreSQL's approach uses the month from the earlier of the two dates when calculating partial months. For example, `age('2004-06-01', '2004-04-30')` uses April to yield `1 mon 1 day`, while using May would yield `1 mon 2 days` because May has 31 days, while April has only 30.

### 9.9.1. `EXTRACT, date_part`

`EXTRACT(field FROM source)`

The `extract` function retrieves subfields such as year or hour from date/time values. *source* must be a value expression of type `timestamp`, `time`, or `interval`. (Expressions of type `date` will be cast to `timestamp` and can therefore be used as well.) *field* is an identifier or string that selects what field to extract from the source value. The `extract` function returns values of type `double precision`. The following are valid field names:

`century`

The century

```
SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
Result: 20
SELECT EXTRACT(CENTURY FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 21
```

The first century starts at 0001-01-01 00:00:00 AD, although they did not know it at the time. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1. If you disagree with this, please write your complaint to: Pope, Cathedral Saint-Peter of Roma, Vatican.

PostgreSQL releases before 8.0 did not follow the conventional numbering of centuries, but just returned the year field divided by 100.

`day`

The day (of the month) field (1 - 31)

```
SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 16
```

`decade`

The year field divided by 10

```
SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 200
```

`dow`

The day of the week as Sunday(0) to Saturday(6)

```
SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 5
```

Note that `extract`'s day of the week numbering is different from that of the `to_char(..., 'D')` function.

day

The day of the year (1 - 365/366)

```
SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 47
```

epoch

For date and timestamp values, the number of seconds since 1970-01-01 00:00:00-00 (can be negative); for interval values, the total number of seconds in the interval

```
SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40-08');
Result: 982384720
```

```
SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
Result: 442800
```

Here is how you can convert an epoch value back to a time stamp:

```
SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720 * INTERVAL '1 second';
```

hour

The hour field (0 - 23)

```
SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 20
```

isodow

The day of the week as Monday(1) to Sunday(7)

```
SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
Result: 7
```

This is identical to `dow` except for Sunday. This matches the ISO 8601 day of the week numbering.

isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

```
SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
Result: 2005
SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
Result: 2006
```

Each ISO year begins with the Monday of the week containing the 4th of January, so in early January or late December the ISO year may be different from the Gregorian year. See the `week` field for more information.

This field is not available in PostgreSQL releases prior to 8.3.

microseconds

The seconds field, including fractional parts, multiplied by 1 000 000. Note that this includes full seconds.

```
SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
Result: 28500000
```

## millennium

**The millennium**

```
SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
```

*Result:* 3

Years in the 1900s are in the second millennium. The third millennium starts January 1, 2001.

PostgreSQL releases before 8.0 did not follow the conventional numbering of millennia, but just returned the year field divided by 1000.

## milliseconds

The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.

```
SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
```

*Result:* 28500

## minute

**The minutes field (0 - 59)**

```
SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
```

*Result:* 38

## month

For timestamp values, the number of the month within the year (1 - 12) ; for interval values the number of months, modulo 12 (0 - 11)

```
SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
```

*Result:* 2

```
SELECT EXTRACT(MONTH FROM INTERVAL '2 years 3 months');
```

*Result:* 3

```
SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
```

*Result:* 1

## quarter

**The quarter of the year (1 - 4) that the day is in**

```
SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
```

*Result:* 1

## second

**The seconds field, including fractional parts (0 - 59<sup>1</sup>)**

```
SELECT EXTRACT(SECOND FROM TIMESTAMP '2001-02-16 20:38:40');
```

*Result:* 40

```
SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
```

*Result:* 28.5

## timezone

The time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

---

<sup>1</sup>60 if leap seconds are implemented by the operating system

`timezone_hour`

The hour component of the time zone offset

`timezone_minute`

The minute component of the time zone offset

`week`

The number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year. For example, 2005-01-01 is part of the 53rd week of year 2004, and 2006-01-01 is part of the 52nd week of year 2005.

```
SELECT EXTRACT(WEEK FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 7
```

`year`

The year field. Keep in mind there is no 0 AD, so subtracting BC years from AD years should be done with care.

```
SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
Result: 2001
```

The `extract` function is primarily intended for computational processing. For formatting date/time values for display, see Section 9.8.

The `date_part` function is modeled on the traditional Ingres equivalent to the SQL-standard function `extract`:

```
date_part('field', source)
```

Note that here the *field* parameter needs to be a string value, not a name. The valid field names for `date_part` are the same as for `extract`.

```
SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
Result: 16
```

```
SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
Result: 4
```

## 9.9.2. `date_trunc`

The function `date_trunc` is conceptually similar to the `trunc` function for numbers.

```
date_trunc('field', source)
```

*source* is a value expression of type `timestamp` or `interval`. (Values of type `date` and `time` are cast automatically, to `timestamp` or `interval` respectively.) *field* selects to which precision to truncate the

input value. The return value is of type `timestamp` or `interval` with all fields that are less significant than the selected one set to zero (or one, for day and month).

Valid values for *field* are:

```

microseconds
milliseconds
second
minute
hour
day
week
month
quarter
year
decade
century
millennium

```

Examples:

```

SELECT date_trunc('hour', TIMESTAMP '2001-02-16 20:38:40');
Result: 2001-02-16 20:00:00

```

```

SELECT date_trunc('year', TIMESTAMP '2001-02-16 20:38:40');
Result: 2001-01-01 00:00:00

```

### 9.9.3. AT TIME ZONE

The `AT TIME ZONE` construct allows conversions of time stamps to different time zones. Table 9-27 shows its variants.

**Table 9-27. AT TIME ZONE Variants**

Expression	Return Type	Description
<code>timestamp without time zone</code> <code>AT TIME ZONE zone</code>	<code>timestamp with time zone</code>	Treat given time stamp <i>without time zone</i> as located in the specified time zone
<code>timestamp with time zone</code> <code>AT TIME ZONE zone</code>	<code>timestamp without time zone</code>	Convert given time stamp <i>with time zone</i> to the new time zone
<code>time with time zone AT</code> <code>TIME ZONE zone</code>	<code>time with time zone</code>	Convert given time <i>with time zone</i> to the new time zone

In these expressions, the desired time zone *zone* can be specified either as a text string (e.g., `'PST'`) or as an interval (e.g., `INTERVAL '-08:00'`). In the text case, a time zone name can be specified in any of

the ways described in Section 8.5.3.

Examples (supposing that the local time zone is PST8PDT):

```
SELECT TIMESTAMP '2001-02-16 20:38:40' AT TIME ZONE 'MST';
Result: 2001-02-16 19:38:40-08
```

```
SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40-05' AT TIME ZONE 'MST';
Result: 2001-02-16 18:38:40
```

The first example takes a time stamp without time zone and interprets it as MST time (UTC-7), which is then converted to PST (UTC-8) for display. The second example takes a time stamp specified in EST (UTC-5) and converts it to local time in MST (UTC-7).

The function `timezone(zone, timestamp)` is equivalent to the SQL-conforming construct `timestamp AT TIME ZONE zone`.

### 9.9.4. Current Date/Time

PostgreSQL provides a number of functions that return values related to the current date and time. These SQL-standard functions all return values based on the start time of the current transaction:

```
CURRENT_DATE
CURRENT_TIME
CURRENT_TIMESTAMP
CURRENT_TIME (precision)
CURRENT_TIMESTAMP (precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME (precision)
LOCALTIMESTAMP (precision)
```

`CURRENT_TIME` and `CURRENT_TIMESTAMP` deliver values with time zone; `LOCALTIME` and `LOCALTIMESTAMP` deliver values without time zone.

`CURRENT_TIME`, `CURRENT_TIMESTAMP`, `LOCALTIME`, and `LOCALTIMESTAMP` can optionally be given a precision parameter, which causes the result to be rounded to that many fractional digits in the seconds field. Without a precision parameter, the result is given to the full available precision.

Some examples:

```
SELECT CURRENT_TIME;
Result: 14:39:53.662522-05
```

```
SELECT CURRENT_DATE;
Result: 2001-12-23
```

```
SELECT CURRENT_TIMESTAMP;
Result: 2001-12-23 14:39:53.662522-05
```

```
SELECT CURRENT_TIMESTAMP (2);
```

```
Result: 2001-12-23 14:39:53.66-05
```

```
SELECT LOCALTIMESTAMP;
```

```
Result: 2001-12-23 14:39:53.662522
```

Since these functions return the start time of the current transaction, their values do not change during the transaction. This is considered a feature: the intent is to allow a single transaction to have a consistent notion of the “current” time, so that multiple modifications within the same transaction bear the same time stamp.

**Note:** Other database systems might advance these values more frequently.

PostgreSQL also provides functions that return the start time of the current statement, as well as the actual current time at the instant the function is called. The complete list of non-SQL-standard time functions is:

```
now()
transaction_timestamp()
statement_timestamp()
clock_timestamp()
timeofday()
```

`now()` is a traditional PostgreSQL equivalent to `CURRENT_TIMESTAMP`. `transaction_timestamp()` is likewise equivalent to `CURRENT_TIMESTAMP`, but is named to clearly reflect what it returns. `statement_timestamp()` returns the start time of the current statement (more specifically, the time of receipt of the latest command message from the client). `statement_timestamp()` and `transaction_timestamp()` return the same value during the first command of a transaction, but might differ during subsequent commands. `clock_timestamp()` returns the actual current time, and therefore its value changes even within a single SQL command. `timeofday()` is a historical PostgreSQL function. Like `clock_timestamp()`, it returns the actual current time, but as a formatted text string rather than a timestamp with time zone value.

All the date/time data types also accept the special literal value `now` to specify the current date and time (again, interpreted as the transaction start time). Thus, the following three all return the same result:

```
SELECT CURRENT_TIMESTAMP;
SELECT now();
SELECT TIMESTAMP 'now'; -- incorrect for use with DEFAULT
```

**Tip:** You do not want to use the third form when specifying a `DEFAULT` clause while creating a table. The system will convert `now` to a `timestamp` as soon as the constant is parsed, so that when the default value is needed, the time of the table creation would be used! The first two forms will not be evaluated until the default value is used, because they are function calls. Thus they will give the desired behavior of defaulting to the time of row insertion.

### 9.9.5. Delaying Execution

The following function is available to delay execution of the server process:

`pg_sleep(seconds)`

`pg_sleep` makes the current session's process sleep until *seconds* seconds have elapsed. *seconds* is a value of type `double precision`, so fractional-second delays can be specified. For example:

```
SELECT pg_sleep(1.5);
```

**Note:** The effective resolution of the sleep interval is platform-specific; 0.01 seconds is a common value. The sleep delay will be at least as long as specified. It might be longer depending on factors such as server load.

#### Warning

Make sure that your session does not hold more locks than necessary when calling `pg_sleep`. Otherwise other sessions might have to wait for your sleeping process, slowing down the entire system.

## 9.10. Enum Support Functions

For enum types (described in Section 8.7), there are several functions that allow cleaner programming without hard-coding particular values of an enum type. These are listed in Table 9-28. The examples assume an enum type created as:

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
```

Table 9-28. Enum Support Functions

Function	Description	Example	Example Result
<code>enum_first(anyenum)</code>	Returns the first value of the input enum type	<code>enum_first(null::rainbow)</code>	<code>red</code>
<code>enum_last(anyenum)</code>	Returns the last value of the input enum type	<code>enum_last(null::rainbow)</code>	<code>purple</code>
<code>enum_range(anyenum)</code>	Returns all values of the input enum type in an ordered array	<code>enum_range(null::rainbow)</code>	<code>{red,orange,yellow,green,blue,purple}</code>

Function	Description	Example	Example Result
enum_range(anyenum, anyenum)	Returns the range between the two given enum values, as an ordered array. The values must be from the same enum type. If the first parameter is null, the result will start with the first value of the enum type. If the second parameter is null, the result will end with the last value of the enum type.	enum_range('orange'::rainbow, 'green'::rainbow)	{orange, yellow, green}
		enum_range(NULL, 'green'::rainbow)	{red, orange, yellow, green}
		enum_range('orange'::rainbow, NULL)	{orange, yellow, green, blue, purple}

Notice that except for the two-argument form of `enum_range`, these functions disregard the specific value passed to them; they care only about its declared data type. Either null or a specific value of the type can be passed, with the same result. It is more common to apply these functions to a table column or function argument than to a hardwired type name as suggested by the examples.

## 9.11. Geometric Functions and Operators

The geometric types `point`, `box`, `lseg`, `line`, `path`, `polygon`, and `circle` have a large set of native support functions and operators, shown in Table 9-29, Table 9-30, and Table 9-31.

Caution

Note that the “same as” operator, `~=`, represents the usual notion of equality for the `point`, `box`, `polygon`, and `circle` types. Some of these types also have an `=` operator, but `=` compares for equal *areas* only. The other scalar comparison operators (`<=` and so on) likewise compare areas for these types.

Table 9-29. Geometric Operators

Operator	Description	Example
+	Translation	<code>box '((0,0),(1,1))' + point '(2.0,0)'</code>
-	Translation	<code>box '((0,0),(1,1))' - point '(2.0,0)'</code>
*	Scaling/rotation	<code>box '((0,0),(1,1))' * point '(2.0,0)'</code>

Operator	Description	Example
/	Scaling/rotation	box ' ((0,0), (2,2)) ' / point ' (2.0,0) '
#	Point or box of intersection	' ((1,-1), (-1,1)) ' # ' ((1,1), (-1,-1)) '
#	Number of points in path or polygon	# ' ((1,0), (0,1), (-1,0)) '
@-@	Length or circumference	@-@ path ' ((0,0), (1,0)) '
@@	Center	@@ circle ' ((0,0), 10) '
##	Closest point to first operand on second operand	point ' (0,0) ' ## lseg ' ((2,0), (0,2)) '
<->	Distance between	circle ' ((0,0), 1) ' <-> circle ' ((5,0), 1) '
&&	Overlaps?	box ' ((0,0), (1,1)) ' && box ' ((0,0), (2,2)) '
<<	Is strictly left of?	circle ' ((0,0), 1) ' << circle ' ((5,0), 1) '
>>	Is strictly right of?	circle ' ((5,0), 1) ' >> circle ' ((0,0), 1) '
&<	Does not extend to the right of?	box ' ((0,0), (1,1)) ' &< box ' ((0,0), (2,2)) '
&>	Does not extend to the left of?	box ' ((0,0), (3,3)) ' &> box ' ((0,0), (2,2)) '
<<	Is strictly below?	box ' ((0,0), (3,3)) ' <<  box ' ((3,4), (5,5)) '
>>	Is strictly above?	box ' ((3,4), (5,5)) '  >> box ' ((0,0), (3,3)) '
&<	Does not extend above?	box ' ((0,0), (1,1)) ' &<  box ' ((0,0), (2,2)) '
&>	Does not extend below?	box ' ((0,0), (3,3)) '  &> box ' ((0,0), (2,2)) '
<^	Is below (allows touching)?	circle ' ((0,0), 1) ' <^ circle ' ((0,5), 1) '
>^	Is above (allows touching)?	circle ' ((0,5), 1) ' >^ circle ' ((0,0), 1) '
?#	Intersects?	lseg ' ((-1,0), (1,0)) ' ?# box ' ((-2,-2), (2,2)) '
?-	Is horizontal?	?- lseg ' ((-1,0), (1,0)) '
?-	Are horizontally aligned?	point ' (1,0) ' ?- point ' (0,0) '
?	Is vertical?	?  lseg ' ((-1,0), (1,0)) '
?	Are vertically aligned?	point ' (0,1) ' ?  point ' (0,0) '

Operator	Description	Example
?-	Is perpendicular?	<code>lseg ' ( (0,0), (0,1)) ' ?- </code> <code>lseg ' ( (0,0), (1,0)) '</code>
?	Are parallel?	<code>lseg ' ( (-1,0), (1,0)) '</code> <code>?   lseg</code> <code>' ( (-1,2), (1,2)) '</code>
@>	Contains?	<code>circle ' ( (0,0), 2) ' @&gt;</code> <code>point ' (1,1) '</code>
<@	Contained in or on?	<code>point ' (1,1) ' &lt;@ circle</code> <code>' ( (0,0), 2) '</code>
~=	Same as?	<code>polygon ' ( (0,0), (1,1)) '</code> <code>~= polygon</code> <code>' ( (1,1), (0,0)) '</code>

**Note:** Before PostgreSQL 8.2, the containment operators @> and <@ were respectively called ~ and @. These names are still available, but are deprecated and will eventually be retired.

Table 9-30. Geometric Functions

Function	Return Type	Description	Example
<code>area(object)</code>	double precision	area	<code>area(box</code> <code>' ( (0,0), (1,1)) ')</code>
<code>center(object)</code>	point	center	<code>center(box</code> <code>' ( (0,0), (1,2)) ')</code>
<code>diameter(circle)</code>	double precision	diameter of circle	<code>diameter(circle</code> <code>' ( (0,0), 2.0) ')</code>
<code>height(box)</code>	double precision	vertical size of box	<code>height(box</code> <code>' ( (0,0), (1,1)) ')</code>
<code>isclosed(path)</code>	boolean	a closed path?	<code>isclosed(path</code> <code>' ( (0,0), (1,1), (2,0)) ')</code>
<code>isopen(path)</code>	boolean	an open path?	<code>isopen(path</code> <code>' [ (0,0), (1,1), (2,0)] ')</code>
<code>length(object)</code>	double precision	length	<code>length(path</code> <code>' ( (-1,0), (1,0)) ')</code>
<code>npoints(path)</code>	int	number of points	<code>npoints(path</code> <code>' [ (0,0), (1,1), (2,0)] ')</code>
<code>npoints(polygon)</code>	int	number of points	<code>npoints(polygon</code> <code>' ( (1,1), (0,0)) ')</code>

Function	Return Type	Description	Example
<code>pclose(path)</code>	path	convert path to closed	<code>pclose(path ' [(0,0), (1,1), (2,0)]')</code>
<code>popen(path)</code>	path	convert path to open	<code>popen(path ' ((0,0), (1,1), (2,0))')</code>
<code>radius(circle)</code>	double precision	radius of circle	<code>radius(circle ' ((0,0), 2.0)')</code>
<code>width(box)</code>	double precision	horizontal size of box	<code>width(box ' ((0,0), (1,1))')</code>

**Table 9-31. Geometric Type Conversion Functions**

Function	Return Type	Description	Example
<code>box(circle)</code>	box	circle to box	<code>box(circle ' ((0,0), 2.0)')</code>
<code>box(point, point)</code>	box	points to box	<code>box(point ' (0,0)', point ' (1,1)')</code>
<code>box(polygon)</code>	box	polygon to box	<code>box(polygon ' ((0,0), (1,1), (2,0))')</code>
<code>circle(box)</code>	circle	box to circle	<code>circle(box ' ((0,0), (1,1))')</code>
<code>circle(point, double precision)</code>	circle	center and radius to circle	<code>circle(point ' (0,0)', 2.0)</code>
<code>circle(polygon)</code>	circle	polygon to circle	<code>circle(polygon ' ((0,0), (1,1), (2,0))')</code>
<code>lseg(box)</code>	lseg	box diagonal to line segment	<code>lseg(box ' ((-1,0), (1,0))')</code>
<code>lseg(point, point)</code>	lseg	points to line segment	<code>lseg(point ' (-1,0)', point ' (1,0)')</code>
<code>path(polygon)</code>	point	polygon to path	<code>path(polygon ' ((0,0), (1,1), (2,0))')</code>
<code>point(double precision, double precision)</code>	point	construct point	<code>point(23.4, -44.5)</code>
<code>point(box)</code>	point	center of box	<code>point(box ' ((-1,0), (1,0))')</code>
<code>point(circle)</code>	point	center of circle	<code>point(circle ' ((0,0), 2.0)')</code>

Function	Return Type	Description	Example
<code>point(lseg)</code>	point	center of line segment	<code>point(lseg '((-1,0),(1,0))')</code>
<code>point(polygon)</code>	point	center of polygon	<code>point(polygon '((0,0),(1,1),(2,0)))'</code>
<code>polygon(box)</code>	polygon	box to 4-point polygon	<code>polygon(box '((0,0),(1,1)))'</code>
<code>polygon(circle)</code>	polygon	circle to 12-point polygon	<code>polygon(circle '((0,0),2.0)')</code>
<code>polygon(npts, circle)</code>	polygon	circle to <i>npts</i> -point polygon	<code>polygon(12, circle '((0,0),2.0)')</code>
<code>polygon(path)</code>	polygon	path to polygon	<code>polygon(path '((0,0),(1,1),(2,0)))'</code>

It is possible to access the two component numbers of a `point` as though it were an array with indices 0 and 1. For example, if `t.p` is a `point` column then `SELECT p[0] FROM t` retrieves the X coordinate and `UPDATE t SET p[1] = ...` changes the Y coordinate. In the same way, a value of type `box` or `lseg` can be treated as an array of two point values.

The `area` function works for the types `box`, `circle`, and `path`. The `area` function only works on the `path` data type if the points in the `path` are non-intersecting. For example, the `path '((0,0),(0,1),(2,1),(2,2),(1,2),(1,0),(0,0))':PATH` won't work, however, the following visually identical `path '((0,0),(0,1),(1,1),(1,2),(2,2),(2,1),(1,1),(1,0),(0,0))':PATH` will work. If the concept of an intersecting versus non-intersecting path is confusing, draw both of the above paths side by side on a piece of graph paper.

## 9.12. Network Address Functions and Operators

Table 9-32 shows the operators available for the `cidr` and `inet` types. The operators `<<`, `<=<`, `>>`, and `>>=` test for subnet inclusion. They consider only the network parts of the two addresses, ignoring any host part, and determine whether one network part is identical to or a subnet of the other.

**Table 9-32. `cidr` and `inet` Operators**

Operator	Description	Example
<code>&lt;</code>	is less than	<code>inet '192.168.1.5' &lt; inet '192.168.1.6'</code>
<code>&lt;=</code>	is less than or equal	<code>inet '192.168.1.5' &lt;= inet '192.168.1.5'</code>
<code>=</code>	equals	<code>inet '192.168.1.5' = inet '192.168.1.5'</code>

Operator	Description	Example
>=	is greater or equal	inet '192.168.1.5' >= inet '192.168.1.5'
>	is greater than	inet '192.168.1.5' > inet '192.168.1.4'
<>	is not equal	inet '192.168.1.5' <> inet '192.168.1.4'
<<	is contained within	inet '192.168.1.5' << inet '192.168.1/24'
<<=	is contained within or equals	inet '192.168.1/24' <<= inet '192.168.1/24'
>>	contains	inet '192.168.1/24' >> inet '192.168.1.5'
>>=	contains or equals	inet '192.168.1/24' >>= inet '192.168.1/24'
~	bitwise NOT	~ inet '192.168.1.6'
&	bitwise AND	inet '192.168.1.6' & inet '0.0.0.255'
	bitwise OR	inet '192.168.1.6'   inet '0.0.0.255'
+	addition	inet '192.168.1.6' + 25
-	subtraction	inet '192.168.1.43' - 36
-	subtraction	inet '192.168.1.43' - inet '192.168.1.19'

Table 9-33 shows the functions available for use with the `cidr` and `inet` types. The `host`, `text`, and `abbrev` functions are primarily intended to offer alternative display formats.

**Table 9-33. `cidr` and `inet` Functions**

Function	Return Type	Description	Example	Result
<code>abbrev(inet)</code>	text	abbreviated display format as text	<code>abbrev(inet '10.1.0.0/16')</code>	10.1.0.0/16
<code>abbrev(cidr)</code>	text	abbreviated display format as text	<code>abbrev(cidr '10.1.0.0/16')</code>	10.1/16
<code>broadcast(inet)</code>	inet	broadcast address for network	<code>broadcast('192.168.1.5/24')</code>	192.168.255.254
<code>family(inet)</code>	int	extract family of address; 4 for IPv4, 6 for IPv6	<code>family('::1')</code>	6
<code>host(inet)</code>	text	extract IP address as text	<code>host('192.168.1.59/24')</code>	192.168.1.5
<code>hostmask(inet)</code>	inet	construct host mask for network	<code>hostmask('192.168.0.0/30')</code>	192.168.0.255

Function	Return Type	Description	Example	Result
<code>masklen(inet)</code>	<code>int</code>	extract netmask length	<code>masklen('192.168.1.5/24')</code>	24
<code>netmask(inet)</code>	<code>inet</code>	construct netmask for network	<code>netmask('192.168.1.5/24')</code>	255.255.255.0
<code>network(inet)</code>	<code>cidr</code>	extract network part of address	<code>network('192.168.1.5/24')</code>	192.168.1.0/24
<code>set_masklen(inet, int)</code>	<code>inet</code>	set netmask length for <code>inet</code> value	<code>set_masklen('192.168.1.5', 16)</code>	192.168.1.5/16
<code>set_masklen(cidr, int)</code>	<code>cidr</code>	set netmask length for <code>cidr</code> value	<code>set_masklen('192.168.1.5/24', 16)</code>	192.168.1.5/16
<code>text(inet)</code>	<code>text</code>	extract IP address and netmask length as text	<code>text(inet '192.168.1.5')</code>	192.168.1.5/32

Any `cidr` value can be cast to `inet` implicitly or explicitly; therefore, the functions shown above as operating on `inet` also work on `cidr` values. (Where there are separate functions for `inet` and `cidr`, it is because the behavior should be different for the two cases.) Also, it is permitted to cast an `inet` value to `cidr`. When this is done, any bits to the right of the netmask are silently zeroed to create a valid `cidr` value. In addition, you can cast a text value to `inet` or `cidr` using normal casting syntax: for example, `inet(expression)` or `colname::cidr`.

Table 9-34 shows the functions available for use with the `macaddr` type. The function `trunc(macaddr)` returns a MAC address with the last 3 bytes set to zero. This can be used to associate the remaining prefix with a manufacturer.

**Table 9-34. `macaddr` Functions**

Function	Return Type	Description	Example	Result
<code>trunc(macaddr)</code>	<code>macaddr</code>	set last 3 bytes to zero	<code>trunc(macaddr '12:34:56:78:90:ab')</code>	12:34:56:00:00:00

The `macaddr` type also supports the standard relational operators (`>`, `<=`, etc.) for lexicographical ordering.

## 9.13. Text Search Functions and Operators

Table 9-35, Table 9-36 and Table 9-37 summarize the functions and operators that are provided for full text searching. See Chapter 12 for a detailed explanation of PostgreSQL's text search facility.

**Table 9-35. Text Search Operators**

Operator	Description	Example	Result
----------	-------------	---------	--------

Operator	Description	Example	Result
@@	tsvector matches tsquery ?	to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat')	t
@@@	same as @@, but see Section 12.9	to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat')	t
	concatenate tsvectors	'a':1 b:2':::tsvector    'c':1 d:2 b:3':::tsvector	'a':1 'b':2,5 'c':3 'd':4
&&	AND tsquerys together	'fat   rat':::tsquery && 'cat':::tsquery	( 'fat'   'rat' ) & 'cat'
	OR tsquerys together	'fat   rat':::tsquery    'cat':::tsquery	( 'fat'   'rat' )   'cat'
!!	negate a tsquery	!! 'cat':::tsquery	!'cat'
@>	tsquery contains another ?	'cat':::tsquery @> 'cat & rat':::tsquery	f
<@	tsquery is contained in ?	'cat':::tsquery <@ 'cat & rat':::tsquery	t

**Note:** The `tsquery` containment operators consider only the lexemes listed in the two queries, ignoring the combining operators.

In addition to the operators shown in the table, the ordinary B-tree comparison operators (`=`, `<`, etc) are defined for types `tsvector` and `tsquery`. These are not very useful for text searching but allow, for example, unique indexes to be built on columns of these types.

**Table 9-36. Text Search Functions**

Function	Return Type	Description	Example	Result	
to_tsvector([ config regconfig , ] document text)	tsvector	reduce document text to tsvector	to_tsvector('english', 'The Fat Rats')	'fat':2 'rat':3	

Function	Return Type	Description	Example	Result	
<code>length(tsvector)</code>	integer	number of lexemes in tsvector	<code>length('fat:2,4 3 cat:3 rat:5A':::tsvector)</code>		
<code>setweight(tsvector, "char")</code>	tsvector	assign weight to each element of tsvector	<code>setweight('fat:2,4A cat:3 rat:5B':::tsvector, 'A')</code>	<code>'fat':3A 'fat':2A,4A 'rat':5A</code>	
<code>strip(tsvector)</code>	tsvector	remove positions and weights from tsvector	<code>strip('fat:2,4 cat:3 rat:5A':::tsvector)</code>	<code>'cat' 'fat' 'rat'</code>	
<code>to_tsquery([ config regconfig , ] query text)</code>	tsquery	normalize words and convert to tsquery	<code>to_tsquery('english', 'The &amp; Fat &amp; Rats')</code>	<code>'fat', &amp; 'rat'</code>	
<code>plainto_tsquery( config regconfig , ] query text)</code>	tsquery	produce tsquery ignoring punctuation	<code>plainto_tsquery('english', 'The Fat Rats')</code>	<code>'fat' 'rat'</code>	
<code>numnode(tsquery)</code>	integer	number of lexemes plus operators in tsquery	<code>numnode('(fat &amp; rat)   cat':::tsquery)</code>	5	
<code>querytree(query tsquery)</code>	text	get indexable part of a tsquery	<code>querytree('foo &amp; ! bar':::tsquery)</code>	<code>'foo'</code>	
<code>ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])</code>	float4	rank document for query	<code>ts_rank(textsearch, query)</code>	0.1818	
<code>ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])</code>	float4	rank document for query using cover density	<code>ts_rank_cd('{0.1, 0.2, 0.4, 1.0}', textsearch, query)</code>	12.01317	

Function	Return Type	Description	Example	Result	
<code>ts_headline([ config regconfig, ] document text, query tsquery [, options text ])</code>	text	display a query match	<code>ts_headline('x y z', 'z':tsquery)</code>	<code>x y &lt;b&gt;z&lt;/b&gt;</code>	
<code>ts_rewrite(query tsquery, target tsquery, substitute tsquery)</code>	tsquery	replace target with substitute within query	<code>ts_rewrite('a &amp; b':tsquery, 'a':tsquery, 'foo bar':tsquery)</code>	<code>'b' &amp; ( 'foo'   'bar' )</code>	
<code>ts_rewrite(query tsquery, select text)</code>	tsquery	replace using targets and substitutes from a SELECT command	<code>SELECT ts_rewrite('a &amp; b':tsquery, 'SELECT t,s FROM aliases')</code>	<code>'b' &amp; ( 'foo'   'bar' )</code>	
<code>get_current_ts_config()</code>	config	get default text search configuration	<code>get_current_ts_config()</code>		
<code>tsvector_update_trigger()</code>	trigger	trigger function for automatic tsvector column update	<code>CREATE TRIGGER ... tsvector_update_trigger(tsvcol, 'pg_catalog.swedish', title, body)</code>		
<code>tsvector_update_trigger_column()</code>	trigger	trigger function for automatic tsvector column update	<code>CREATE TRIGGER ... tsvector_update_trigger_column(tsvcol, configcol, title, body)</code>		

**Note:** All the text search functions that accept an optional `regconfig` argument will use the configuration specified by `default_text_search_config` when that argument is omitted.

The functions in Table 9-37 are listed separately because they are not usually used in everyday text searching operations. They are helpful for development and debugging of new text search configurations.

**Table 9-37. Text Search Debugging Functions**

Function	Return Type	Description	Example	Result
----------	-------------	-------------	---------	--------

Function	Return Type	Description	Example	Result
ts_debug([ config regconfig, ] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])	set of record	test a configuration	ts_debug('english', 'The Brightest supernovae') ts_debug('english', 'The Brightest supernovae')	ts_debug('english', "Word, all ASCII", The, {english_stem}, en ...)
ts_lexize(dict regdictionary, token text)	text[]	test a dictionary	ts_lexize('english', 'stars')	ts_lexize('english', 'stars')
ts_parse(parser_name, text, document text, OUT tokid integer, OUT token text)	set of record	test a parser	ts_parse('default', 'foo - bar')	ts_parse('default', 'foo - bar') ...
ts_parse(parser_oid, oid, document text, OUT tokid integer, OUT token text)	set of record	test a parser	ts_parse(3722, 'foo - bar')	(1, foo) ...
ts_token_type(parser_name, text, OUT tokid integer, OUT alias text, OUT description text)	set of record	get token types defined by parser	ts_token_type('default', 'foo - bar')	ts_token_type('default', 'foo - bar') ...
ts_token_type(parser_oid, oid, OUT tokid integer, OUT alias text, OUT description text)	set of record	get token types defined by parser	ts_token_type(3722, 'foo - bar')	ts_token_type(3722, 'foo - bar') ...

Function	Return Type	Description	Example	Result
<code>ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndoc integer, OUT nentry integer)</code>	setof record	get statistics of a tsvector column	<code>ts_stat('SELECT vector from apod')</code>	<code>(foo,10,15)</code> ...

## 9.14. XML Functions

The functions and function-like expressions described in this section operate on values of type `xml`. Check Section 8.13 for information about the `xml` type. The function-like expressions `xmlparse` and `xmlserialize` for converting to and from type `xml` are not repeated here. Use of many of these functions requires the installation to have been built with `configure --with-libxml`.

### 9.14.1. Producing XML Content

A set of functions and function-like expressions are available for producing XML content from SQL data. As such, they are particularly suitable for formatting query results into XML documents for processing in client applications.

#### 9.14.1.1. `xmlcomment`

`xmlcomment(text)`

The function `xmlcomment` creates an XML value containing an XML comment with the specified text as content. The text cannot contain `--` or end with a `-` so that the resulting construct is a valid XML comment. If the argument is null, the result is null.

Example:

```
SELECT xmlcomment('hello');
```

```
xmlcomment
-----
<!--hello-->
```

#### 9.14.1.2. `xmlconcat`

`xmlconcat(xml[, ...])`

The function `xmlconcat` concatenates a list of individual XML values to create a single value containing an XML content fragment. Null values are omitted; the result is only null if there are no nonnull arguments.

Example:

```
SELECT xmlconcat ('<abc/>', '<bar>foo</bar>');
```

```
      xmlconcat
-----
<abc/><bar>foo</bar>
```

XML declarations, if present, are combined as follows. If all argument values have the same XML version declaration, that version is used in the result, else no version is used. If all argument values have the standalone declaration value “yes”, then that value is used in the result. If all argument values have a standalone declaration value and at least one is “no”, then that is used in the result. Else the result will have no standalone declaration. If the result is determined to require a standalone declaration but no version declaration, a version declaration with version 1.0 will be used because XML requires an XML declaration to contain a version declaration. Encoding declarations are ignored and removed in all cases.

Example:

```
SELECT xmlconcat ('<?xml version="1.1"?><foo/>', '<?xml version="1.1" standalone="no"?><bar/
```

```
      xmlconcat
-----
<?xml version="1.1"?><foo/><bar/>
```

### 9.14.1.3. xmlelement

```
xmlelement(name name [, xmlattributes(value [AS attname] [, ... ])] [, content, ...])
```

The `xmlelement` expression produces an XML element with the given name, attributes, and content.

Examples:

```
SELECT xmlelement(name foo);
```

```
      xmlelement
-----
<foo/>
```

```
SELECT xmlelement(name foo, xmlattributes('xyz' as bar));
```

```
      xmlelement
-----
<foo bar="xyz"/>
```

```
SELECT xmlelement(name foo, xmlattributes(current_date as bar), 'cont', 'ent');
```

```

xmlelement
-----
<foo bar="2007-01-26">content</foo>

```

Element and attribute names that are not valid XML names are escaped by replacing the offending characters by the sequence `_xHHHH_`, where `HHHH` is the character's Unicode codepoint in hexadecimal notation. For example:

```

SELECT xmlelement(name "foo$bar", xmlattributes('xyz' as "a&b"));

xmlelement
-----
<foo_x0024_bar a_x0026_b="xyz"/>

```

An explicit attribute name need not be specified if the attribute value is a column reference, in which case the column's name will be used as attribute name by default. In any other case, the attribute must be given an explicit name. So this example is valid:

```

CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;

```

But these are not:

```

SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;

```

Element content, if specified, will be formatted according to data type. If the content is itself of type `xml`, complex XML documents can be constructed. For example:

```

SELECT xmlelement(name foo, xmlattributes('xyz' as bar),
                  xmlelement(name abc),
                  xmlcomment('test'),
                  xmlelement(name xyz));

xmlelement
-----
<foo bar="xyz"><abc/><!--test--><xyz/></foo>

```

Content of other types will be formatted into valid XML character data. This means in particular that the characters `<`, `>`, and `&` will be converted to entities. Binary data (data type `bytea`) will be represented in base64 or hex encoding, depending on the setting of the configuration parameter `xmlbinary`. The particular behavior for individual data types is expected to evolve in order to align the SQL and PostgreSQL data types with the XML Schema specification, at which point a more precise description will appear.

**9.14.1.4. xmlforest**

```
xmlforest (content [AS name] [, ...])
```

The `xmlforest` expression produces an XML forest (sequence) of elements using the given names and content.

Examples:

```
SELECT xmlforest('abc' AS foo, 123 AS bar);
```

```
          xmlforest
-----
<foo>abc</foo><bar>123</bar>
```

```
SELECT xmlforest(table_name, column_name) FROM information_schema.columns WHERE table_schem
```

```
          xmlforest
-----
<table_name>pg_authid</table_name><column_name>rolname</column_name>
<table_name>pg_authid</table_name><column_name>rolsuper</column_name>
...
```

As seen in the second example, the element name can be omitted if the content value is a column reference, in which case the column name is used by default. Otherwise, a name must be specified.

Element names that are not valid XML names are escaped as shown for `xmlelement` above. Similarly, content data is escaped to make valid XML content, unless it is already of type `xml`.

Note that XML forests are not valid XML documents if they consist of more than one element. So it might be useful to wrap `xmlforest` expressions in `xmlelement`.

**9.14.1.5. xmlpi**

```
xmlpi(name target [, content])
```

The `xmlpi` expression creates an XML processing instruction. The content, if present, must not contain the character sequence `?>`.

Example:

```
SELECT xmlpi(name php, 'echo "hello world";');
```

```
          xmlpi
-----
<?php echo "hello world";?>
```

**9.14.1.6. xmlroot**

```
xmlroot(xml, version text|no value [, standalone yes|no|no value])
```

The `xmlroot` expression alters the properties of the root node of an XML value. If a version is specified, this replaces the value in the version declaration, if a standalone value is specified, this replaces the value in the standalone declaration.

```
SELECT xmlroot(xmlparse(document '<?xml version="1.1"?><content>abc</content>'), version '1.0', standalone 'yes')
xmlroot
-----
<?xml version="1.0" standalone="yes"?>
<content>abc</content>
```

**9.14.1.7. XML Predicates**

```
xml IS DOCUMENT
```

The expression `IS DOCUMENT` returns true if the argument XML value is a proper XML document, false if it is not (that is, it is a content fragment), or null if the argument is null. See Section 8.13 about the difference between documents and content fragments.

**9.14.2. Processing XML**

To process values of data type `xml`, PostgreSQL offers the function `xpath`, which evaluates XPath 1.0 expressions.

```
xpath(xpath, xml[, nsarray])
```

The function `xpath` evaluates the XPath expression `xpath` against the XML value `xml`. It returns an array of XML values corresponding to the node set produced by the XPath expression.

The third argument of the function is an array of namespace mappings. This array should be a two-dimensional array with the length of the second axis being equal to 2 (i.e., it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name, the second the namespace URI.

Example:

```
SELECT xpath('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>', ARRAY[ARRAY[
xpath
-----
{test}
(1 row)
```

### 9.14.3. Mapping Tables to XML

The following functions map the contents of relational tables to XML values. They can be thought of as XML export functionality.

```
table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)
```

The return type of each function is `xml`.

`table_to_xml` maps the content of the named table, passed as parameter `tbl`. The `regclass` type accepts strings identifying tables using the usual notation, including optional schema qualifications and double quotes. `query_to_xml` executes the query whose text is passed as parameter `query` and maps the result set. `cursor_to_xml` fetches the indicated number of rows from the cursor specified by the parameter `cursor`. This variant is recommendable if large tables have to be mapped, because the result value is built up in memory by each function.

If `tableforest` is false, then the resulting XML document looks like this:

```
<tablename>
  <row>
    <columnname1>data</columnname1>
    <columnname2>data</columnname2>
  </row>

  <row>
    ...
  </row>

  ...
</tablename>
```

If `tableforest` is true, the result is an XML content fragment that looks like this:

```
<tablename>
  <columnname1>data</columnname1>
  <columnname2>data</columnname2>
</tablename>

<tablename>
  ...
</tablename>

...
```

If no table name is available, that is, when mapping a query or a cursor, the string `table` is used in the first format, `row` in the second format.

The choice between these formats is up to the user. The first format is a proper XML document, which will be important in many applications. The second format tends to be more useful in the `cursor_to_xml` function if the result values are to be reassembled into one document later on. The functions for producing XML content discussed above, in particular `xmlelement`, can be used to alter the results to taste.

The data values are mapped in the same way as described for the function `xmlelement` above.

The parameter `nulls` determines whether null values should be included in the output. If true, null values in columns are represented as

```
<columnname xsi:nil="true"/>
```

where `xsi` is the XML namespace prefix for XML Schema Instance. An appropriate namespace declaration will be added to the result value. If false, columns containing null values are simply omitted from the output.

The parameter `targetns` specifies the desired XML namespace of the result. If no particular namespace is wanted, an empty string should be passed.

The following functions return XML Schema documents describing the mappings made by the data mappings produced by the corresponding functions above.

```
table_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)
```

It is essential that the same parameters are passed in order to obtain matching XML data mappings and XML Schema documents.

The following functions produce XML data mappings and the corresponding XML Schema in one document (or forest), linked together. They can be useful where self-contained and self-describing results are wanted.

```
table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)
query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)
```

In addition, the following functions are available to produce analogous mappings of entire schemas or the entire current database.

```
schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)
schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)

database_to_xml(nulls boolean, tableforest boolean, targetns text)
database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)
database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)
```

Note that these potentially produce a lot of data, which needs to be built up in memory. When requesting content mappings of large schemas or databases, it may be worthwhile to consider mapping the tables separately instead, possibly even through a cursor.

The result of a schema content mapping looks like this:

```
<schemaname>
```

```

table1-mapping

table2-mapping

...

</schemaname>

```

where the format of a table mapping depends on the `tableforest` parameter as explained above.

The result of a database content mapping looks like this:

```

<dbname>

<schemaname>
  ...
</schemaname>

<schema2name>
  ...
</schema2name>

...

</dbname>

```

where the schema mapping is as above.

As an example for using the output produced by these functions, Figure 9-1 shows an XSLT stylesheet that converts the output of `table_to_xml_and_xmlschema` to an HTML document containing a tabular rendition of the table data. In a similar manner, the result data of these functions can be converted into other XML-based formats.

**Figure 9-1. XSLT stylesheet for converting SQL/XML output to HTML**

```

<?xml version="1.0"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.w3.org/1999/xhtml"
>

  <xsl:output method="xml"
    doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd"
    doctype-public="-//W3C/DTD XHTML 1.0 Strict//EN"
    indent="yes"/>

  <xsl:template match="/*">
    <xsl:variable name="schema" select="//xsd:schema"/>
    <xsl:variable name="tabletypename"
      select="$schema/xsd:element[@name=name(current())]/@type"/>
    <xsl:variable name="rowtypename"
      select="$schema/xsd:complexType[@name=$tabletypename]/xsd:sequence/xsd:el

```

```

<html>
  <head>
    <title><xsl:value-of select="name(current())"/></title>
  </head>
  <body>
    <table>
      <tr>
        <xsl:for-each select="$schema/xsd:complexType[@name=$rowtypename]/xsd:sequence/
          <th><xsl:value-of select="."/></th>
        </xsl:for-each>
      </tr>

      <xsl:for-each select="row">
        <tr>
          <xsl:for-each select="*">
            <td><xsl:value-of select="."/></td>
          </xsl:for-each>
        </tr>
      </xsl:for-each>
    </table>
  </body>
</html>
</xsl:template>

</xsl:stylesheet>

```

## 9.15. Sequence Manipulation Functions

This section describes PostgreSQL's functions for operating on *sequence objects*. Sequence objects (also called sequence generators or just sequences) are special single-row tables created with *CREATE SEQUENCE*. A sequence object is usually used to generate unique identifiers for rows of a table. The sequence functions, listed in Table 9-38, provide simple, multiuser-safe methods for obtaining successive sequence values from sequence objects.

**Table 9-38. Sequence Functions**

Function	Return Type	Description
<code>currval (regclass)</code>	<code>bigint</code>	Return value most recently obtained with <code>nextval</code> for specified sequence
<code>lastval ()</code>	<code>bigint</code>	Return value most recently obtained with <code>nextval</code> for any sequence
<code>nextval (regclass)</code>	<code>bigint</code>	Advance sequence and return new value

Function	Return Type	Description
<code>setval(regclass, bigint)</code>	<code>bigint</code>	Set sequence's current value
<code>setval(regclass, bigint, boolean)</code>	<code>bigint</code>	Set sequence's current value and <code>is_called</code> flag

The sequence to be operated on by a sequence-function call is specified by a `regclass` argument, which is just the OID of the sequence in the `pg_class` system catalog. You do not have to look up the OID by hand, however, since the `regclass` data type's input converter will do the work for you. Just write the sequence name enclosed in single quotes, so that it looks like a literal constant. To achieve some compatibility with the handling of ordinary SQL names, the string will be converted to lowercase unless it contains double quotes around the sequence name. Thus:

```
nextval('foo')           operates on sequence foo
nextval('FOO')           operates on sequence foo
nextval('"Foo"')         operates on sequence Foo
```

The sequence name can be schema-qualified if necessary:

```
nextval('myschema.foo')   operates on myschema.foo
nextval('"myschema".foo') same as above
nextval('foo')            searches search path for foo
```

See Section 8.16 for more information about `regclass`.

**Note:** Before PostgreSQL 8.1, the arguments of the sequence functions were of type `text`, not `regclass`, and the above-described conversion from a text string to an OID value would happen at run time during each call. For backwards compatibility, this facility still exists, but internally it is now handled as an implicit coercion from `text` to `regclass` before the function is invoked.

When you write the argument of a sequence function as an unadorned literal string, it becomes a constant of type `regclass`. Since this is really just an OID, it will track the originally identified sequence despite later renaming, schema reassignment, etc. This “early binding” behavior is usually desirable for sequence references in column defaults and views. But sometimes you will want “late binding” where the sequence reference is resolved at run time. To get late-binding behavior, force the constant to be stored as a `text` constant instead of `regclass`:

```
nextval('foo'::text)      foo is looked up at runtime
```

Note that late binding was the only behavior supported in PostgreSQL releases before 8.1, so you might need to do this to preserve the semantics of old applications.

Of course, the argument of a sequence function can be an expression as well as a constant. If it is a text expression then the implicit coercion will result in a run-time lookup.

The available sequence functions are:

`nextval`

Advance the sequence object to its next value and return that value. This is done atomically: even if multiple sessions execute `nextval` concurrently, each will safely receive a distinct sequence value.

`currval`

Return the value most recently obtained by `nextval` for this sequence in the current session. (An error is reported if `nextval` has never been called for this sequence in this session.) Notice that because this is returning a session-local value, it gives a predictable answer whether or not other sessions have executed `nextval` since the current session did.

`lastval`

Return the value most recently returned by `nextval` in the current session. This function is identical to `currval`, except that instead of taking the sequence name as an argument it fetches the value of the last sequence that `nextval` was used on in the current session. It is an error to call `lastval` if `nextval` has not yet been called in the current session.

`setval`

Reset the sequence object's counter value. The two-parameter form sets the sequence's `last_value` field to the specified value and sets its `is_called` field to `true`, meaning that the next `nextval` will advance the sequence before returning a value. The value reported by `currval` is also set to the specified value. In the three-parameter form, `is_called` can be set either `true` or `false`. `true` has the same effect as the two-parameter form. If it's set to `false`, the next `nextval` will return exactly the specified value, and sequence advancement commences with the following `nextval`. Furthermore, the value reported by `currval` is not changed in this case (this is a change from pre-8.3 behavior). For example,

```
SELECT setval('foo', 42);           Next nextval will return 43
SELECT setval('foo', 42, true);     Same as above
SELECT setval('foo', 42, false);    Next nextval will return 42
```

The result returned by `setval` is just the value of its second argument.

If a sequence object has been created with default parameters, `nextval` calls on it will return successive values beginning with 1. Other behaviors can be obtained by using special parameters in the `CREATE SEQUENCE` command; see its command reference page for more information.

**Important:** To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value has been fetched it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions might leave unused “holes” in the sequence of assigned values. `setval` operations are never rolled back, either.

## 9.16. Conditional Expressions

This section describes the SQL-compliant conditional expressions available in PostgreSQL.

**Tip:** If your needs go beyond the capabilities of these conditional expressions you might want to consider writing a stored procedure in a more expressive programming language.

### 9.16.1. CASE

The SQL `CASE` expression is a generic conditional expression, similar to if/else statements in other languages:

```
CASE WHEN condition THEN result
      [WHEN ...]
      [ELSE result]
END
```

`CASE` clauses can be used wherever an expression is valid. *condition* is an expression that returns a boolean result. If the result is true then the value of the `CASE` expression is the *result* that follows the condition. If the result is false any subsequent `WHEN` clauses are searched in the same manner. If no `WHEN` *condition* is true then the value of the case expression is the *result* in the `ELSE` clause. If the `ELSE` clause is omitted and no condition matches, the result is null.

An example:

```
SELECT * FROM test;
```

```
a
---
1
2
3
```

```
SELECT a,
       CASE WHEN a=1 THEN 'one'
            WHEN a=2 THEN 'two'
            ELSE 'other'
       END
FROM test;
```

```
a | case
---+-----
1 | one
2 | two
3 | other
```

The data types of all the *result* expressions must be convertible to a single output type. See Section 10.5 for more detail.

The following “simple” `CASE` expression is a specialized variant of the general form above:

```
CASE expression
     WHEN value THEN result
     [WHEN ...]
     [ELSE result]
END
```

The *expression* is computed and compared to all the *value* specifications in the `WHEN` clauses until one is found that is equal. If no match is found, the *result* in the `ELSE` clause (or a null value) is returned. This is similar to the `switch` statement in C.

The example above can be written using the simple `CASE` syntax:

```
SELECT a,
       CASE a WHEN 1 THEN 'one'
              WHEN 2 THEN 'two'
              ELSE 'other'
       END
FROM test;
```

```
a | case
---+-----
1 | one
2 | two
3 | other
```

A `CASE` expression does not evaluate any subexpressions that are not needed to determine the result. For example, this is a possible way of avoiding a division-by-zero failure:

```
SELECT ... WHERE CASE WHEN x <> 0 THEN y/x > 1.5 ELSE false END;
```

### 9.16.2. COALESCE

```
COALESCE(value [, ...])
```

The `COALESCE` function returns the first of its arguments that is not null. Null is returned only if all arguments are null. It is often used to substitute a default value for null values when data is retrieved for display, for example:

```
SELECT COALESCE(description, short_description, '(none)') ...
```

Like a `CASE` expression, `COALESCE` will not evaluate arguments that are not needed to determine the result; that is, arguments to the right of the first non-null argument are not evaluated. This SQL-standard function provides capabilities similar to `NVL` and `IFNULL`, which are used in some other database systems.

### 9.16.3. NULLIF

```
NULLIF(value1, value2)
```

The `NULLIF` function returns a null value if *value1* and *value2* are equal; otherwise it returns *value1*. This can be used to perform the inverse operation of the `COALESCE` example given above:

```
SELECT NULLIF(value, '(none)') ...
```

If *value1* is (none), return a null, otherwise return *value1*.

## 9.16.4. GREATEST and LEAST

```
GREATEST(value [, ...])
```

```
LEAST(value [, ...])
```

The `GREATEST` and `LEAST` functions select the largest or smallest value from a list of any number of expressions. The expressions must all be convertible to a common data type, which will be the type of the result (see Section 10.5 for details). NULL values in the list are ignored. The result will be NULL only if all the expressions evaluate to NULL.

Note that `GREATEST` and `LEAST` are not in the SQL standard, but are a common extension. Some other databases make them return NULL if any argument is NULL, rather than only when all are NULL.

## 9.17. Array Functions and Operators

Table 9-39 shows the operators available for array types.

**Table 9-39. array Operators**

Operator	Description	Example	Result
=	equal	<code>ARRAY[1,1,2,1,3,1]::int[] = ARRAY[1,2,3]</code>	t
<>	not equal	<code>ARRAY[1,2,3] &lt;&gt; ARRAY[1,2,4]</code>	t
<	less than	<code>ARRAY[1,2,3] &lt; ARRAY[1,2,4]</code>	t
>	greater than	<code>ARRAY[1,4,3] &gt; ARRAY[1,2,4]</code>	t
<=	less than or equal	<code>ARRAY[1,2,3] &lt;= ARRAY[1,2,3]</code>	t
>=	greater than or equal	<code>ARRAY[1,4,3] &gt;= ARRAY[1,4,3]</code>	t
@>	contains	<code>ARRAY[1,4,3] @&gt; ARRAY[3,1]</code>	t
<@	is contained by	<code>ARRAY[2,7] &lt;@ ARRAY[1,7,4,2,6]</code>	t

Operator	Description	Example	Result
&&	overlap (have elements in common)	ARRAY[1,4,3] && ARRAY[2,1]	t
	array-to-array concatenation	ARRAY[1,2,3]    ARRAY[4,5,6]	{1,2,3,4,5,6}
	array-to-array concatenation	ARRAY[1,2,3]    ARRAY[[4,5,6],[7,8,9]]	{{1,2,3},{4,5,6},{7,8,9}}
	element-to-array concatenation	3    ARRAY[4,5,6]	{3,4,5,6}
	array-to-element concatenation	ARRAY[4,5,6]    7	{4,5,6,7}

Array comparisons compare the array contents element-by-element, using the default B-Tree comparison function for the element data type. In multidimensional arrays the elements are visited in row-major order (last subscript varies most rapidly). If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order. (This is a change from versions of PostgreSQL prior to 8.2: older versions would claim that two arrays with the same contents were equal, even if the number of dimensions or subscript ranges were different.)

See Section 8.14 for more details about array operator behavior.

Table 9-40 shows the functions available for use with array types. See Section 8.14 for more discussion and examples of the use of these functions.

**Table 9-40. array Functions**

Function	Return Type	Description	Example	Result
array_append(anyarray, anyelement)	anyarray	append an element to the end of an array	array_append(ARRAY[1,2], 3)	{1,2,3}
array_cat(anyarray, anyarray)	anyarray	concatenate two arrays	array_cat(ARRAY[1,2,3], ARRAY[4,5])	{1,2,3,4,5}
array_dims(anyarray)	text	returns a text representation of array's dimensions	array_dims(ARRAY[[1,2,3][4,5,6]])	{[1:3][2:3]}
array_lower(anyarray, int)	int	returns lower bound of the requested array dimension	array_lower(' [0:2]={1,2,3}'::int[], 1)	0
array_prepend(anyelement, anyarray)	anyarray	append an element to the beginning of an array	array_prepend(1, ARRAY[2,3])	{1,2,3}
array_to_string(anyarray, text)	text	concatenates array elements using provided delimiter	array_to_string(ARRAY[1,2,3], '~')	{1~2~3}

Function	Return Type	Description	Example	Result
<code>array_upper (anyarray, int)</code>	int	returns upper bound of the requested array dimension	<code>array_upper (ARRAY [1, 2, 3, 4], 1)</code>	
<code>string_to_array (text, text)</code>	text []	splits string into array elements using provided delimiter	<code>string_to_array ('xxx~yy~zz', '~')</code>	

## 9.18. Aggregate Functions

*Aggregate functions* compute a single result value from a set of input values. The built-in aggregate functions are listed in Table 9-41 and Table 9-42. The special syntax considerations for aggregate functions are explained in Section 4.2.7. Consult Section 2.7 for additional introductory information.

**Table 9-41. General-Purpose Aggregate Functions**

Function	Argument Type	Return Type	Description
<code>avg (expression)</code>	smallint, int, bigint, real, double precision, numeric, or interval	numeric for any integer type argument, double precision for a floating-point argument, otherwise the same as the argument data type	the average (arithmetic mean) of all input values
<code>bit_and (expression)</code>	smallint, int, bigint, or bit	same as argument data type	the bitwise AND of all non-null input values, or null if none
<code>bit_or (expression)</code>	smallint, int, bigint, or bit	same as argument data type	the bitwise OR of all non-null input values, or null if none
<code>bool_and (expression)</code>	bool	bool	true if all input values are true, otherwise false
<code>bool_or (expression)</code>	bool	bool	true if at least one input value is true, otherwise false
<code>count (*)</code>		bigint	number of input rows
<code>count (expression)</code>	any	bigint	number of input rows for which the value of <i>expression</i> is not null

Function	Argument Type	Return Type	Description
<code>every(expression)</code>	<code>bool</code>	<code>bool</code>	equivalent to <code>bool_and</code>
<code>max(expression)</code>	any array, numeric, string, or date/time type	same as argument type	maximum value of <i>expression</i> across all input values
<code>min(expression)</code>	any array, numeric, string, or date/time type	same as argument type	minimum value of <i>expression</i> across all input values
<code>sum(expression)</code>	smallint, int, bigint, real, double precision, numeric, or interval	bigint for smallint or int arguments, numeric for bigint arguments, double precision for floating-point arguments, otherwise the same as the argument data type	sum of <i>expression</i> across all input values

It should be noted that except for `count`, these functions return a null value when no rows are selected. In particular, `sum` of no rows returns null, not zero as one might expect. The `coalesce` function can be used to substitute zero for null when necessary.

**Note:** Boolean aggregates `bool_and` and `bool_or` correspond to standard SQL aggregates `every` and `any` or `some`. As for `any` and `some`, it seems that there is an ambiguity built into the standard syntax:

```
SELECT b1 = ANY((SELECT b2 FROM t2 ...)) FROM t1 ...;
```

Here `ANY` can be considered both as leading to a subquery or as an aggregate if the select expression returns 1 row. Thus the standard name cannot be given to these aggregates.

**Note:** Users accustomed to working with other SQL database management systems might be surprised by the performance of the `count` aggregate when it is applied to the entire table. A query like:

```
SELECT count(*) FROM sometable;
```

will be executed by PostgreSQL using a sequential scan of the entire table.

Table 9-42 shows aggregate functions typically used in statistical analysis. (These are separated out merely to avoid cluttering the listing of more-commonly-used aggregates.) Where the description mentions *N*, it means the number of input rows for which all the input expressions are non-null. In all cases, null is returned if the computation is meaningless, for example when *N* is zero.

**Table 9-42. Aggregate Functions for Statistics**

Function	Argument Type	Return Type	Description
<code>corr(Y, X)</code>	double precision	double precision	correlation coefficient
<code>covar_pop(Y, X)</code>	double precision	double precision	population covariance
<code>covar_samp(Y, X)</code>	double precision	double precision	sample covariance
<code>regr_avgx(Y, X)</code>	double precision	double precision	average of the independent variable ( $\text{sum}(X) / N$ )
<code>regr_avgy(Y, X)</code>	double precision	double precision	average of the dependent variable ( $\text{sum}(Y) / N$ )
<code>regr_count(Y, X)</code>	double precision	bigint	number of input rows in which both expressions are nonnull
<code>regr_intercept(Y, X)</code>	double precision	double precision	y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs
<code>regr_r2(Y, X)</code>	double precision	double precision	square of the correlation coefficient
<code>regr_slope(Y, X)</code>	double precision	double precision	slope of the least-squares-fit linear equation determined by the (X, Y) pairs
<code>regr_sxx(Y, X)</code>	double precision	double precision	$\text{sum}(X^2) - \text{sum}(X)^2 / N$ (“sum of squares” of the independent variable)
<code>regr_sxy(Y, X)</code>	double precision	double precision	$\text{sum}(X * Y) - \text{sum}(X) * \text{sum}(Y) / N$ (“sum of products” of independent times dependent variable)
<code>regr_syy(Y, X)</code>	double precision	double precision	$\text{sum}(Y^2) - \text{sum}(Y)^2 / N$ (“sum of squares” of the dependent variable)
<code>stddev(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	historical alias for <code>stddev_samp</code>
<code>stddev_pop(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	population standard deviation of the input values

Function	Argument Type	Return Type	Description
<code>stddev_samp(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	sample standard deviation of the input values
<code>variance(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	historical alias for <code>var_samp</code>
<code>var_pop(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	population variance of the input values (square of the population standard deviation)
<code>var_samp(expression)</code>	smallint, int, bigint, real, double precision, or numeric	double precision for floating-point arguments, otherwise numeric	sample variance of the input values (square of the sample standard deviation)

## 9.19. Subquery Expressions

This section describes the SQL-compliant subquery expressions available in PostgreSQL. All of the expression forms documented in this section return Boolean (true/false) results.

### 9.19.1. EXISTS

`EXISTS (subquery)`

The argument of `EXISTS` is an arbitrary `SELECT` statement, or *subquery*. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of `EXISTS` is “true”; if the subquery returns no rows, the result of `EXISTS` is “false”.

The subquery can refer to variables from the surrounding query, which will act as constants during any one evaluation of the subquery.

The subquery will generally only be executed far enough to determine whether at least one row is returned, not all the way to completion. It is unwise to write a subquery that has any side effects (such as calling sequence functions); whether the side effects occur or not might be difficult to predict.

Since the result depends only on whether any rows are returned, and not on the contents of those rows, the output list of the subquery is normally uninteresting. A common coding convention is to write all `EXISTS` tests in the form `EXISTS(SELECT 1 WHERE ...)`. There are exceptions to this rule however, such as subqueries that use `INTERSECT`.

This simple example is like an inner join on `col2`, but it produces at most one output row for each `tab1` row, even if there are multiple matching `tab2` rows:

```
SELECT col1 FROM tab1
```

```
WHERE EXISTS(SELECT 1 FROM tab2 WHERE col2 = tab1.col2);
```

### 9.19.2. IN

```
expression IN (subquery)
```

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of `IN` is “true” if any equal subquery row is found. The result is “false” if no equal row is found (including the special case where the subquery returns no rows).

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand row yields null, the result of the `IN` construct will be null, not false. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As with `EXISTS`, it’s unwise to assume that the subquery will be evaluated completely.

```
row_constructor IN (subquery)
```

The left-hand side of this form of `IN` is a row constructor, as described in Section 4.2.11. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result. The result of `IN` is “true” if any equal subquery row is found. The result is “false” if no equal row is found (including the special case where the subquery returns no rows).

As usual, null values in the rows are combined per the normal rules of SQL Boolean expressions. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of that row comparison is unknown (null). If all the per-row results are either unequal or null, with at least one null, then the result of `IN` is null.

### 9.19.3. NOT IN

```
expression NOT IN (subquery)
```

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of `NOT IN` is “true” if only unequal subquery rows are found (including the special case where the subquery returns no rows). The result is “false” if any equal row is found.

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand row yields null, the result of the `NOT IN` construct will be null, not true. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As with `EXISTS`, it’s unwise to assume that the subquery will be evaluated completely.

```
row_constructor NOT IN (subquery)
```

The left-hand side of this form of `NOT IN` is a row constructor, as described in Section 4.2.11. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result. The result of `NOT IN` is “true” if only unequal subquery rows are found (including the special case where the subquery returns no rows). The result is “false” if any equal row is found.

As usual, null values in the rows are combined per the normal rules of SQL Boolean expressions. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of that row comparison is unknown (null). If all the per-row results are either unequal or null, with at least one null, then the result of `NOT IN` is null.

### 9.19.4. ANY/SOME

```
expression operator ANY (subquery)
expression operator SOME (subquery)
```

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given *operator*, which must yield a Boolean result. The result of `ANY` is “true” if any true result is obtained. The result is “false” if no true result is found (including the special case where the subquery returns no rows).

`SOME` is a synonym for `ANY`. `IN` is equivalent to `= ANY`.

Note that if there are no successes and at least one right-hand row yields null for the operator’s result, the result of the `ANY` construct will be null, not false. This is in accordance with SQL’s normal rules for Boolean combinations of null values.

As with `EXISTS`, it’s unwise to assume that the subquery will be evaluated completely.

```
row_constructor operator ANY (subquery)
row_constructor operator SOME (subquery)
```

The left-hand side of this form of `ANY` is a row constructor, as described in Section 4.2.11. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result, using the given *operator*. The result of `ANY` is “true” if the comparison returns true for any subquery row. The result is “false” if the comparison returns false for every subquery row (including the special case where the subquery returns no rows). The result is `NULL` if the comparison does not return true for any row, and it returns `NULL` for at least one row.

See Section 9.20.5 for details about the meaning of a row-wise comparison.

### 9.19.5. ALL

```
expression operator ALL (subquery)
```

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given *operator*, which must yield a Boolean result. The result of `ALL` is “true” if all rows yield true (including the special

case where the subquery returns no rows). The result is “false” if any false result is found. The result is NULL if the comparison does not return false for any row, and it returns NULL for at least one row.

NOT IN is equivalent to <> ALL.

As with EXISTS, it’s unwise to assume that the subquery will be evaluated completely.

```
row_constructor operator ALL (subquery)
```

The left-hand side of this form of ALL is a row constructor, as described in Section 4.2.11. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. The left-hand expressions are evaluated and compared row-wise to each row of the subquery result, using the given *operator*. The result of ALL is “true” if the comparison returns true for all subquery rows (including the special case where the subquery returns no rows). The result is “false” if the comparison returns false for any subquery row. The result is NULL if the comparison does not return false for any subquery row, and it returns NULL for at least one row.

See Section 9.20.5 for details about the meaning of a row-wise comparison.

### 9.19.6. Row-wise Comparison

```
row_constructor operator (subquery)
```

The left-hand side is a row constructor, as described in Section 4.2.11. The right-hand side is a parenthesized subquery, which must return exactly as many columns as there are expressions in the left-hand row. Furthermore, the subquery cannot return more than one row. (If it returns zero rows, the result is taken to be null.) The left-hand side is evaluated and compared row-wise to the single subquery result row.

See Section 9.20.5 for details about the meaning of a row-wise comparison.

## 9.20. Row and Array Comparisons

This section describes several specialized constructs for making multiple comparisons between groups of values. These forms are syntactically related to the subquery forms of the previous section, but do not involve subqueries. The forms involving array subexpressions are PostgreSQL extensions; the rest are SQL-compliant. All of the expression forms documented in this section return Boolean (true/false) results.

### 9.20.1. IN

```
expression IN (value [, ...])
```

The right-hand side is a parenthesized list of scalar expressions. The result is “true” if the left-hand expression’s result is equal to any of the right-hand expressions. This is a shorthand notation for

```
expression = value1
OR
expression = value2
OR
```

...

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand expression yields null, the result of the `IN` construct will be null, not false. This is in accordance with SQL's normal rules for Boolean combinations of null values.

### 9.20.2. NOT IN

```
expression NOT IN (value [, ...])
```

The right-hand side is a parenthesized list of scalar expressions. The result is “true” if the left-hand expression's result is unequal to all of the right-hand expressions. This is a shorthand notation for

```
expression <> value1
AND
expression <> value2
AND
...
```

Note that if the left-hand expression yields null, or if there are no equal right-hand values and at least one right-hand expression yields null, the result of the `NOT IN` construct will be null, not true as one might naively expect. This is in accordance with SQL's normal rules for Boolean combinations of null values.

**Tip:** `x NOT IN y` is equivalent to `NOT (x IN y)` in all cases. However, null values are much more likely to trip up the novice when working with `NOT IN` than when working with `IN`. It's best to express your condition positively if possible.

### 9.20.3. ANY/SOME (array)

```
expression operator ANY (array expression)
expression operator SOME (array expression)
```

The right-hand side is a parenthesized expression, which must yield an array value. The left-hand expression is evaluated and compared to each element of the array using the given *operator*, which must yield a Boolean result. The result of `ANY` is “true” if any true result is obtained. The result is “false” if no true result is found (including the special case where the array has zero elements).

If the array expression yields a null array, the result of `ANY` will be null. If the left-hand expression yields null, the result of `ANY` is ordinarily null (though a non-strict comparison operator could possibly yield a different result). Also, if the right-hand array contains any null elements and no true comparison result is obtained, the result of `ANY` will be null, not false (again, assuming a strict comparison operator). This is in accordance with SQL's normal rules for Boolean combinations of null values.

`SOME` is a synonym for `ANY`.

### 9.20.4. ALL (array)

*expression operator ALL (array expression)*

The right-hand side is a parenthesized expression, which must yield an array value. The left-hand expression is evaluated and compared to each element of the array using the given *operator*, which must yield a Boolean result. The result of ALL is “true” if all comparisons yield true (including the special case where the array has zero elements). The result is “false” if any false result is found.

If the array expression yields a null array, the result of ALL will be null. If the left-hand expression yields null, the result of ALL is ordinarily null (though a non-strict comparison operator could possibly yield a different result). Also, if the right-hand array contains any null elements and no false comparison result is obtained, the result of ALL will be null, not true (again, assuming a strict comparison operator). This is in accordance with SQL’s normal rules for Boolean combinations of null values.

### 9.20.5. Row-wise Comparison

*row\_constructor operator row\_constructor*

Each side is a row constructor, as described in Section 4.2.11. The two row values must have the same number of fields. Each side is evaluated and they are compared row-wise. Row comparisons are allowed when the *operator* is =, <>, <, <=, > or >=, or has semantics similar to one of these. (To be specific, an operator can be a row comparison operator if it is a member of a B-Tree operator class, or is the negator of the = member of a B-Tree operator class.)

The = and <> cases work slightly differently from the others. Two rows are considered equal if all their corresponding members are non-null and equal; the rows are unequal if any corresponding members are non-null and unequal; otherwise the result of the row comparison is unknown (null).

For the <, <=, > and >= cases, the row elements are compared left-to-right, stopping as soon as an unequal or null pair of elements is found. If either of this pair of elements is null, the result of the row comparison is unknown (null); otherwise comparison of this pair of elements determines the result. For example, ROW(1, 2, NULL) < ROW(1, 3, 0) yields true, not null, because the third pair of elements are not considered.

**Note:** Prior to PostgreSQL 8.2, the <, <=, > and >= cases were not handled per SQL specification. A comparison like ROW(a, b) < ROW(c, d) was implemented as a < c AND b < d whereas the correct behavior is equivalent to a < c OR (a = c AND b < d).

*row\_constructor IS DISTINCT FROM row\_constructor*

This construct is similar to a <> row comparison, but it does not yield null for null inputs. Instead, any null value is considered unequal to (distinct from) any non-null value, and any two nulls are considered equal (not distinct). Thus the result will always be either true or false, never null.

*row\_constructor IS NOT DISTINCT FROM row\_constructor*

This construct is similar to a = row comparison, but it does not yield null for null inputs. Instead, any null value is considered unequal to (distinct from) any non-null value, and any two nulls are considered equal (not distinct). Thus the result will always be either true or false, never null.

## 9.21. Set Returning Functions

This section describes functions that possibly return more than one row. Currently the only functions in this class are series generating functions, as detailed in Table 9-43.

**Table 9-43. Series Generating Functions**

Function	Argument Type	Return Type	Description
<code>generate_series(start, stop)</code>	int or bigint	setof int or setof bigint (same as argument type)	Generate a series of values, from <code>start</code> to <code>stop</code> with a step size of one
<code>generate_series(start, stop, step)</code>	int or bigint	setof int or setof bigint (same as argument type)	Generate a series of values, from <code>start</code> to <code>stop</code> with a step size of <code>step</code>

When `step` is positive, zero rows are returned if `start` is greater than `stop`. Conversely, when `step` is negative, zero rows are returned if `start` is less than `stop`. Zero rows are also returned for NULL inputs. It is an error for `step` to be zero. Some examples follow:

```
select * from generate_series(2,4);
generate_series
```

```
-----
                2
                3
                4
```

(3 rows)

```
select * from generate_series(5,1,-2);
generate_series
```

```
-----
                5
                3
                1
```

(3 rows)

```
select * from generate_series(4,3);
generate_series
```

```
-----
(0 rows)
```

```
select current_date + s.a as dates from generate_series(0,14,7) as s(a);
dates
```

```

-----
2004-02-05
2004-02-12
2004-02-19
(3 rows)

```

## 9.22. System Information Functions

Table 9-44 shows several functions that extract session and system information.

In addition to the functions listed in this section, there are a number of functions related to the statistics system that also provide system information. See Section 26.2.2 for more information.

**Table 9-44. Session Information Functions**

Name	Return Type	Description
<code>current_database()</code>	name	name of current database
<code>current_schema()</code>	name	name of current schema
<code>current_schemas(boolean)</code>	name[]	names of schemas in search path optionally including implicit schemas
<code>current_user</code>	name	user name of current execution context
<code>inet_client_addr()</code>	inet	address of the remote connection
<code>inet_client_port()</code>	int	port of the remote connection
<code>inet_server_addr()</code>	inet	address of the local connection
<code>inet_server_port()</code>	int	port of the local connection
<code>pg_my_temp_schema()</code>	oid	OID of session's temporary schema, or 0 if none
<code>pg_is_other_temp_schema(oid)</code>	boolean	is schema another session's temporary schema?
<code>pg_postmaster_start_time()</code>	timestamp with time zone	server start time
<code>session_user</code>	name	session user name
<code>user</code>	name	equivalent to <code>current_user</code>
<code>version()</code>	text	PostgreSQL version information

The `session_user` is normally the user who initiated the current database connection; but superusers can change this setting with *SET SESSION AUTHORIZATION*. The `current_user` is the user identifier that is applicable for permission checking. Normally, it is equal to the session user, but it can be changed with *SET ROLE*. It also changes during the execution of functions with the attribute `SECURITY DEFINER`. In Unix parlance, the session user is the “real user” and the current user is the “effective user”.

**Note:** `current_user`, `session_user`, and `user` have special syntactic status in SQL: they must be

called without trailing parentheses.

`current_schema` returns the name of the schema that is at the front of the search path (or a null value if the search path is empty). This is the schema that will be used for any tables or other named objects that are created without specifying a target schema. `current_schemas(boolean)` returns an array of the names of all schemas presently in the search path. The Boolean option determines whether or not implicitly included system schemas such as `pg_catalog` are included in the search path returned.

**Note:** The search path can be altered at run time. The command is:

```
SET search_path TO schema [, schema, ...]
```

`inet_client_addr` returns the IP address of the current client, and `inet_client_port` returns the port number. `inet_server_addr` returns the IP address on which the server accepted the current connection, and `inet_server_port` returns the port number. All these functions return NULL if the current connection is via a Unix-domain socket.

`pg_my_temp_schema` returns the OID of the current session's temporary schema, or 0 if it has none (because it has not created any temporary tables). `pg_is_other_temp_schema` returns true if the given OID is the OID of any other session's temporary schema. (This can be useful, for example, to exclude other sessions' temporary tables from a catalog display.)

`pg_postmaster_start_time` returns the timestamp with time zone when the server started.

`version` returns a string describing the PostgreSQL server's version.

Table 9-45 lists functions that allow the user to query object access privileges programmatically. See Section 5.6 for more information about privileges.

**Table 9-45. Access Privilege Inquiry Functions**

Name	Return Type	Description
<code>has_database_privilege(user, database, privilege)</code>	boolean	does user have privilege for database
<code>has_database_privilege(database, privilege)</code>	boolean	does current user have privilege for database
<code>has_function_privilege(user, function, privilege)</code>	boolean	does user have privilege for function
<code>has_function_privilege(function, privilege)</code>	boolean	does current user have privilege for function
<code>has_language_privilege(user, language, privilege)</code>	boolean	does user have privilege for language
<code>has_language_privilege(language, privilege)</code>	boolean	does current user have privilege for language

Name	Return Type	Description
<code>has_schema_privilege(user, schema, privilege)</code>	boolean	does user have privilege for schema
<code>has_schema_privilege(schema, privilege)</code>	boolean	does current user have privilege for schema
<code>has_table_privilege(user, table, privilege)</code>	boolean	does user have privilege for table
<code>has_table_privilege(table, privilege)</code>	boolean	does current user have privilege for table
<code>has_tablespace_privilege(user, tablespace, privilege)</code>	boolean	does user have privilege for tablespace
<code>has_tablespace_privilege(tablespace, privilege)</code>	boolean	does current user have privilege for tablespace
<code>pg_has_role(user, role, privilege)</code>	boolean	does user have privilege for role
<code>pg_has_role(role, privilege)</code>	boolean	does current user have privilege for role

`has_database_privilege` checks whether a user can access a database in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. The desired access privilege type must evaluate to `CREATE`, `CONNECT`, `TEMPORARY`, or `TEMP` (which is equivalent to `TEMPORARY`).

`has_function_privilege` checks whether a user can access a function in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. When specifying a function by a text string rather than by OID, the allowed input is the same as for the `regprocedure` data type (see Section 8.16). The desired access privilege type must evaluate to `EXECUTE`. An example is:

```
SELECT has_function_privilege('joeuser', 'myfunc(int, text)', 'execute');
```

`has_language_privilege` checks whether a user can access a procedural language in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. The desired access privilege type must evaluate to `USAGE`.

`has_schema_privilege` checks whether a user can access a schema in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. The desired access privilege type must evaluate to `CREATE` or `USAGE`.

`has_table_privilege` checks whether a user can access a table in a particular way. The user can be specified by name or by OID (`pg_authid.oid`), or if the argument is omitted `current_user` is assumed. The table can be specified by name or by OID. (Thus, there are actually six variants of `has_table_privilege`, which can be distinguished by the number and types of their arguments.) When specifying by name, the name can be schema-qualified if necessary. The desired access privilege type is specified by a text string, which must evaluate to one of the values `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REFERENCES`, or `TRIGGER`. (Case of the string is not significant, however.) An example is:

```
SELECT has_table_privilege('myschema.mytable', 'select');
```

`has_tablespace_privilege` checks whether a user can access a tablespace in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. The desired access privilege type must evaluate to `CREATE`.

`pg_has_role` checks whether a user can access a role in a particular way. The possibilities for its arguments are analogous to `has_table_privilege`. The desired access privilege type must evaluate to `MEMBER` or `USAGE`. `MEMBER` denotes direct or indirect membership in the role (that is, the right to do `SET ROLE`), while `USAGE` denotes whether the privileges of the role are immediately available without doing `SET ROLE`.

To test whether a user holds a grant option on the privilege, append `WITH GRANT OPTION` to the privilege key word; for example `'UPDATE WITH GRANT OPTION'`.

Table 9-46 shows functions that determine whether a certain object is *visible* in the current schema search path. For example, a table is said to be visible if its containing schema is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables:

```
SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

**Table 9-46. Schema Visibility Inquiry Functions**

Name	Return Type	Description
<code>pg_conversion_is_visible(conversion_oid)</code>	boolean	is conversion visible in search path
<code>pg_function_is_visible(function_oid)</code>	boolean	is function visible in search path
<code>pg_operator_is_visible(operator_oid)</code>	boolean	is operator visible in search path
<code>pg_opclass_is_visible(opclass_oid)</code>	boolean	is operator class visible in search path
<code>pg_table_is_visible(table_oid)</code>	boolean	is table visible in search path
<code>pg_ts_config_is_visible(config_oid)</code>	boolean	is text search configuration visible in search path
<code>pg_ts_dict_is_visible(dict_oid)</code>	boolean	is text search dictionary visible in search path
<code>pg_ts_parser_is_visible(parser_oid)</code>	boolean	is text search parser visible in search path
<code>pg_ts_template_is_visible(template_oid)</code>	boolean	is text search template visible in search path
<code>pg_type_is_visible(type_oid)</code>	boolean	is type (or domain) visible in search path

Each function performs the visibility check for one type of database object. Note that `pg_table_is_visible` can also be used with views, indexes and sequences; `pg_type_is_visible`

can also be used with domains. For functions and operators, an object in the search path is visible if there is no object of the same name *and argument data type(s)* earlier in the path. For operator classes, both name and associated index access method are considered.

All these functions require object OIDs to identify the object to be checked. If you want to test an object by name, it is convenient to use the OID alias types (`regclass`, `regtype`, `regprocedure`, `regoperator`, `regconfig`, or `regdictionary`), for example:

```
SELECT pg_type_is_visible('myschema.widget'::regtype);
```

Note that it would not make much sense to test an unqualified name in this way — if the name can be recognized at all, it must be visible.

Table 9-47 lists functions that extract information from the system catalogs.

**Table 9-47. System Catalog Information Functions**

Name	Return Type	Description
<code>format_type(type_oid, typemod)</code>	text	get SQL name of a data type
<code>pg_get_constraintdef(constraint_oid)</code>	text	get definition of a constraint
<code>pg_get_constraintdef(constraint_oid, pretty_bool)</code>	text	get definition of a constraint
<code>pg_get_expr(expr_text, relation_oid)</code>	text	decompile internal form of an expression, assuming that any Vars in it refer to the relation indicated by the second parameter
<code>pg_get_expr(expr_text, relation_oid, pretty_bool)</code>	text	decompile internal form of an expression, assuming that any Vars in it refer to the relation indicated by the second parameter
<code>pg_get_indexdef(index_oid)</code>	text	get CREATE INDEX command for index
<code>pg_get_indexdef(index_oid, column_no, pretty_bool)</code>	text	get CREATE INDEX command for index, or definition of just one index column when <code>column_no</code> is not zero
<code>pg_get_ruledef(rule_oid)</code>	text	get CREATE RULE command for rule
<code>pg_get_ruledef(rule_oid, pretty_bool)</code>	text	get CREATE RULE command for rule
<code>pg_get_serial_sequence(table_name, column_name)</code>	text	get name of the sequence that a serial or bigserial column uses

Name	Return Type	Description
<code>pg_get_triggerdef(trigger_oid)</code>	text	get CREATE [ CONSTRAINT ] TRIGGER command for trigger
<code>pg_get_userbyid(roleid)</code>	name	get role name with given ID
<code>pg_get_viewdef(view_name)</code>	text	get underlying SELECT command for view ( <i>deprecated</i> )
<code>pg_get_viewdef(view_name, pretty_bool)</code>	text	get underlying SELECT command for view ( <i>deprecated</i> )
<code>pg_get_viewdef(view_oid)</code>	text	get underlying SELECT command for view
<code>pg_get_viewdef(view_oid, pretty_bool)</code>	text	get underlying SELECT command for view
<code>pg_tablespace_databases(tablespace_oid)</code>	set of oid	get the set of database OIDs that have objects in the tablespace

`format_type` returns the SQL name of a data type that is identified by its type OID and possibly a type modifier. Pass NULL for the type modifier if no specific modifier is known.

`pg_get_constraintdef`, `pg_get_indexdef`, `pg_get_ruledef`, and `pg_get_triggerdef`, respectively reconstruct the creating command for a constraint, index, rule, or trigger. (Note that this is a decompiled reconstruction, not the original text of the command.) `pg_get_expr` decompiles the internal form of an individual expression, such as the default value for a column. It can be useful when examining the contents of system catalogs. `pg_get_viewdef` reconstructs the SELECT query that defines a view. Most of these functions come in two variants, one of which can optionally “pretty-print” the result. The pretty-printed format is more readable, but the default format is more likely to be interpreted the same way by future versions of PostgreSQL; avoid using pretty-printed output for dump purposes. Passing `false` for the pretty-print parameter yields the same result as the variant that does not have the parameter at all.

`pg_get_serial_sequence` returns the name of the sequence associated with a column, or NULL if no sequence is associated with the column. The first input parameter is a table name with optional schema, and the second parameter is a column name. Because the first parameter is potentially a schema and table, it is not treated as a double-quoted identifier, meaning it is lowercased by default, while the second parameter, being just a column name, is treated as double-quoted and has its case preserved. The function returns a value suitably formatted for passing to the sequence functions (see Section 9.15). This association can be modified or removed with `ALTER SEQUENCE OWNED BY`. (The function probably should have been called `pg_get_owned_sequence`; its name reflects the fact that it’s typically used with `serial` or `bigserial` columns.)

`pg_get_userbyid` extracts a role’s name given its OID.

`pg_tablespace_databases` allows a tablespace to be examined. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows, the tablespace is not empty and cannot be dropped. To display the specific objects populating the tablespace, you will need to connect to the databases identified by `pg_tablespace_databases` and query their `pg_class` catalogs.

The functions shown in Table 9-48 extract comments previously stored with the `COMMENT` command. A null value is returned if no comment could be found matching the specified parameters.

**Table 9-48. Comment Information Functions**

Name	Return Type	Description
<code>col_description(table_oid, column_number)</code>	text	get comment for a table column
<code>obj_description(object_oid, catalog_name)</code>	text	get comment for a database object
<code>obj_description(object_oid)</code>	text	get comment for a database object ( <i>deprecated</i> )
<code>shobj_description(object_oid, catalog_name)</code>	text	get comment for a shared database object

`col_description` returns the comment for a table column, which is specified by the OID of its table and its column number. `obj_description` cannot be used for table columns since columns do not have OIDs of their own.

The two-parameter form of `obj_description` returns the comment for a database object specified by its OID and the name of the containing system catalog. For example, `obj_description(123456, 'pg_class')` would retrieve the comment for a table with OID 123456. The one-parameter form of `obj_description` requires only the object OID. It is now deprecated since there is no guarantee that OIDs are unique across different system catalogs; therefore, the wrong comment could be returned.

`shobj_description` is used just like `obj_description` only that it is used for retrieving comments on shared objects. Some system catalogs are global to all databases within each cluster and their descriptions are stored globally as well.

The functions shown in Table 9-49 export server internal transaction information to user level. The main use of these functions is to determine which transactions were committed between two snapshots.

**Table 9-49. Transaction IDs and snapshots**

Name	Return Type	Description
<code>txid_current()</code>	bigint	get current transaction ID
<code>txid_current_snapshot()</code>	txid_snapshot	get current snapshot
<code>txid_snapshot_xmin(txid_snapshot)</code>	bigint	get xmin of snapshot
<code>txid_snapshot_xmax(txid_snapshot)</code>	bigint	get xmax of snapshot
<code>txid_snapshot_xip(txid_snapshot)</code>	set of bigint	get in-progress transaction IDs in snapshot
<code>txid_visible_in_snapshot(bigint, txid_snapshot)</code>	boolean	is transaction ID visible in snapshot?

The internal transaction ID type (xid) is 32 bits wide and so it wraps around every 4 billion transactions. However, these functions export a 64-bit format that is extended with an “epoch” counter so that it will not wrap around for the life of an installation. The data type used by these functions, `txid_snapshot`, stores information about transaction ID visibility at a particular moment in time. Its components are described

in Table 9-50.

**Table 9-50. Snapshot components**

Name	Description
<code>xmin</code>	Earliest transaction ID (txid) that is still active. All earlier transactions will either be committed and visible, or rolled back and dead.
<code>xmax</code>	First as-yet-unassigned txid. All txids later than this one are not yet started as of the time of the snapshot, and thus invisible.
<code>xip_list</code>	Active txids at the time of the snapshot. All of them are between <code>xmin</code> and <code>xmax</code> . A txid that is <code>xmin &lt;= txid &lt; xmax</code> and not in this list was already completed at the time of the snapshot, and thus either visible or dead according to its commit status.

`txid_snapshot`'s textual representation is `xmin:xmax:xip_list`. For example `10:20:10,14,15` means `xmin=10`, `xmax=20`, `xip_list=10, 14, 15`.

## 9.23. System Administration Functions

Table 9-51 shows the functions available to query and alter run-time configuration parameters.

**Table 9-51. Configuration Settings Functions**

Name	Return Type	Description
<code>current_setting(setting_name)</code>	text	current value of setting
<code>set_config(setting_name, new_value, is_local)</code>	text	set parameter and return new value

The function `current_setting` yields the current value of the setting `setting_name`. It corresponds to the SQL command `SHOW`. An example:

```
SELECT current_setting('datestyle');
```

```
current_setting
-----
ISO, MDY
(1 row)
```

`set_config` sets the parameter `setting_name` to `new_value`. If `is_local` is `true`, the new value will only apply to the current transaction. If you want the new value to apply for the current session, use `false` instead. The function corresponds to the SQL command `SET`. An example:

```
SELECT set_config('log_statement_stats', 'off', false);
```

```
set_config
-----
off
(1 row)
```

The functions shown in Table 9-52 send control signals to other server processes. Use of these functions is restricted to superusers.

**Table 9-52. Server Signalling Functions**

Name	Return Type	Description
<code>pg_cancel_backend(pid int)</code>	boolean	Cancel a backend's current query
<code>pg_reload_conf()</code>	boolean	Cause server processes to reload their configuration files
<code>pg_rotate_logfile()</code>	boolean	Rotate server's log file

Each of these functions returns `true` if successful and `false` otherwise.

`pg_cancel_backend` sends a query cancel (SIGINT) signal to a backend process identified by process ID. The process ID of an active backend can be found from the `procpid` column in the `pg_stat_activity` view, or by listing the `postgres` processes on the server with `ps`.

`pg_reload_conf` sends a SIGHUP signal to the server, causing the configuration files to be reloaded by all server processes.

`pg_rotate_logfile` signals the log-file manager to switch to a new output file immediately. This works only when the built-in log collector is running, since otherwise there is no log-file manager subprocess.

The functions shown in Table 9-53 assist in making on-line backups. Use of the first three functions is restricted to superusers.

**Table 9-53. Backup Control Functions**

Name	Return Type	Description
<code>pg_start_backup(label text)</code>	text	Set up for performing on-line backup
<code>pg_stop_backup()</code>	text	Finish performing on-line backup
<code>pg_switch_xlog()</code>	text	Force switch to a new transaction log file

Name	Return Type	Description
<code>pg_current_xlog_location()</code>	text	Get current transaction log write location
<code>pg_current_xlog_insert_location()</code>	text	Get current transaction log insert location
<code>pg_xlogfile_name_offset(location text)</code>	text, integer	Convert transaction log location string to file name and decimal byte offset within file
<code>pg_xlogfile_name(location text)</code>	text	Convert transaction log location string to file name

`pg_start_backup` accepts a single parameter which is an arbitrary user-defined label for the backup. (Typically this would be the name under which the backup dump file will be stored.) The function writes a backup label file into the database cluster's data directory, and then returns the backup's starting transaction log location as text. The user need not pay any attention to this result value, but it is provided in case it is of use.

```
postgres=# select pg_start_backup('label_goes_here');
pg_start_backup
-----
0/D4445B8
(1 row)
```

`pg_stop_backup` removes the label file created by `pg_start_backup`, and instead creates a backup history file in the transaction log archive area. The history file includes the label given to `pg_start_backup`, the starting and ending transaction log locations for the backup, and the starting and ending times of the backup. The return value is the backup's ending transaction log location (which again might be of little interest). After noting the ending location, the current transaction log insertion point is automatically advanced to the next transaction log file, so that the ending transaction log file can be archived immediately to complete the backup.

`pg_switch_xlog` moves to the next transaction log file, allowing the current file to be archived (assuming you are using continuous archiving). The result is the ending transaction log location within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switch, `pg_switch_xlog` does nothing and returns the end location of the previous transaction log file.

`pg_current_xlog_location` displays the current transaction log write location in the same format used by the above functions. Similarly, `pg_current_xlog_insert_location` displays the current transaction log insertion point. The insertion point is the “logical” end of the transaction log at any instant, while the write location is the end of what has actually been written out from the server's internal buffers. The write location is the end of what can be examined from outside the server, and is usually what you want if you are interested in archiving partially-complete transaction log files. The insertion point is made available primarily for server debugging purposes. These are both read-only operations and do not require superuser permissions.

You can use `pg_xlogfile_name_offset` to extract the corresponding transaction log file name and byte offset from the results of any of the above functions. For example:

```

postgres=# select * from pg_xlogfile_name_offset(pg_stop_backup());
      file_name      | file_offset
-----+-----
00000001000000000000000D |      4039624
(1 row)

```

Similarly, `pg_xlogfile_name` extracts just the transaction log file name. When the given transaction log location is exactly at a transaction log file boundary, both these functions return the name of the preceding transaction log file. This is usually the desired behavior for managing transaction log archiving behavior, since the preceding file is the last one that currently needs to be archived.

For details about proper usage of these functions, see Section 24.3.

The functions shown in Table 9-54 calculate the actual disk space usage of database objects.

**Table 9-54. Database Object Size Functions**

Name	Return Type	Description
<code>pg_column_size(any)</code>	int	Number of bytes used to store a particular value (possibly compressed)
<code>pg_database_size(oid)</code>	bigint	Disk space used by the database with the specified OID
<code>pg_database_size(name)</code>	bigint	Disk space used by the database with the specified name
<code>pg_relation_size(oid)</code>	bigint	Disk space used by the table or index with the specified OID
<code>pg_relation_size(text)</code>	bigint	Disk space used by the table or index with the specified name. The table name can be qualified with a schema name
<code>pg_size_pretty(bigint)</code>	text	Converts a size in bytes into a human-readable format with size units
<code>pg_tablespace_size(oid)</code>	bigint	Disk space used by the tablespace with the specified OID
<code>pg_tablespace_size(name)</code>	bigint	Disk space used by the tablespace with the specified name
<code>pg_total_relation_size(oid)</code>	bigint	Total disk space used by the table with the specified OID, including indexes and toasted data

Name	Return Type	Description
<code>pg_total_relation_size(text)</code>	<code>bigint</code>	Total disk space used by the table with the specified name, including indexes and toasted data. The table name can be qualified with a schema name

`pg_column_size` shows the space used to store any individual data value.

`pg_database_size` and `pg_tablespace_size` accept the OID or name of a database or tablespace, and return the total disk space used therein.

`pg_relation_size` accepts the OID or name of a table, index or toast table, and returns the size in bytes.

`pg_size_pretty` can be used to format the result of one of the other functions in a human-readable way, using kB, MB, GB or TB as appropriate.

`pg_total_relation_size` accepts the OID or name of a table or toast table, and returns the size in bytes of the data and all associated indexes and toast tables.

The functions shown in Table 9-55 provide native file access to files on the machine hosting the server. Only files within the database cluster directory and the `log_directory` can be accessed. Use a relative path for files within the cluster directory, and a path matching the `log_directory` configuration setting for log files. Use of these functions is restricted to superusers.

**Table 9-55. Generic File Access Functions**

Name	Return Type	Description
<code>pg_ls_dir(dirname text)</code>	<code>setof text</code>	List the contents of a directory
<code>pg_read_file(filename text, offset bigint, length bigint)</code>	<code>text</code>	Return the contents of a text file
<code>pg_stat_file(filename text)</code>	<code>record</code>	Return information about a file

`pg_ls_dir` returns all the names in the specified directory, except the special entries “.” and “..”.

`pg_read_file` returns part of a text file, starting at the given `offset`, returning at most `length` bytes (less if the end of file is reached first). If `offset` is negative, it is relative to the end of the file.

`pg_stat_file` returns a record containing the file size, last accessed time stamp, last modified time stamp, last file status change time stamp (Unix platforms only), file creation time stamp (Windows only), and a `boolean` indicating if it is a directory. Typical usages include:

```
SELECT * FROM pg_stat_file('filename');
SELECT (pg_stat_file('filename')).modification;
```

The functions shown in Table 9-56 manage advisory locks. For details about proper usage of these functions, see Section 13.3.4.

**Table 9-56. Advisory Lock Functions**

Name	Return Type	Description
<code>pg_advisory_lock(key bigint)</code>	void	Obtain exclusive advisory lock
<code>pg_advisory_lock(key1 int, key2 int)</code>	void	Obtain exclusive advisory lock
<code>pg_advisory_lock_shared(key bigint)</code>	void	Obtain shared advisory lock
<code>pg_advisory_lock_shared(key1 int, key2 int)</code>	void	Obtain shared advisory lock
<code>pg_try_advisory_lock(key bigint)</code>	boolean	Obtain exclusive advisory lock if available
<code>pg_try_advisory_lock(key1 int, key2 int)</code>	boolean	Obtain exclusive advisory lock if available
<code>pg_try_advisory_lock_shared(key bigint)</code>	boolean	Obtain shared advisory lock if available
<code>pg_try_advisory_lock_shared(key1 int, key2 int)</code>	boolean	Obtain shared advisory lock if available
<code>pg_advisory_unlock(key bigint)</code>	boolean	Release an exclusive advisory lock
<code>pg_advisory_unlock(key1 int, key2 int)</code>	boolean	Release an exclusive advisory lock
<code>pg_advisory_unlock_shared(key bigint)</code>	boolean	Release a shared advisory lock
<code>pg_advisory_unlock_shared(key1 int, key2 int)</code>	boolean	Release a shared advisory lock
<code>pg_advisory_unlock_all()</code>	void	Release all advisory locks held by the current session

`pg_advisory_lock` locks an application-defined resource, which can be identified either by a single 64-bit key value or two 32-bit key values (note that these two key spaces do not overlap). If another session already holds a lock on the same resource, the function will wait until the resource becomes available. The lock is exclusive. Multiple lock requests stack, so that if the same resource is locked three times it must be also unlocked three times to be released for other sessions' use.

`pg_advisory_lock_shared` works the same as `pg_advisory_lock`, except the lock can be shared with other sessions requesting shared locks. Only would-be exclusive lockers are locked out.

`pg_try_advisory_lock` is similar to `pg_advisory_lock`, except the function will not wait for the lock to become available. It will either obtain the lock immediately and return `true`, or return `false` if

the lock cannot be acquired now.

`pg_try_advisory_lock_shared` works the same as `pg_try_advisory_lock`, except it attempts to acquire shared rather than exclusive lock.

`pg_advisory_unlock` will release a previously-acquired exclusive advisory lock. It will return `true` if the lock is successfully released. If the lock was in fact not held, it will return `false`, and in addition, an SQL warning will be raised by the server.

`pg_advisory_unlock_shared` works the same as `pg_advisory_unlock`, except to release a shared advisory lock.

`pg_advisory_unlock_all` will release all advisory locks held by the current session. (This function is implicitly invoked at session end, even if the client disconnects ungracefully.)

# Chapter 10. Type Conversion

SQL statements can, intentionally or not, require mixing of different data types in the same expression. PostgreSQL has extensive facilities for evaluating mixed-type expressions.

In many cases a user will not need to understand the details of the type conversion mechanism. However, the implicit conversions done by PostgreSQL can affect the results of a query. When necessary, these results can be tailored by using *explicit* type conversion.

This chapter introduces the PostgreSQL type conversion mechanisms and conventions. Refer to the relevant sections in Chapter 8 and Chapter 9 for more information on specific data types and allowed functions and operators.

## 10.1. Overview

SQL is a strongly typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. PostgreSQL has an extensible type system that is much more general and flexible than other SQL implementations. Hence, most type conversion behavior in PostgreSQL is governed by general rules rather than by *ad hoc* heuristics. This allows mixed-type expressions to be meaningful even with user-defined types.

The PostgreSQL scanner/parser divides lexical elements into only five fundamental categories: integers, non-integer numbers, strings, identifiers, and key words. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with strings, and this mechanism can be used in PostgreSQL to start the parser down the correct path. For example, the query

```
SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
```

```
label | value
-----+-----
Origin | (0,0)
(1 row)
```

has two literal constants, of type `text` and `point`. If a type is not specified for a string literal, then the placeholder type `unknown` is assigned initially, to be resolved in later stages as described below.

There are four fundamental SQL constructs requiring distinct type conversion rules in the PostgreSQL parser:

### Function calls

Much of the PostgreSQL type system is built around a rich set of functions. Functions can have one or more arguments. Since PostgreSQL permits function overloading, the function name alone does not uniquely identify the function to be called; the parser must select the right function based on the data types of the supplied arguments.

### Operators

PostgreSQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, and so the same problem of selecting the right operator exists.

## Value Storage

SQL `INSERT` and `UPDATE` statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.

## UNION, CASE, and related constructs

Since all query results from a unionized `SELECT` statement must appear in a single set of columns, the types of the results of each `SELECT` clause must be matched up and converted to a uniform set. Similarly, the result expressions of a `CASE` construct must be converted to a common type so that the `CASE` expression as a whole has a known output type. The same holds for `ARRAY` constructs, and for the `GREATEST` and `LEAST` functions.

The system catalogs store information about which conversions, called *casts*, between data types are valid, and how to perform those conversions. Additional casts can be added by the user with the `CREATE CAST` command. (This is usually done in conjunction with defining new data types. The set of casts between the built-in types has been carefully crafted and is best not altered.)

An additional heuristic is provided in the parser to allow better guesses at proper behavior for SQL standard types. There are several basic *type categories* defined: `boolean`, `numeric`, `string`, `bitstring`, `datetime`, `timespan`, `geometric`, `network`, and `user-defined`. Each category, with the exception of `user-defined`, has one or more *preferred types* which are preferentially selected when there is ambiguity. In the `user-defined` category, each type is its own preferred type. Ambiguous expressions (those with multiple candidate parsing solutions) can therefore often be resolved when there are multiple possible built-in types, but they will raise an error when there are multiple choices for `user-defined` types.

All type conversion rules are designed with several principles in mind:

- Implicit conversions should never have surprising or unpredictable outcomes.
- User-defined types, of which the parser has no *a priori* knowledge, should be “higher” in the type hierarchy. In mixed-type expressions, native types shall always be converted to a user-defined type (of course, only if conversion is necessary).
- User-defined types are not related. Currently, PostgreSQL does not have information available to it on relationships between types, other than hardcoded heuristics for built-in types and implicit relationships based on available functions and casts.
- There should be no extra overhead from the parser or executor if a query does not need implicit type conversion. That is, if a query is well formulated and the types already match up, then the query should proceed without spending extra time in the parser and without introducing unnecessary implicit conversion calls into the query.

Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function and will no longer do the implicit conversion using the old function.

## 10.2. Operators

The specific operator to be used in an operator invocation is determined by following the procedure below. Note that this procedure is indirectly affected by the precedence of the involved operators. See Section 4.1.6 for more information.

### Operator Type Resolution

1. Select the operators to be considered from the `pg_operator` system catalog. If an unqualified operator name was used (the usual case), the operators considered are those of the right name and argument count that are visible in the current search path (see Section 5.7.3). If a qualified operator name was given, only operators in the specified schema are considered.
  - a. If the search path finds multiple operators of identical argument types, only the one appearing earliest in the path is considered. But operators of different argument types are considered on an equal footing regardless of search path position.
2. Check for an operator accepting exactly the input argument types. If one exists (there can be only one exact match in the set of operators considered), use it.
  - a. If one argument of a binary operator invocation is of the `unknown` type, then assume it is the same type as the other argument for this check. Other cases involving `unknown` will never find a match at this step.
3. Look for the best match.
  - a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. `unknown` literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. (Domains are considered the same as their base type for this purpose.) Keep all candidates if none have any exact matches. If only one candidate remains, use it; else continue to the next step.
  - c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accept preferred types. If only one candidate remains, use it; else continue to the next step.
  - d. If any input arguments are `unknown`, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the `string` category if any candidate accepts that category. (This bias towards string is appropriate since an `unknown`-type literal does look like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type at a given argument position, discard candidates that accept non-preferred types for that argument.
  - e. If only one candidate remains, use it. If no candidate or more than one candidate remains, then fail.

Some examples follow.

### Example 10-1. Factorial Operator Type Resolution

There is only one factorial operator (postfix `!`) defined in the standard catalog, and it takes an argument of type `bigint`. The scanner assigns an initial type of `integer` to the argument in this query expression:

```
SELECT 40 ! AS "40 factorial";
```

```

              40 factorial
-----
815915283247897734345611269596115894272000000000
(1 row)
```

So the parser does a type conversion on the operand and the query is equivalent to

```
SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

### Example 10-2. String Concatenation Operator Type Resolution

A string-like syntax is used for working with string types as well as for working with complex extension types. Strings with unspecified type are matched with likely operator candidates.

An example with one unspecified argument:

```
SELECT text 'abc' || 'def' AS "text and unknown";
```

```

text and unknown
-----
abcdef
(1 row)
```

In this case the parser looks to see if there is an operator taking `text` for both arguments. Since there is, it assumes that the second argument should be interpreted as of type `text`.

Here is a concatenation on unspecified types:

```
SELECT 'abc' || 'def' AS "unspecified";
```

```

unspecified
-----
abcdef
(1 row)
```

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, `text`, is used as the specific type to resolve the unknown literals to.

**Example 10-3. Absolute-Value and Negation Operator Type Resolution**

The PostgreSQL operator catalog has several entries for the prefix operator @, all of which implement absolute-value operations for various numeric data types. One of these entries is for type `float8`, which is the preferred type in the numeric category. Therefore, PostgreSQL will use that entry when faced with an unknown input:

```
SELECT @ '-4.5' AS "abs";
      abs
-----
      4.5
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as type `float8` before applying the chosen operator. We can verify that `float8` and not some other type was used:

```
SELECT @ '-4.5e500' AS "abs";
```

```
ERROR:  "-4.5e500" is out of range for type double precision
```

On the other hand, the prefix operator ~ (bitwise negation) is defined only for integer data types, not for `float8`. So, if we try a similar case with ~, we get:

```
SELECT ~ '20' AS "negation";
```

```
ERROR:  operator is not unique: ~ "unknown"
HINT:  Could not choose a best candidate operator. You might need to add
explicit type casts.
```

This happens because the system cannot decide which of the several possible ~ operators should be preferred. We can help it out with an explicit cast:

```
SELECT ~ CAST('20' AS int8) AS "negation";
```

```
      negation
-----
      -21
(1 row)
```

## 10.3. Functions

The specific function to be used in a function invocation is determined according to the following steps.

**Function Type Resolution**

1. Select the functions to be considered from the `pg_proc` system catalog. If an unqualified function name was used, the functions considered are those of the right name and argument count that are visible in the current search path (see Section 5.7.3). If a qualified function name was given, only functions in the specified schema are considered.
  - a. If the search path finds multiple functions of identical argument types, only the one appearing earliest in the path is considered. But functions of different argument types are considered on an equal footing regardless of search path position.

2. Check for a function accepting exactly the input argument types. If one exists (there can be only one exact match in the set of functions considered), use it. (Cases involving `unknown` will never find a match at this step.)
3. If no exact match is found, see whether the function call appears to be a special type conversion request. This happens if the function call has just one argument and the function name is the same as the (internal) name of some data type. Furthermore, the function argument must be either an `unknown`-type literal, or a type that is binary-compatible with the named data type, or a type that could be converted to the named data type by applying that type's I/O functions (that is, the conversion is either to or from one of the standard string types). When these conditions are met, the function call is treated as a form of `CAST` specification.<sup>1</sup>
4. Look for the best match.
  - a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. `unknown` literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. (Domains are considered the same as their base type for this purpose.) Keep all candidates if none have any exact matches. If only one candidate remains, use it; else continue to the next step.
  - c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accept preferred types. If only one candidate remains, use it; else continue to the next step.
  - d. If any input arguments are `unknown`, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the `string` category if any candidate accepts that category. (This bias towards string is appropriate since an `unknown`-type literal does look like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type at a given argument position, discard candidates that accept non-preferred types for that argument.
  - e. If only one candidate remains, use it. If no candidate or more than one candidate remains, then fail.

Note that the “best match” rules are identical for operator and function type resolution. Some examples follow.

---

1. The reason for this step is to support function-style cast specifications in cases where there is not an actual cast function. If there is a cast function, it is conventionally named after its output type, and so there is no need to have a special case. See *CREATE CAST* for additional commentary.

**Example 10-4. Rounding Function Argument Type Resolution**

There is only one `round` function with two arguments. (The first is `numeric`, the second is `integer`.) So the following query automatically converts the first argument of type `integer` to `numeric`:

```
SELECT round(4, 4);
```

```
round
-----
4.0000
(1 row)
```

That query is actually transformed by the parser to

```
SELECT round(CAST (4 AS numeric), 4);
```

Since `numeric` constants with decimal points are initially assigned the type `numeric`, the following query will require no type conversion and might therefore be slightly more efficient:

```
SELECT round(4.0, 4);
```

**Example 10-5. Substring Function Type Resolution**

There are several `substr` functions, one of which takes types `text` and `integer`. If called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category `string` (namely of type `text`).

```
SELECT substr('1234', 3);
```

```
substr
-----
34
(1 row)
```

If the string is declared to be of type `varchar`, as might be the case if it comes from a table, then the parser will try to convert it to become `text`:

```
SELECT substr(varchar '1234', 3);
```

```
substr
-----
34
(1 row)
```

This is transformed by the parser to effectively become

```
SELECT substr(CAST (varchar '1234' AS text), 3);
```

**Note:** The parser learns from the `pg_cast` catalog that `text` and `varchar` are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion call is really inserted in this case.

And, if the function is called with an argument of type `integer`, the parser will try to convert that to `text`:

```
SELECT substr(1234, 3);
ERROR:  function substr(integer, integer) does not exist
HINT:  No function matches the given name and argument types. You might need
to add explicit type casts.
```

This does not work because `integer` does not have an implicit cast to `text`. An explicit cast will work, however:

```
SELECT substr(CAST (1234 AS text), 3);
```

```
      substr
-----
          34
(1 row)
```

## 10.4. Value Storage

Values to be inserted into a table are converted to the destination column's data type according to the following steps.

### Value Storage Type Conversion

1. Check for an exact match with the target.
2. Otherwise, try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the contents of the literal string will be fed to the input conversion routine for the target type.
3. Check to see if there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the `pg_cast` catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type `integer`, which receives the destination column's declared length (actually, its `atttypmod` value; the interpretation of `atttypmod` varies for different data types). The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

### Example 10-6. character Storage Type Conversion

For a target column declared as `character(20)` the following statement ensures that the stored value is sized correctly:

```
CREATE TABLE vv (v character(20));
INSERT INTO vv SELECT 'abc' || 'def';
SELECT v, length(v) FROM vv;
```

```
      v          | length
-----+-----
 abcdef          |      20
```

```
(1 row)
```

What has really happened here is that the two unknown literals are resolved to `text` by default, allowing the `||` operator to be resolved as `text` concatenation. Then the `text` result of the operator is converted to `bpchar` (“blank-padded char”, the internal name of the `character` data type) to match the target column type. (Since the types `text` and `bpchar` are binary-compatible, this conversion does not insert any real function call.) Finally, the sizing function `bpchar(bpchar, integer)` is found in the system catalog and applied to the operator’s result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

## 10.5. UNION, CASE, and Related Constructs

SQL `UNION` constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. The `INTERSECT` and `EXCEPT` constructs resolve dissimilar types in the same way as `UNION`. The `CASE`, `ARRAY`, `VALUES`, `GREATEST` and `LEAST` constructs use the identical algorithm to match up their component expressions and select a result data type.

### Type Resolution for UNION, CASE, and Related Constructs

1. If all inputs are of the same type, and it is not `unknown`, resolve as that type. Otherwise, replace any domain types in the list with their underlying base types.
2. If all inputs are of type `unknown`, resolve as type `text` (the preferred type of the string category). Otherwise, the `unknown` inputs will be ignored.
3. If the non-unknown inputs are not all of the same type category, fail.
4. Choose the first non-unknown input type which is a preferred type in that category, if there is one.
5. Otherwise, choose the last non-unknown input type that allows all the preceding non-unknown inputs to be implicitly converted to it. (There always is such a type, since at least the first type in the list must satisfy this condition.)
6. Convert all inputs to the selected type. Fail if there is not a conversion from a given input to the selected type.

Some examples follow.

#### Example 10-7. Type Resolution with Underspecified Types in a Union

```
SELECT text 'a' AS "text" UNION SELECT 'b';
```

```
text
-----
a
b
(2 rows)
```

Here, the unknown-type literal `'b'` will be resolved as type `text`.

**Example 10-8. Type Resolution in a Simple Union**

```
SELECT 1.2 AS "numeric" UNION SELECT 1;
```

```
numeric
-----
      1
     1.2
(2 rows)
```

The literal `1.2` is of type `numeric`, and the `integer` value `1` can be cast implicitly to `numeric`, so that type is used.

**Example 10-9. Type Resolution in a Transposed Union**

```
SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
```

```
real
-----
      1
     2.2
(2 rows)
```

Here, since type `real` cannot be implicitly cast to `integer`, but `integer` can be implicitly cast to `real`, the union result type is resolved as `real`.

# Chapter 11. Indexes

Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could do without an index. But indexes also add overhead to the database system as a whole, so they should be used sensibly.

## 11.1. Introduction

Suppose we have a table similar to this:

```
CREATE TABLE test1 (  
    id integer,  
    content varchar  
);
```

and the application requires a lot of queries of the form:

```
SELECT content FROM test1 WHERE id = constant;
```

With no advance preparation, the system would have to scan the entire `test1` table, row by row, to find all matching entries. If there are a lot of rows in `test1` and only a few rows (perhaps only zero or one) that would be returned by such a query, then this is clearly an inefficient method. But if the system has been instructed to maintain an index on the `id` column, then it can use a more efficient method for locating matching rows. For instance, it might only have to walk a few levels deep into a search tree.

A similar approach is used in most books of non-fiction: terms and concepts that are frequently looked up by readers are collected in an alphabetic index at the end of the book. The interested reader can scan the index relatively quickly and flip to the appropriate page(s), rather than having to read the entire book to find the material of interest. Just as it is the task of the author to anticipate the items that the readers are likely to look up, it is the task of the database programmer to foresee which indexes will be of advantage.

The following command would be used to create the index on the `id` column, as discussed:

```
CREATE INDEX test1_id_index ON test1 (id);
```

The name `test1_id_index` can be chosen freely, but you should pick something that enables you to remember later what the index was for.

To remove an index, use the `DROP INDEX` command. Indexes can be added to and removed from tables at any time.

Once an index is created, no further intervention is required: the system will update the index when the table is modified, and it will use the index in queries when it thinks this would be more efficient than a sequential table scan. But you might have to run the `ANALYZE` command regularly to update statistics to allow the query planner to make educated decisions. See Chapter 14 for information about how to find out whether an index is used and when and why the planner might choose *not* to use an index.

Indexes can also benefit `UPDATE` and `DELETE` commands with search conditions. Indexes can moreover be used in join searches. Thus, an index defined on a column that is part of a join condition can significantly speed up queries with joins.

Creating an index on a large table can take a long time. By default, PostgreSQL allows reads (selects) to occur on the table in parallel with creation of an index, but writes (inserts, updates, deletes) are blocked until the index build is finished. In production environments this is often unacceptable. It is possible to allow writes to occur in parallel with index creation, but there are several caveats to be aware of — for more information see *Building Indexes Concurrently*.

After an index is created, the system has to keep it synchronized with the table. This adds overhead to data manipulation operations. Therefore indexes that are seldom or never used in queries should be removed.

## 11.2. Index Types

PostgreSQL provides several index types: B-tree, Hash, GiST and GIN. Each index type uses a different algorithm that is best suited to different types of queries. By default, the `CREATE INDEX` command will create a B-tree index, which fits the most common situations.

B-trees can handle equality and range queries on data that can be sorted into some ordering. In particular, the PostgreSQL query planner will consider using a B-tree index whenever an indexed column is involved in a comparison using one of these operators:

```
<
<=
=
>=
>
```

Constructs equivalent to combinations of these operators, such as `BETWEEN` and `IN`, can also be implemented with a B-tree index search. Also, an `IS NULL` condition on an index column can be used with a B-tree index.

The optimizer can also use a B-tree index for queries involving the pattern matching operators `LIKE` and `~` if the pattern is a constant and is anchored to the beginning of the string — for example, `col LIKE 'foo%'` or `col ~ '^foo'`, but not `col LIKE '%bar'`. However, if your server does not use the C locale you will need to create the index with a special operator class to support indexing of pattern-matching queries. See Section 11.9 below. It is also possible to use B-tree indexes for `ILIKE` and `~*`, but only if the pattern starts with non-alphabetic characters, i.e. characters that are not affected by upper/lower case conversion.

Hash indexes can only handle simple equality comparisons. The query planner will consider using a hash index whenever an indexed column is involved in a comparison using the `=` operator. (But hash indexes do not support `IS NULL` searches.) The following command is used to create a hash index:

```
CREATE INDEX name ON table USING hash (column);
```

**Note:** Testing has shown PostgreSQL's hash indexes to perform no better than B-tree indexes, and the index size and build time for hash indexes is much worse. Furthermore, hash index operations are not presently WAL-logged, so hash indexes might need to be rebuilt with `REINDEX` after a database crash. For these reasons, hash index use is presently discouraged.

GiST indexes are not a single kind of index, but rather an infrastructure within which many different indexing strategies can be implemented. Accordingly, the particular operators with which a GiST index can be used vary depending on the indexing strategy (the *operator class*). As an example, the standard distribution of PostgreSQL includes GiST operator classes for several two-dimensional geometric data types, which support indexed queries using these operators:

```
<<
&<
&>
>>
<<|
&<|
|&>
|>>
@>
<@
~=
&&
```

(See Section 9.11 for the meaning of these operators.) Many other GiST operator classes are available in the `contrib` collection or as separate projects. For more information see Chapter 51.

GIN indexes are inverted indexes which can handle values that contain more than one key, arrays for example. Like GiST, GIN can support many different user-defined indexing strategies and the particular operators with which a GIN index can be used vary depending on the indexing strategy. As an example, the standard distribution of PostgreSQL includes GIN operator classes for one-dimensional arrays, which support indexed queries using these operators:

```
<@
@>
=
&&
```

(See Section 9.17 for the meaning of these operators.) Many other GIN operator classes are available in the `contrib` collection or as separate projects. For more information see Chapter 52.

## 11.3. Multicolumn Indexes

An index can be defined on more than one column of a table. For example, if you have a table of this form:

```
CREATE TABLE test2 (
    major int,
    minor int,
    name varchar
);
```

(say, you keep your `/dev` directory in a database...) and you frequently make queries like:

```
SELECT name FROM test2 WHERE major = constant AND minor = constant;
```

then it might be appropriate to define an index on the columns `major` and `minor` together, e.g.:

```
CREATE INDEX test2_mm_idx ON test2 (major, minor);
```

Currently, only the B-tree and GiST index types support multicolumn indexes. Up to 32 columns can be specified. (This limit can be altered when building PostgreSQL; see the file `pg_config_manual.h`.)

A multicolumn B-tree index can be used with query conditions that involve any subset of the index's columns, but the index is most efficient when there are constraints on the leading (leftmost) columns. The exact rule is that equality constraints on leading columns, plus any inequality constraints on the first column that does not have an equality constraint, will be used to limit the portion of the index that is scanned. Constraints on columns to the right of these columns are checked in the index, so they save visits to the table proper, but they do not reduce the portion of the index that has to be scanned. For example, given an index on `(a, b, c)` and a query condition `WHERE a = 5 AND b >= 42 AND c < 77`, the index would have to be scanned from the first entry with `a = 5` and `b = 42` up through the last entry with `a = 5`. Index entries with `c >= 77` would be skipped, but they'd still have to be scanned through. This index could in principle be used for queries that have constraints on `b` and/or `c` with no constraint on `a` — but the entire index would have to be scanned, so in most cases the planner would prefer a sequential table scan over using the index.

A multicolumn GiST index can be used with query conditions that involve any subset of the index's columns. Conditions on additional columns restrict the entries returned by the index, but the condition on the first column is the most important one for determining how much of the index needs to be scanned. A GiST index will be relatively ineffective if its first column has only a few distinct values, even if there are many distinct values in additional columns.

Of course, each column must be used with operators appropriate to the index type; clauses that involve other operators will not be considered.

Multicolumn indexes should be used sparingly. In most situations, an index on a single column is sufficient and saves space and time. Indexes with more than three columns are unlikely to be helpful unless the usage of the table is extremely stylized. See also Section 11.5 for some discussion of the merits of different index setups.

## 11.4. Indexes and ORDER BY

In addition to simply finding the rows to be returned by a query, an index may be able to deliver them in a specific sorted order. This allows a query's `ORDER BY` specification to be met without a separate sorting step. Of the index types currently supported by PostgreSQL, only B-tree can produce sorted output — the other index types return matching rows in an unspecified, implementation-dependent order.

The planner will consider satisfying an `ORDER BY` specification either by scanning any available index that matches the specification, or by scanning the table in physical order and doing an explicit sort. For a query that requires scanning a large fraction of the table, the explicit sort is likely to be faster because it requires less disk I/O due to a better-ordered access pattern. Indexes are more useful when only a few rows need be fetched. An important special case is `ORDER BY` in combination with `LIMIT n`: an explicit

sort will have to process all the data to identify the first  $n$  rows, but if there is an index matching the `ORDER BY` then the first  $n$  rows can be retrieved directly, without scanning the remainder at all.

By default, B-tree indexes store their entries in ascending order with nulls last. This means that a forward scan of an index on a column  $x$  produces output satisfying `ORDER BY x` (or more verbosely, `ORDER BY x ASC NULLS LAST`). The index can also be scanned backward, producing output satisfying `ORDER BY x DESC` (or more verbosely, `ORDER BY x DESC NULLS FIRST`, since `NULLS FIRST` is the default for `ORDER BY DESC`).

You can adjust the ordering of a B-tree index by including the options `ASC`, `DESC`, `NULLS FIRST`, and/or `NULLS LAST` when creating the index; for example:

```
CREATE INDEX test2_info_nulls_low ON test2 (info NULLS FIRST);
CREATE INDEX test3_desc_index ON test3 (id DESC NULLS LAST);
```

An index stored in ascending order with nulls first can satisfy either `ORDER BY x ASC NULLS FIRST` or `ORDER BY x DESC NULLS LAST` depending on which direction it is scanned in.

You might wonder why bother providing all four options, when two options together with the possibility of backward scan would cover all the variants of `ORDER BY`. In single-column indexes the options are indeed redundant, but in multicolumn indexes they can be useful. Consider a two-column index on  $(x, y)$ : this can satisfy `ORDER BY x, y` if we scan forward, or `ORDER BY x DESC, y DESC` if we scan backward. But it might be that the application frequently needs to use `ORDER BY x ASC, y DESC`. There is no way to get that ordering from a regular index, but it is possible if the index is defined as  $(x \text{ ASC}, y \text{ DESC})$  or  $(x \text{ DESC}, y \text{ ASC})$ .

Obviously, indexes with non-default sort orderings are a fairly specialized feature, but sometimes they can produce tremendous speedups for certain queries. Whether it's worth keeping such an index depends on how often you use queries that require a special sort ordering.

## 11.5. Combining Multiple Indexes

A single index scan can only use query clauses that use the index's columns with operators of its operator class and are joined with `AND`. For example, given an index on  $(a, b)$  a query condition like `WHERE a = 5 AND b = 6` could use the index, but a query like `WHERE a = 5 OR b = 6` could not directly use the index.

Beginning in release 8.1, PostgreSQL has the ability to combine multiple indexes (including multiple uses of the same index) to handle cases that cannot be implemented by single index scans. The system can form `AND` and `OR` conditions across several index scans. For example, a query like `WHERE x = 42 OR x = 47 OR x = 53 OR x = 99` could be broken down into four separate scans of an index on  $x$ , each scan using one of the query clauses. The results of these scans are then `ORed` together to produce the result. Another example is that if we have separate indexes on  $x$  and  $y$ , one possible implementation of a query like `WHERE x = 5 AND y = 6` is to use each index with the appropriate query clause and then `AND` together the index results to identify the result rows.

To combine multiple indexes, the system scans each needed index and prepares a *bitmap* in memory giving the locations of table rows that are reported as matching that index's conditions. The bitmaps are then `ANDed` and `ORed` together as needed by the query. Finally, the actual table rows are visited and returned. The table rows are visited in physical order, because that is how the bitmap is laid out; this means that any ordering of the original indexes is lost, and so a separate sort step will be needed if the

query has an `ORDER BY` clause. For this reason, and because each additional index scan adds extra time, the planner will sometimes choose to use a simple index scan even though additional indexes are available that could have been used as well.

In all but the simplest applications, there are various combinations of indexes that might be useful, and the database developer must make trade-offs to decide which indexes to provide. Sometimes multicolumn indexes are best, but sometimes it's better to create separate indexes and rely on the index-combination feature. For example, if your workload includes a mix of queries that sometimes involve only column `x`, sometimes only column `y`, and sometimes both columns, you might choose to create two separate indexes on `x` and `y`, relying on index combination to process the queries that use both columns. You could also create a multicolumn index on `(x, y)`. This index would typically be more efficient than index combination for queries involving both columns, but as discussed in Section 11.3, it would be almost useless for queries involving only `y`, so it could not be the only index. A combination of the multicolumn index and a separate index on `y` would serve reasonably well. For queries involving only `x`, the multicolumn index could be used, though it would be larger and hence slower than an index on `x` alone. The last alternative is to create all three indexes, but this is probably only reasonable if the table is searched much more often than it is updated and all three types of query are common. If one of the types of query is much less common than the others, you'd probably settle for creating just the two indexes that best match the common types.

## 11.6. Unique Indexes

Indexes can also be used to enforce uniqueness of a column's value, or the uniqueness of the combined values of more than one column.

```
CREATE UNIQUE INDEX name ON table (column [, ...]);
```

Currently, only B-tree indexes can be declared unique.

When an index is declared unique, multiple table rows with equal indexed values will not be allowed. Null values are not considered equal. A multicolumn unique index will only reject cases where all of the indexed columns are equal in two rows.

PostgreSQL automatically creates a unique index when a unique constraint or a primary key is defined for a table. The index covers the columns that make up the primary key or unique columns (a multicolumn index, if appropriate), and is the mechanism that enforces the constraint.

**Note:** The preferred way to add a unique constraint to a table is `ALTER TABLE ... ADD CONSTRAINT`. The use of indexes to enforce unique constraints could be considered an implementation detail that should not be accessed directly. One should, however, be aware that there's no need to manually create indexes on unique columns; doing so would just duplicate the automatically-created index.

## 11.7. Indexes on Expressions

An index column need not be just a column of the underlying table, but can be a function or scalar expression computed from one or more columns of the table. This feature is useful to obtain fast access

to tables based on the results of computations.

For example, a common way to do case-insensitive comparisons is to use the `lower` function:

```
SELECT * FROM test1 WHERE lower(coll) = 'value';
```

This query can use an index, if one has been defined on the result of the `lower(coll)` operation:

```
CREATE INDEX test1_lower_coll_idx ON test1 (lower(coll));
```

If we were to declare this index `UNIQUE`, it would prevent creation of rows whose `coll` values differ only in case, as well as rows whose `coll` values are actually identical. Thus, indexes on expressions can be used to enforce constraints that are not definable as simple unique constraints.

As another example, if one often does queries like this:

```
SELECT * FROM people WHERE (first_name || ' ' || last_name) = 'John Smith';
```

then it might be worth creating an index like this:

```
CREATE INDEX people_names ON people ((first_name || ' ' || last_name));
```

The syntax of the `CREATE INDEX` command normally requires writing parentheses around index expressions, as shown in the second example. The parentheses can be omitted when the expression is just a function call, as in the first example.

Index expressions are relatively expensive to maintain, because the derived expression(s) must be computed for each row upon insertion and whenever it is updated. However, the index expressions are *not* recomputed during an indexed search, since they are already stored in the index. In both examples above, the system sees the query as just `WHERE indexedcolumn = 'constant'` and so the speed of the search is equivalent to any other simple index query. Thus, indexes on expressions are useful when retrieval speed is more important than insertion and update speed.

## 11.8. Partial Indexes

A *partial index* is an index built over a subset of a table; the subset is defined by a conditional expression (called the *predicate* of the partial index). The index contains entries for only those table rows that satisfy the predicate. Partial indexes are a specialized feature, but there are several situations in which they are useful.

One major reason for using a partial index is to avoid indexing common values. Since a query searching for a common value (one that accounts for more than a few percent of all the table rows) will not use the index anyway, there is no point in keeping those rows in the index at all. This reduces the size of the index, which will speed up queries that do use the index. It will also speed up many table update operations because the index does not need to be updated in all cases. Example 11-1 shows a possible application of this idea.

**Example 11-1. Setting up a Partial Index to Exclude Common Values**

Suppose you are storing web server access logs in a database. Most accesses originate from the IP address range of your organization but some are from elsewhere (say, employees on dial-up connections). If your searches by IP are primarily for outside accesses, you probably do not need to index the IP range that corresponds to your organization's subnet.

Assume a table like this:

```
CREATE TABLE access_log (
    url varchar,
    client_ip inet,
    ...
);
```

To create a partial index that suits our example, use a command such as this:

```
CREATE INDEX access_log_client_ip_ix ON access_log (client_ip)
    WHERE NOT (client_ip > inet '192.168.100.0' AND client_ip < inet '192.168.100.255');
```

A typical query that can use this index would be:

```
SELECT * FROM access_log WHERE url = '/index.html' AND client_ip = inet '212.78.10.32';
```

A query that cannot use this index is:

```
SELECT * FROM access_log WHERE client_ip = inet '192.168.100.23';
```

Observe that this kind of partial index requires that the common values be predetermined. If the distribution of values is inherent (due to the nature of the application) and static (not changing over time), this is not difficult, but if the common values are merely due to the coincidental data load this can require a lot of maintenance work to change the index definition from time to time.

Another possible use for a partial index is to exclude values from the index that the typical query workload is not interested in; this is shown in Example 11-2. This results in the same advantages as listed above, but it prevents the “uninteresting” values from being accessed via that index at all, even if an index scan might be profitable in that case. Obviously, setting up partial indexes for this kind of scenario will require a lot of care and experimentation.

**Example 11-2. Setting up a Partial Index to Exclude Uninteresting Values**

If you have a table that contains both billed and unbilled orders, where the unbilled orders take up a small fraction of the total table and yet those are the most-accessed rows, you can improve performance by creating an index on just the unbilled rows. The command to create the index would look like this:

```
CREATE INDEX orders_unbilled_index ON orders (order_nr)
    WHERE billed is not true;
```

A possible query to use this index would be:

```
SELECT * FROM orders WHERE billed is not true AND order_nr < 10000;
```

However, the index can also be used in queries that do not involve `order_nr` at all, e.g.:

```
SELECT * FROM orders WHERE billed is not true AND amount > 5000.00;
```

This is not as efficient as a partial index on the `amount` column would be, since the system has to scan the entire index. Yet, if there are relatively few unbilled orders, using this partial index just to find the unbilled orders could be a win.

Note that this query cannot use this index:

```
SELECT * FROM orders WHERE order_nr = 3501;
```

The order 3501 might be among the billed or among the unbilled orders.

Example 11-2 also illustrates that the indexed column and the column used in the predicate do not need to match. PostgreSQL supports partial indexes with arbitrary predicates, so long as only columns of the table being indexed are involved. However, keep in mind that the predicate must match the conditions used in the queries that are supposed to benefit from the index. To be precise, a partial index can be used in a query only if the system can recognize that the `WHERE` condition of the query mathematically implies the predicate of the index. PostgreSQL does not have a sophisticated theorem prover that can recognize mathematically equivalent expressions that are written in different forms. (Not only is such a general theorem prover extremely difficult to create, it would probably be too slow to be of any real use.) The system can recognize simple inequality implications, for example “ $x < 1$ ” implies “ $x < 2$ ”; otherwise the predicate condition must exactly match part of the query’s `WHERE` condition or the index will not be recognized to be usable. Matching takes place at query planning time, not at run time. As a result, parameterized query clauses will not work with a partial index. For example a prepared query with a parameter might specify “ $x < ?$ ” which will never imply “ $x < 2$ ” for all possible values of the parameter.

A third possible use for partial indexes does not require the index to be used in queries at all. The idea here is to create a unique index over a subset of a table, as in Example 11-3. This enforces uniqueness among the rows that satisfy the index predicate, without constraining those that do not.

### Example 11-3. Setting up a Partial Unique Index

Suppose that we have a table describing test outcomes. We wish to ensure that there is only one “successful” entry for a given subject and target combination, but there might be any number of “unsuccessful” entries. Here is one way to do it:

```
CREATE TABLE tests (
    subject text,
    target text,
    success boolean,
    ...
);

CREATE UNIQUE INDEX tests_success_constraint ON tests (subject, target)
    WHERE success;
```

This is a particularly efficient way of doing it when there are few successful tests and many unsuccessful ones.

Finally, a partial index can also be used to override the system’s query plan choices. Also, data sets with peculiar distributions might cause the system to use an index when it really should not. In that case the index can be set up so that it is not available for the offending query. Normally, PostgreSQL makes reasonable choices about index usage (e.g., it avoids them when retrieving common values, so the earlier example really only saves index size, it is not required to avoid index usage), and grossly incorrect plan choices are cause for a bug report.

Keep in mind that setting up a partial index indicates that you know at least as much as the query planner knows, in particular you know when an index might be profitable. Forming this knowledge requires experience and understanding of how indexes in PostgreSQL work. In most cases, the advantage of a partial index over a regular index will not be much.

More information about partial indexes can be found in *The case for partial indexes*, *Partial indexing in POSTGRES: research project*, and *Generalized Partial Indexes (cached version)*.

## 11.9. Operator Classes and Operator Families

An index definition can specify an *operator class* for each column of an index.

```
CREATE INDEX name ON table (column opclass [sort options] [, ...]);
```

The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on the type `int4` would use the `int4_ops` class; this operator class includes comparison functions for values of type `int4`. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful index behavior. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index. The operator class determines the basic sort ordering (which can then be modified by adding sort options `ASC/DESC` and/or `NULLS FIRST/NULLS LAST`).

There are also some built-in operator classes besides the default ones:

- The operator classes `text_pattern_ops`, `varchar_pattern_ops`, `bpchar_pattern_ops`, and `name_pattern_ops` support B-tree indexes on the types `text`, `varchar`, `char`, and `name`, respectively. The difference from the default operator classes is that the values are compared strictly character by character rather than according to the locale-specific collation rules. This makes these operator classes suitable for use by queries involving pattern matching expressions (`LIKE` or POSIX regular expressions) when the server does not use the standard “C” locale. As an example, you might index a `varchar` column like this:

```
CREATE INDEX test_index ON test_table (col varchar_pattern_ops);
```

Note that you should also create an index with the default operator class if you want queries involving ordinary comparisons to use an index. Such queries cannot use the `xxx_pattern_ops` operator classes. It is allowed to create multiple indexes on the same column with different operator classes. If you do use the C locale, you do not need the `xxx_pattern_ops` operator classes, because an index with the default operator class is usable for pattern-matching queries in the C locale.

The following query shows all defined operator classes:

```
SELECT am.amname AS index_method,
       opc.opcname AS opclass_name
FROM pg_am am, pg_opclass opc
WHERE opc.opcmethod = am.oid
ORDER BY index_method, opclass_name;
```

An operator class is actually just a subset of a larger structure called an *operator family*. In cases where several data types have similar behaviors, it is frequently useful to define cross-data-type operators and allow these to work with indexes. To do this, the operator classes for each of the types must be grouped into the same operator family. The cross-type operators are members of the family, but are not associated with any single class within the family.

This query shows all defined operator families and all the operators included in each family:

```
SELECT am.amname AS index_method,
       opf.opfname AS opfamily_name,
       amop.amopr::regoperator AS opfamily_operator
FROM pg_am am, pg_opfamily opf, pg_amop amop
WHERE opf.opfmethod = am.oid AND
      amop.amopfamily = opf.oid
ORDER BY index_method, opfamily_name, opfamily_operator;
```

## 11.10. Examining Index Usage

Although indexes in PostgreSQL do not need maintenance and tuning, it is still important to check which indexes are actually used by the real-life query workload. Examining index usage for an individual query is done with the *EXPLAIN* command; its application for this purpose is illustrated in Section 14.1. It is also possible to gather overall statistics about index usage in a running server, as described in Section 26.2.

It is difficult to formulate a general procedure for determining which indexes to set up. There are a number of typical cases that have been shown in the examples throughout the previous sections. A good deal of experimentation will be necessary in most cases. The rest of this section gives some tips for that.

- Always run *ANALYZE* first. This command collects statistics about the distribution of the values in the table. This information is required to guess the number of rows returned by a query, which is needed by the planner to assign realistic costs to each possible query plan. In absence of any real statistics, some default values are assumed, which are almost certain to be inaccurate. Examining an application's index usage without having run *ANALYZE* is therefore a lost cause.
- Use real data for experimentation. Using test data for setting up indexes will tell you what indexes you need for the test data, but that is all.

It is especially fatal to use very small test data sets. While selecting 1000 out of 100000 rows could be a candidate for an index, selecting 1 out of 100 rows will hardly be, because the 100 rows will probably fit within a single disk page, and there is no plan that can beat sequentially fetching 1 disk page.

Also be careful when making up test data, which is often unavoidable when the application is not in production use yet. Values that are very similar, completely random, or inserted in sorted order will skew the statistics away from the distribution that real data would have.

- When indexes are not used, it can be useful for testing to force their use. There are run-time parameters that can turn off various plan types (see Section 18.6.1). For instance, turning off sequential scans (*enable\_seqscan*) and nested-loop joins (*enable\_nestloop*), which are the most basic plans, will

force the system to use a different plan. If the system still chooses a sequential scan or nested-loop join then there is probably a more fundamental reason why the index is not used; for example, the query condition does not match the index. (What kind of query can use what kind of index is explained in the previous sections.)

- If forcing index usage does use the index, then there are two possibilities: Either the system is right and using the index is indeed not appropriate, or the cost estimates of the query plans are not reflecting reality. So you should time your query with and without indexes. The `EXPLAIN ANALYZE` command can be useful here.
- If it turns out that the cost estimates are wrong, there are, again, two possibilities. The total cost is computed from the per-row costs of each plan node times the selectivity estimate of the plan node. The costs estimated for the plan nodes can be adjusted via run-time parameters (described in Section 18.6.2). An inaccurate selectivity estimate is due to insufficient statistics. It might be possible to improve this by tuning the statistics-gathering parameters (see *ALTER TABLE*).

If you do not succeed in adjusting the costs to be more appropriate, then you might have to resort to forcing index usage explicitly. You might also want to contact the PostgreSQL developers to examine the issue.

# Chapter 12. Full Text Search

## 12.1. Introduction

Full Text Searching (or just *text search*) provides the capability to identify natural-language *documents* that satisfy a *query*, and optionally to sort them by relevance to the query. The most common type of search is to find all documents containing given *query terms* and return them in order of their *similarity* to the query. Notions of *query* and *similarity* are very flexible and depend on the specific application. The simplest search considers *query* as a set of words and *similarity* as the frequency of query words in the document.

Textual search operators have existed in databases for years. PostgreSQL has `~`, `~*`, `LIKE`, and `ILIKE` operators for textual data types, but they lack many essential properties required by modern information systems:

- There is no linguistic support, even for English. Regular expressions are not sufficient because they cannot easily handle derived words, e.g., `satisfies` and `satisfy`. You might miss documents that contain `satisfies`, although you probably would like to find them when searching for `satisfy`. It is possible to use `OR` to search for multiple derived forms, but this is tedious and error-prone (some words can have several thousand derivatives).
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full text indexing allows documents to be *preprocessed* and an index saved for later rapid searching. Preprocessing includes:

*Parsing documents into tokens.* It is useful to identify various classes of tokens, e.g. numbers, words, complex words, email addresses, so that they can be processed differently. In principle token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes. PostgreSQL uses a *parser* to perform this step. A standard parser is provided, and custom parsers can be created for specific needs.

*Converting tokens into lexemes.* A lexeme is a string, just like a token, but it has been *normalized* so that different forms of the same word are made alike. For example, normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as `s` or `es` in English). This allows searches to find variant forms of the same word, without tediously entering all the possible variants. Also, this step typically eliminates *stop words*, which are words that are so common that they are useless for searching. (In short, then, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) PostgreSQL uses *dictionaries* to perform this step. Various standard dictionaries are provided, and custom ones can be created for specific needs.

*Storing preprocessed documents optimized for searching.* For example, each document can be represented as a sorted array of normalized lexemes. Along with the lexemes it is often desirable to store positional information to use for *proximity ranking*, so that a document that contains a more “dense” region of query words is assigned a higher rank than one with scattered query words.

Dictionaries allow fine-grained control over how tokens are normalized. With appropriate dictionaries, you can:

- Define stop words that should not be indexed.
- Map synonyms to a single word using Ispell.
- Map phrases to a single word using a thesaurus.
- Map different variations of a word to a canonical form using an Ispell dictionary.
- Map different variations of a word to a canonical form using Snowball stemmer rules.

A data type `tsvector` is provided for storing preprocessed documents, along with a type `tsquery` for representing processed queries (Section 8.11). There are many functions and operators available for these data types (Section 9.13), the most important of which is the match operator `@@`, which we introduce in Section 12.1.2. Full text searches can be accelerated using indexes (Section 12.9).

### 12.1.1. What Is a Document?

A *document* is the unit of searching in a full text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (key words) with their parent document. Later, these associations are used to search for documents that contain query words.

For searches within PostgreSQL, a document is normally a textual field within a row of a database table, or possibly a combination (concatenation) of such fields, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```
SELECT title || ' ' || author || ' ' || abstract || ' ' || body AS document
FROM messages
WHERE mid = 12;
```

```
SELECT m.title || ' ' || m.author || ' ' || m.abstract || ' ' || d.body AS document
FROM messages m, docs d
WHERE mid = did AND mid = 12;
```

**Note:** Actually, in these example queries, `coalesce` should be used to prevent a single `NULL` attribute from causing a `NULL` result for the whole document.

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store the full text index and to execute searches, and some unique identifier can be used to retrieve the document from the file system. However, retrieving files from outside the database requires superuser permissions or special function support, so this is usually less convenient than keeping all the data inside PostgreSQL. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be reduced to the preprocessed `tsvector` format. Searching and ranking are performed entirely on the `tsvector` representation of a document — the original text need only be retrieved when the document has been selected for display to a user. We therefore often

speak of the `tsvector` as being the document, but of course it is only a compact representation of the full document.

## 12.1.2. Basic Text Matching

Full text searching in PostgreSQL is based on the match operator `@@`, which returns `true` if a `tsvector` (document) matches a `tsquery` (query). It doesn't matter which data type is written first:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector @@ 'cat & rat'::tsquery;
?column?
```

```
-----
t
```

```
SELECT 'fat & cow'::tsquery @@ 'a fat cat sat on a mat and ate a fat rat'::tsvector;
?column?
```

```
-----
f
```

As the above example suggests, a `tsquery` is not just raw text, any more than a `tsvector` is. A `tsquery` contains search terms, which must be already-normalized lexemes, and may combine multiple terms using AND, OR, and NOT operators. (For details see Section 8.11.) There are functions `to_tsquery` and `plainto_tsquery` that are helpful in converting user-written text into a proper `tsquery`, for example by normalizing words appearing in the text. Similarly, `to_tsvector` is used to parse and normalize a document string. So in practice a text search match would look more like this:

```
SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat');
?column?
```

```
-----
t
```

Observe that this match would not succeed if written as

```
SELECT 'fat cats ate fat rats'::tsvector @@ to_tsquery('fat & rat');
```

```
?column?
-----
f
```

since here no normalization of the word `rats` will occur. The elements of a `tsvector` are lexemes, which are assumed already normalized, so `rats` does not match `rat`.

The `@@` operator also supports `text` input, allowing explicit conversion of a text string to `tsvector` or `tsquery` to be skipped in simple cases. The variants available are:

```
tsvector @@ tsquery
tsquery  @@ tsvector
text     @@ tsquery
text     @@ text
```

The first two of these we saw already. The form `text @@ tsquery` is equivalent to `to_tsvector(x) @@ y`. The form `text @@ text` is equivalent to `to_tsvector(x) @@ plainto_tsquery(y)`.

### 12.1.3. Configurations

The above are all simple text search examples. As mentioned before, full text search functionality includes the ability to do many more things: skip indexing certain words (stop words), process synonyms, and use sophisticated parsing, e.g. parse based on more than just white space. This functionality is controlled by *text search configurations*. PostgreSQL comes with predefined configurations for many languages, and you can easily create your own configurations. (psql's `\df` command shows all available configurations.)

During installation an appropriate configuration is selected and `default_text_search_config` is set accordingly in `postgresql.conf`. If you are using the same text search configuration for the entire cluster you can use the value in `postgresql.conf`. To use different configurations throughout the cluster but the same configuration within any one database, use `ALTER DATABASE ... SET`. Otherwise, you can set `default_text_search_config` in each session.

Each text search function that depends on a configuration has an optional `regconfig` argument, so that the configuration to use can be specified explicitly. `default_text_search_config` is used only when this argument is omitted.

To make it easier to build custom text search configurations, a configuration is built up from simpler database objects. PostgreSQL's text search facility provides four types of configuration-related database objects:

- *Text search parsers* break documents into tokens and classify each token (for example, as words or numbers).
- *Text search dictionaries* convert tokens to normalized form and reject stop words.
- *Text search templates* provide the functions underlying dictionaries. (A dictionary simply specifies a template and a set of parameters for the template.)
- *Text search configurations* select a parser and a set of dictionaries to use to normalize the tokens produced by the parser.

Text search parsers and templates are built from low-level C functions; therefore it requires C programming ability to develop new ones, and superuser privileges to install one into a database. (There are examples of add-on parsers and templates in the `contrib/` area of the PostgreSQL distribution.) Since dictionaries and configurations just parameterize and connect together some underlying parsers and templates, no special privilege is needed to create a new dictionary or configuration. Examples of creating custom dictionaries and configurations appear later in this chapter.

## 12.2. Tables and Indexes

The examples in the previous section illustrated full text matching using simple constant strings. This section shows how to search table data, optionally using indexes.

### 12.2.1. Searching a Table

It is possible to do full text search with no index. A simple query to print the `title` of each row that contains the word `friend` in its `body` field is:

```
SELECT title
FROM pgweb
WHERE to_tsvector('english', body) @@ to_tsquery('english', 'friend');
```

This will also find related words such as `friends` and `friendly`, since all these are reduced to the same normalized lexeme.

The query above specifies that the `english` configuration is to be used to parse and normalize the strings. Alternatively we could omit the configuration parameters:

```
SELECT title
FROM pgweb
WHERE to_tsvector(body) @@ to_tsquery('friend');
```

This query will use the configuration set by `default_text_search_config`.

A more complex example is to select the ten most recent documents that contain `create` and `table` in the `title` or `body`:

```
SELECT title
FROM pgweb
WHERE to_tsvector(title || body) @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC LIMIT 10;
```

For clarity we omitted the `coalesce` function which would be needed to search rows that contain `NULL` in one of the two fields.

Although these queries will work without an index, most applications will find this approach too slow, except perhaps for occasional ad-hoc searches. Practical use of text searching usually requires creating an index.

### 12.2.2. Creating Indexes

We can create a GIN index (Section 12.9) to speed up text searches:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', body));
```

Notice that the 2-argument version of `to_tsvector` is used. Only text search functions that specify a configuration name can be used in expression indexes (Section 11.7). This is because the index contents must be unaffected by `default_text_search_config`. If they were affected, the index contents might be inconsistent because different entries could contain `tsvector`s that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the two-argument version of `to_tsvector` was used in the index above, only a query reference that uses the 2-argument version of `to_tsvector` with the same configuration name will use that index. That is, `WHERE to_tsvector('english', body) @@ 'a & b'` can use the index, but `WHERE`

`to_tsvector(body) @@ 'a & b'` cannot. This ensures that an index will be used only with the same configuration used to create the index entries.

It is possible to set up more complex expression indexes wherein the configuration name is specified by another column, e.g.:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector(config_name, body));
```

where `config_name` is a column in the `pgweb` table. This allows mixed configurations in the same index while recording which configuration was used for each index entry. This would be useful, for example, if the document collection contained documents in different languages. Again, queries that are to use the index must be phrased to match, e.g. `WHERE to_tsvector(config_name, body) @@ 'a & b'`.

Indexes can even concatenate columns:

```
CREATE INDEX pgweb_idx ON pgweb USING gin(to_tsvector('english', title || body));
```

Another approach is to create a separate `tsvector` column to hold the output of `to_tsvector`. This example is a concatenation of `title` and `body`, using `coalesce` to ensure that one field will still be indexed when the other is `NULL`:

```
ALTER TABLE pgweb ADD COLUMN textsearchable_index_col tsvector;
UPDATE pgweb SET textsearchable_index_col =
    to_tsvector('english', coalesce(title, "") || coalesce(body, ""));
```

Then we create a GIN index to speed up the search:

```
CREATE INDEX textsearch_idx ON pgweb USING gin(textsearchable_index_col);
```

Now we are ready to perform a fast full text search:

```
SELECT title
FROM pgweb
WHERE textsearchable_index_col @@ to_tsquery('create & table')
ORDER BY last_mod_date DESC LIMIT 10;
```

When using a separate column to store the `tsvector` representation, it is necessary to create a trigger to keep the `tsvector` column current anytime `title` or `body` changes. Section 12.4.3 explains how to do that.

One advantage of the separate-column approach over an expression index is that it is not necessary to explicitly specify the text search configuration in queries in order to make use of the index. As shown in the example above, the query can depend on `default_text_search_config`. Another advantage is that searches will be faster, since it will not be necessary to redo the `to_tsvector` calls to verify index matches. (This is more important when using a GiST index than a GIN index; see Section 12.9.) The expression-index approach is simpler to set up, however, and it requires less disk space since the `tsvector` representation is not stored explicitly.

## 12.3. Controlling Text Search

To implement full text searching there must be a function to create a `tsvector` from a document and a `tsquery` from a user query. Also, we need to return results in a useful order, so we need a function that compares documents with respect to their relevance to the query. It's also important to be able to display the results nicely. PostgreSQL provides support for all of these functions.

### 12.3.1. Parsing Documents

PostgreSQL provides the function `to_tsvector` for converting a document to the `tsvector` data type.

```
to_tsvector([ config regconfig, ] document text) returns tsvector
```

`to_tsvector` parses a textual document into tokens, reduces the tokens to lexemes, and returns a `tsvector` which lists the lexemes together with their positions in the document. The document is processed according to the specified or default text search configuration. Here is a simple example:

```
SELECT to_tsvector('english', 'a fat  cat sat on a mat - it ate a fat rats');
           to_tsvector
-----
'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```

In the example above we see that the resulting `tsvector` does not contain the words `a`, `on`, or `it`, the word `rats` became `rat`, and the punctuation sign `-` was ignored.

The `to_tsvector` function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries (Section 12.6) is consulted, where the list can vary depending on the token type. The first dictionary that *recognizes* the token emits one or more normalized *lexemes* to represent the token. For example, `rats` became `rat` because one of the dictionaries recognized that the word `rats` is a plural form of `rat`. Some words are recognized as *stop words* (Section 12.6.1), which causes them to be ignored since they occur too frequently to be useful in searching. In our example these are `a`, `on`, and `it`. If no dictionary in the list recognizes the token then it is also ignored. In this example that happened to the punctuation sign `-` because there are in fact no dictionaries assigned for its token type (`Space symbols`), meaning space tokens will never be indexed. The choices of parser, dictionaries and which types of tokens to index are determined by the selected text search configuration (Section 12.7). It is possible to have many different configurations in the same database, and predefined configurations are available for various languages. In our example we used the default configuration `english` for the English language.

The function `setweight` can be used to label the entries of a `tsvector` with a given *weight*, where a weight is one of the letters A, B, C, or D. This is typically used to mark entries coming from different parts of a document, such as title versus body. Later, this information can be used for ranking of search results.

Because `to_tsvector(NULL)` will return `NULL`, it is recommended to use `coalesce` whenever a field might be null. Here is the recommended method for creating a `tsvector` from a structured document:

```
UPDATE tt SET ti =
    setweight(to_tsvector(coalesce(title,"")), 'A') ||
    setweight(to_tsvector(coalesce(keyword,"")), 'B') ||
```

```
setweight(to_tsvector(coalesce(abstract,"")), 'C') ||
setweight(to_tsvector(coalesce(body,"")), 'D');
```

Here we have used `setweight` to label the source of each lexeme in the finished `tsvector`, and then merged the labeled `tsvector` values using the `tsvector` concatenation operator `||`. (Section 12.4.1 gives details about these operations.)

### 12.3.2. Parsing Queries

PostgreSQL provides the functions `to_tsquery` and `plainto_tsquery` for converting a query to the `tsquery` data type. `to_tsquery` offers access to more features than `plainto_tsquery`, but is less forgiving about its input.

```
to_tsquery([ config regconfig, ] querytext text) returns tsquery
```

`to_tsquery` creates a `tsquery` value from `querytext`, which must consist of single tokens separated by the Boolean operators `&` (AND), `|` (OR) and `!` (NOT). These operators can be grouped using parentheses. In other words, the input to `to_tsquery` must already follow the general rules for `tsquery` input, as described in Section 8.11. The difference is that while basic `tsquery` input takes the tokens at face value, `to_tsquery` normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```
SELECT to_tsquery('english', 'The & Fat & Rats');
       to_tsquery
-----
'fat' & 'rat'
```

As in basic `tsquery` input, weight(s) can be attached to each lexeme to restrict it to match only `tsvector` lexemes of those weight(s). For example:

```
SELECT to_tsquery('english', 'Fat | Rats:AB');
       to_tsquery
-----
'fat' | 'rat':AB
```

`to_tsquery` can also accept single-quoted phrases. This is primarily useful when the configuration includes a thesaurus dictionary that may trigger on such phrases. In the example below, a thesaurus contains the rule `supernovae stars : sn:`

```
SELECT to_tsquery('supernovae stars' & !crab');
       to_tsquery
-----
'sn' & !'crab'
```

Without quotes, `to_tsquery` will generate a syntax error for tokens that are not separated by an AND or OR operator.

```
plainto_tsquery([ config regconfig, ] querytext text) returns tsquery
```

`plainto_tsquery` transforms unformatted text *querytext* to *tsquery*. The text is parsed and normalized much as for `to_tsvector`, then the `&` (AND) Boolean operator is inserted between surviving words.

Example:

```
SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery
-----
'fat' & 'rat'
```

Note that `plainto_tsquery` cannot recognize either Boolean operators or weight labels in its input:

```
SELECT plainto_tsquery('english', 'The Fat & Rats:C');
plainto_tsquery
-----
'fat' & 'rat' & 'c'
```

Here, all the input punctuation was discarded as being space symbols.

### 12.3.3. Ranking Search Results

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. PostgreSQL provides two predefined ranking functions, which take into account lexical, proximity, and structural information; that is, they consider how often the query terms appear in the document, how close together the terms are in the document, and how important is the part of the document where they occur. However, the concept of relevancy is vague and very application-specific. Different applications might require additional information for ranking, e.g. document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:

```
ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])
```

Standard ranking function.

```
ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])
```

This function computes the *cover density* ranking for the given document vector and query, as described in Clarke, Cormack, and Tudhope's "Relevance Ranking for One to Three Term Queries" in the journal "Information Processing and Management", 1999.

This function requires positional information in its input. Therefore it will not work on "stripped" `tsvector` values — it will always return zero.

For both these functions, the optional *weights* argument offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of word, in the order:

```
{D-weight, C-weight, B-weight, A-weight}
```

If no *weights* are provided, then these defaults are used:

```
{0.1, 0.2, 0.4, 1.0}
```

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so that they can be treated as more or less important than words in the document body.

Since a longer document has a greater chance of containing a query term it is reasonable to take into account document size, e.g. a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer *normalization* option that specifies whether and how a document's length should impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using `|` (for example, `2|4`).

- 0 (the default) ignores the document length
- 1 divides the rank by  $1 + \text{the logarithm of the document length}$
- 2 divides the rank by the document length
- 4 divides the rank by the mean harmonic distance between extents (this is implemented only by `ts_rank_cd`)
- 8 divides the rank by the number of unique words in document
- 16 divides the rank by  $1 + \text{the logarithm of the number of unique words in document}$
- 32 divides the rank by itself + 1

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option 32 ( $\text{rank}/(\text{rank}+1)$ ) can be applied to scale all ranks into the range zero to one, but of course this is just a cosmetic change; it will not affect the ordering of the search results.

Here is an example that selects only the ten highest-ranked matches:

```
SELECT title, ts_rank_cd(textsearch, query) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC LIMIT 10;
```

title	rank
Neutrinos in the Sun	3.1
The Sudbury Neutrino Detector	2.4
A MACHO View of Galactic Dark Matter	2.01317
Hot Gas and Dark Matter	1.91171
The Virgo Cluster: Hot Plasma and Dark Matter	1.90953
Rafting for Solar Neutrinos	1.9
NGC 4650A: Strange Galaxy and Dark Matter	1.85774
Hot Gas and Dark Matter	1.6123
Ice Fishing for Cosmic Neutrinos	1.6
Weak Lensing Distorts the Universe	0.818218

This is the same example using normalized ranking:

```
SELECT title, ts_rank_cd(textsearch, query, 32 /* rank/(rank+1) */ ) AS rank
FROM apod, to_tsquery('neutrino|(dark & matter)') query
WHERE query @@ textsearch
ORDER BY rank DESC LIMIT 10;
```

title	rank
Neutrinos in the Sun	0.756097569485493
The Sudbury Neutrino Detector	0.705882361190954
A MACHO View of Galactic Dark Matter	0.668123210574724
Hot Gas and Dark Matter	0.65655958650282
The Virgo Cluster: Hot Plasma and Dark Matter	0.656301290640973
Rafting for Solar Neutrinos	0.655172410958162
NGC 4650A: Strange Galaxy and Dark Matter	0.650072921219637
Hot Gas and Dark Matter	0.617195790024749
Ice Fishing for Cosmic Neutrinos	0.615384618911517
Weak Lensing Distorts the Universe	0.450010798361481

Ranking can be expensive since it requires consulting the `tsvector` of each matching document, which can be I/O bound and therefore slow. Unfortunately, it is almost impossible to avoid since practical queries often result in large numbers of matches.

### 12.3.4. Highlighting Results

To present search results it is ideal to show a part of each document and how it is related to the query. Usually, search engines show fragments of the document with marked search terms. PostgreSQL provides a function `ts_headline` that implements this functionality.

```
ts_headline([ config regconfig, ] document text, query tsquery [, options text ]) returns text
```

`ts_headline` accepts a document along with a query, and returns an excerpt from the document in which terms from the query are highlighted. The configuration to be used to parse the document can be specified by `config`; if `config` is omitted, the `default_text_search_config` configuration is used.

If an `options` string is specified it must consist of a comma-separated list of one or more `option=value` pairs. The available options are:

- `StartSel`, `StopSel`: the strings with which query words appearing in the document should be delimited to distinguish them from other excerpted words.
- `MaxWords`, `MinWords`: these numbers determine the longest and shortest headlines to output.
- `ShortWord`: words of this length or less will be dropped at the start and end of a headline. The default value of three eliminates the English articles.
- `HighlightAll`: Boolean flag; if `true` the whole document will be highlighted.

Any unspecified options receive these defaults:

```
StartSel=<b>, StopSel=</b>, MaxWords=35, MinWords=15, ShortWord=3, HighlightAll=FALSE
```

For example:

```
SELECT ts_headline('english', 'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.', to_tsquery('query & similarity'));
        ts_headline
```

```
-----
given <b>query</b> terms
and return them in order of their <b>similarity</b> to the
<b>query</b>.
```

```
SELECT ts_headline('english', 'The most common type of search
is to find all documents containing given query terms
and return them in order of their similarity to the
query.',
        to_tsquery('query & similarity'),
        'StartSel = <, StopSel = >');
        ts_headline
```

```
-----
given <query> terms
and return them in order of their <similarity> to the
<query>.
```

`ts_headline` uses the original document, not a `tsvector` summary, so it can be slow and should be used with care. A typical mistake is to call `ts_headline` for *every* matching document when only ten documents are to be shown. SQL subqueries can help; here is an example:

```
SELECT id, ts_headline(body, q), rank
FROM (SELECT id, body, q, ts_rank_cd(ti, q) AS rank
      FROM apod, to_tsquery('stars') q
      WHERE ti @@ q
      ORDER BY rank DESC LIMIT 10) AS foo;
```

## 12.4. Additional Features

This section describes additional functions and operators that are useful in connection with text search.

### 12.4.1. Manipulating Documents

Section 12.3.1 showed how raw textual documents can be converted into `tsvector` values. PostgreSQL also provides functions and operators that can be used to manipulate documents that are already in `tsvector` form.

```
tsvector || tsvector
```

The `tsvector` concatenation operator returns a vector which combines the lexemes and positional information of the two vectors given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand vector are offset by the largest position mentioned in the left-hand vector, so that the result is nearly equivalent to the result of performing `to_tsvector` on the concatenation of the two original document strings. (The equivalence is not exact, because any stop-words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

One advantage of using concatenation in the vector form, rather than concatenating text before applying `to_tsvector`, is that you can use different configurations to parse different sections of the document. Also, because the `setweight` function marks all lexemes of the given vector the same way, it is necessary to parse the text and do `setweight` before concatenating if you want to label different parts of the document with different weights.

```
setweight(vector tsvector, weight "char") returns tsvector
```

This function returns a copy of the input vector in which every position has been labeled with the given *weight*, either A, B, C, or D. (D is the default for new vectors and as such is not displayed on output.) These labels are retained when vectors are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.

Note that weight labels apply to *positions*, not *lexemes*. If the input vector has been stripped of positions then `setweight` does nothing.

```
length(vector tsvector) returns integer
```

Returns the number of lexemes stored in the vector.

```
strip(vector tsvector) returns tsvector
```

Returns a vector which lists the same lexemes as the given vector, but which lacks any position or weight information. While the returned vector is much less useful than an unstripped vector for relevance ranking, it will usually be much smaller.

## 12.4.2. Manipulating Queries

Section 12.3.2 showed how raw textual queries can be converted into `tsquery` values. PostgreSQL also provides functions and operators that can be used to manipulate queries that are already in `tsquery` form.

```
tsquery && tsquery
```

Returns the AND-combination of the two given queries.

```
tsquery || tsquery
```

Returns the OR-combination of the two given queries.

```
!! tsquery
```

Returns the negation (NOT) of the given query.

```
numnode(query tsquery) returns integer
```

Returns the number of nodes (lexemes plus operators) in a `tsquery`. This function is useful to determine if the `query` is meaningful (returns > 0), or contains only stop words (returns 0). Examples:

```
SELECT numnode(plainto_tsquery('the any'));
NOTICE: query contains only stopwords or doesn't contain lexeme(s), ignored
numnode
-----
      0

SELECT numnode('foo & bar'::tsquery);
numnode
-----
      3
```

```
querytree(query tsquery) returns text
```

Returns the portion of a `tsquery` that can be used for searching an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms.

For example:

```
SELECT querytree(to_tsquery('!defined'));
querytree
-----
```

### 12.4.2.1. Query Rewriting

The `ts_rewrite` family of functions search a given `tsquery` for occurrences of a target subquery, and replace each occurrence with another substitute subquery. In essence this operation is a `tsquery`-specific version of substring replacement. A target and substitute combination can be thought of as a *query rewrite rule*. A collection of such rewrite rules can be a powerful search aid. For example, you can expand the search using synonyms (e.g., `new york`, `big apple`, `nyc`, `gotham`) or narrow the search to direct the user to some hot topic. There is some overlap in functionality between this feature and thesaurus dictionaries (Section 12.6.4). However, you can modify a set of rewrite rules on-the-fly without reindexing, whereas updating a thesaurus requires reindexing to be effective.

```
ts_rewrite (query tsquery, target tsquery, substitute tsquery) returns tsquery
```

This form of `ts_rewrite` simply applies a single rewrite rule: *target* is replaced by *substitute* wherever it appears in *query*. For example:

```
SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'c'::tsquery);
      ts_rewrite
-----
' b' & ' c'

      ts_rewrite (query tsquery, select text) returns tsquery
```

This form of `ts_rewrite` accepts a starting *query* and a SQL *select* command, which is given as a text string. The *select* must yield two columns of `tsquery` type. For each row of the *select* result, occurrences of the first column value (the target) are replaced by the second column value (the substitute) within the current *query* value. For example:

```
CREATE TABLE aliases (t tsquery PRIMARY KEY, s tsquery);
INSERT INTO aliases VALUES('a', 'c');

SELECT ts_rewrite('a & b'::tsquery, 'SELECT t,s FROM aliases');
      ts_rewrite
-----
' b' & ' c'
```

Note that when multiple rewrite rules are applied in this way, the order of application can be important; so in practice you will want the source query to `ORDER BY` some ordering key.

Let's consider a real-life astronomical example. We'll expand query `supernovae` using table-driven rewriting rules:

```
CREATE TABLE aliases (t tsquery primary key, s tsquery);
INSERT INTO aliases VALUES(to_tsquery('supernovae'), to_tsquery('supernovae|sn'));

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT * FROM aliases');
      ts_rewrite
-----
'crab' & ( 'supernova' | 'sn' )
```

We can change the rewriting rules just by updating the table:

```
UPDATE aliases SET s = to_tsquery('supernovae|sn & !nebulae') WHERE t = to_tsquery('supernovae & crab');

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT * FROM aliases');
      ts_rewrite
-----
'crab' & ( 'supernova' | 'sn' & !'nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible hit. To filter out obvious non-candidate rules we can use the containment operators for the `tsquery` type. In the example below, we select only those rules which might match the original query:

```
SELECT ts_rewrite('a & b'::tsquery,
```

```

                                'SELECT t,s FROM aliases WHERE "a & b"::tsquery @> t');
ts_rewrite
-----
'b' & 'c'

```

### 12.4.3. Triggers for Automatic Updates

When using a separate column to store the `tsvector` representation of your documents, it is necessary to create a trigger to update the `tsvector` column when the document content columns change. Two built-in trigger functions are available for this, or you can write your own.

```

tsvector_update_trigger(tsvector_column_name, config_name, text_column_name [, ... ])
tsvector_update_trigger_column(tsvector_column_name, config_column_name, text_column_name [,

```

These trigger functions automatically compute a `tsvector` column from one or more textual columns, under the control of parameters specified in the `CREATE TRIGGER` command. An example of their use is:

```

CREATE TABLE messages (
    title      text,
    body       text,
    tsv        tsvector
);

CREATE TRIGGER tsvectorupdate BEFORE INSERT OR UPDATE
ON messages FOR EACH ROW EXECUTE PROCEDURE
tsvector_update_trigger(tsv, 'pg_catalog.english', title, body);

INSERT INTO messages VALUES('title here', 'the body text is here');

SELECT * FROM messages;
 title      |          body          |          tsv
-----+-----+-----
 title here | the body text is here | 'bodi':4 'text':5 'titl':1

SELECT title, body FROM messages WHERE tsv @@ to_tsquery('title & body');
 title      |          body
-----+-----
 title here | the body text is here

```

Having created this trigger, any change in `title` or `body` will automatically be reflected into `tsv`, without the application having to worry about it.

The first trigger argument must be the name of the `tsvector` column to be updated. The second argument specifies the text search configuration to be used to perform the conversion. For `tsvector_update_trigger`, the configuration name is simply given as the second trigger argument. It must be schema-qualified as shown above, so that the trigger behavior will not change with changes in `search_path`. For `tsvector_update_trigger_column`, the second trigger argument is the

name of another table column, which must be of type `regconfig`. This allows a per-row selection of configuration to be made. The remaining argument(s) are the names of textual columns (of type `text`, `varchar`, or `char`). These will be included in the document in the order given. NULL values will be skipped (but the other columns will still be indexed).

A limitation of the built-in triggers is that they treat all the input columns alike. To process columns differently — for example, to weight title differently from body — it is necessary to write a custom trigger. Here is an example using PL/pgSQL as the trigger language:

```
CREATE FUNCTION messages_trigger() RETURNS trigger AS $$
begin
    new.tsv :=
        setweight(to_tsvector('pg_catalog.english', coalesce(new.title,"")), 'A') ||
        setweight(to_tsvector('pg_catalog.english', coalesce(new.body,"")), 'D');
    return new;
end
$$ LANGUAGE plpgsql;

CREATE TRIGGER tsvectorupdate BEFORE INSERT OR UPDATE
ON messages FOR EACH ROW EXECUTE PROCEDURE messages_trigger();
```

Keep in mind that it is important to specify the configuration name explicitly when creating `tsvector` values inside triggers, so that the column's contents will not be affected by changes to `default_text_search_config`. Failure to do this is likely to lead to problems such as search results changing after a dump and reload.

## 12.4.4. Gathering Document Statistics

The function `ts_stat` is useful for checking your configuration and for finding stop-word candidates.

```
ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndoc integer, OUT nentry integer)
```

`sqlquery` is a text value containing a SQL query which must return a single `tsvector` column. `ts_stat` executes the query and returns statistics about each distinct lexeme (word) contained in the `tsvector` data. The columns returned are

- `word text` — the value of a lexeme
- `ndoc integer` — number of documents (`tsvectors`) the word occurred in
- `nentry integer` — total number of occurrences of the word

If `weights` is supplied, only occurrences having one of those weights are counted.

For example, to find the ten most frequent words in a document collection:

```
SELECT * FROM ts_stat('SELECT vector FROM apod')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

The same, but counting only word occurrences with weight A or B:

```
SELECT * FROM ts_stat('SELECT vector FROM apod', 'ab')
ORDER BY nentry DESC, ndoc DESC, word
LIMIT 10;
```

## 12.5. Parsers

Text search parsers are responsible for splitting raw document text into *tokens* and identifying each token's type, where the set of possible types is defined by the parser itself. Note that a parser does not modify the text at all — it simply identifies plausible word boundaries. Because of this limited scope, there is less need for application-specific custom parsers than there is for custom dictionaries. At present PostgreSQL provides just one built-in parser, which has been found to be useful for a wide range of applications.

The built-in parser is named `pg_catalog.default`. It recognizes 23 token types:

**Table 12-1. Default Parser's Token Types**

Alias	Description	Example
<code>asciiword</code>	Word, all ASCII letters	elephant
<code>word</code>	Word, all letters	mañana
<code>numword</code>	Word, letters and digits	beta1
<code>asciihword</code>	Hyphenated word, all ASCII	up-to-date
<code>hword</code>	Hyphenated word, all letters	lógico-matemática
<code>numhword</code>	Hyphenated word, letters and digits	postgresql-beta1
<code>hword_asciipart</code>	Hyphenated word part, all ASCII	postgresql in the context postgresql-beta1
<code>hword_part</code>	Hyphenated word part, all letters	lógico or matemática in the context lógico-matemática
<code>hword_numpart</code>	Hyphenated word part, letters and digits	beta1 in the context postgresql-beta1
<code>email</code>	Email address	foo@example.com
<code>protocol</code>	Protocol head	http://
<code>url</code>	URL	example.com/stuff/index.html
<code>host</code>	Host	example.com
<code>url_path</code>	URL path	/stuff/index.html, in the context of a URL
<code>file</code>	File or path name	/usr/local/foo.txt, if not within a URL

Alias	Description	Example
sfloat	Scientific notation	-1.234e56
float	Decimal notation	-1.234
int	Signed integer	-1234
uint	Unsigned integer	1234
version	Version number	8.3.0
tag	XML tag	<a href="dictionaries.html">
entity	XML entity	&amp;
blank	Space symbols	(any whitespace or punctuation not otherwise recognized)

**Note:** The parser's notion of a "letter" is determined by the server's locale setting, specifically `lc_ctype`. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types `word` and `asciiword` should always be treated alike.

It is possible for the parser to produce overlapping tokens from the same piece of text. As an example, a hyphenated word will be reported both as the entire word and as each component:

```
SELECT alias, description, token FROM ts_debug('foo-bar-betal');
```

alias	description	token
numhword	Hyphenated word, letters and digits	foo-bar-betal
hword_asciipart	Hyphenated word part, all ASCII	foo
blank	Space symbols	-
hword_asciipart	Hyphenated word part, all ASCII	bar
blank	Space symbols	-
hword_numpart	Hyphenated word part, letters and digits	betal

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another instructive example:

```
SELECT alias, description, token FROM ts_debug('http://example.com/stuff/index.html');
```

alias	description	token
protocol	Protocol head	http://
url	URL	example.com/stuff/index.html
host	Host	example.com
url_path	URL path	/stuff/index.html

## 12.6. Dictionaries

Dictionaries are used to eliminate words that should not be considered in a search (*stop words*), and to *normalize* words so that different derived forms of the same word will match. A successfully normalized word is called a *lexeme*. Aside from improving search quality, normalization and removal of stop words reduce the size of the `tsvector` representation of a document, thereby improving performance. Normalization does not always have linguistic meaning and usually depends on application semantics.

Some examples of normalization:

- Linguistic - Ispell dictionaries try to reduce input words to a normalized form; stemmer dictionaries remove word endings
- URL locations can be canonicalized to make equivalent URLs match:
  - `http://www.pgsql.ru/db/mw/index.html`
  - `http://www.pgsql.ru/db/mw/`
  - `http://www.pgsql.ru/db/./db/mw/index.html`
- Color names can be replaced by their hexadecimal values, e.g., `red`, `green`, `blue`, `magenta` -> `FF0000`, `00FF00`, `0000FF`, `FF00FF`
- If indexing numbers, we can remove some fractional digits to reduce the range of possible numbers, so for example `3.14159265359`, `3.1415926`, `3.14` will be the same after normalization if only two digits are kept after the decimal point.

A dictionary is a program that accepts a token as input and returns:

- an array of lexemes if the input token is known to the dictionary (notice that one token can produce more than one lexeme)
- an empty array if the dictionary knows the token, but it is a stop word
- `NULL` if the dictionary does not recognize the input token

PostgreSQL provides predefined dictionaries for many languages. There are also several predefined templates that can be used to create new dictionaries with custom parameters. Each predefined dictionary template is described below. If no existing template is suitable, it is possible to create new ones; see the `contrib/` area of the PostgreSQL distribution for examples.

A text search configuration binds a parser together with a set of dictionaries to process the parser's output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until some dictionary recognizes it as a known word. If it is identified as a stop word, or if no dictionary recognizes the token, it will be discarded and not indexed or searched for. The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing with a very general dictionary, like a Snowball stemmer or `simple`, which recognizes everything. For example, for an astronomy-specific search (`astro_en` configuration) one could bind token type `asciiword` (ASCII word) to a synonym dictionary of astronomical terms, a general English dictionary and a Snowball English stemmer:

```
ALTER TEXT SEARCH CONFIGURATION astro_en
  ADD MAPPING FOR asciiword WITH astrosyn, english_ispell, english_stem;
```

### 12.6.1. Stop Words

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full text searching. For example, every English text contains words like `a` and `the`, so it is useless to store them in an index. However, stop words do affect the positions in `tsvector`, which in turn affect ranking:

```
SELECT to_tsvector('english','in the list of stop words');
           to_tsvector
-----
 'list':3 'stop':5 'word':6
```

The missing positions 1,2,4 are because of stop words. Ranks calculated for documents with and without stop words are quite different:

```
SELECT ts_rank_cd (to_tsvector('english','in the list of stop words'), to_tsquery('list & s
ts_rank_cd
-----
          0.05

SELECT ts_rank_cd (to_tsvector('english','list stop words'), to_tsquery('list & stop'));
ts_rank_cd
-----
          0.1
```

It is up to the specific dictionary how it treats stop words. For example, `ispell` dictionaries first normalize words and then look at the list of stop words, while `snowball` stemmers first check the list of stop words. The reason for the different behavior is an attempt to decrease noise.

### 12.6.2. Simple Dictionary

The `simple` dictionary template operates by converting the input token to lower case and checking it against a file of stop words. If it is found in the file then an empty array is returned, causing the token to be discarded. If not, the lower-cased form of the word is returned as the normalized lexeme. Alternatively, the dictionary can be configured to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Here is an example of a dictionary definition using the `simple` template:

```
CREATE TEXT SEARCH DICTIONARY public.simple_dict (
    TEMPLATE = pg_catalog.simple,
    STOPWORDS = english
);
```

Here, `english` is the base name of a file of stop words. The file's full name will be `$SHAREDIR/tsearch_data/english.stop`, where `$SHAREDIR` means the PostgreSQL installation's

shared-data directory, often `/usr/local/share/postgresql` (use `pg_config --sharedir` to determine it if you're not sure). The file format is simply a list of words, one per line. Blank lines and trailing spaces are ignored, and upper case is folded to lower case, but no other processing is done on the file contents.

Now we can test our dictionary:

```
SELECT ts_lexize('public.simple_dict','Yes');
ts_lexize
-----
{yes}

SELECT ts_lexize('public.simple_dict','The');
ts_lexize
-----
{ }
```

We can also choose to return `NULL`, instead of the lower-cased word, if it is not found in the stop words file. This behavior is selected by setting the dictionary's `Accept` parameter to `false`. Continuing the example:

```
ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );

SELECT ts_lexize('public.simple_dict','Yes');
ts_lexize
-----

SELECT ts_lexize('public.simple_dict','The');
ts_lexize
-----
{ }
```

With the default setting of `Accept = true`, it is only useful to place a `simple` dictionary at the end of a list of dictionaries, since it will never pass on any token to a following dictionary. Conversely, `Accept = false` is only useful when there is at least one following dictionary.

### Caution

Most types of dictionaries rely on configuration files, such as files of stop words. These files *must* be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.

### Caution

Normally, a database session will read a dictionary configuration file only once, when it is first used within the session. If you modify a configuration file and want to force existing sessions to pick up the new contents, issue an `ALTER TEXT SEARCH DICTIONARY` command on the dictionary. This can be a “dummy” update that doesn’t actually change any parameter values.

## 12.6.3. Synonym Dictionary

This dictionary template is used to create dictionaries that replace a word with a synonym. Phrases are not supported (use the thesaurus template (Section 12.6.4) for that). A synonym dictionary can be used to overcome linguistic problems, for example, to prevent an English stemmer dictionary from reducing the word ‘Paris’ to ‘pari’. It is enough to have a `Paris pari` line in the synonym dictionary and put it before the `english_stem` dictionary:

```
SELECT * FROM ts_debug('english', 'Paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {english_stem} | english_stem | {pari}

CREATE TEXT SEARCH DICTIONARY my_synonym (
    TEMPLATE = synonym,
    SYNONYMS = my_synonyms
);

ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR asciiword WITH my_synonym, english_stem;

SELECT * FROM ts_debug('english', 'Paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {paris}
```

The only parameter required by the `synonym` template is `SYNONYMS`, which is the base name of its configuration file — `my_synonyms` in the above example. The file’s full name will be `$$SHAREDIR/tsearch_data/my_synonyms.syn` (where `$$SHAREDIR` means the PostgreSQL installation’s shared-data directory). The file format is just one line per word to be substituted, with the word followed by its synonym, separated by white space. Blank lines and trailing spaces are ignored, and upper case is folded to lower case.

## 12.6.4. Thesaurus Dictionary

A thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that includes information about the relationships of words and phrases, i.e., broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, related terms, etc.

Basically a thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well. PostgreSQL's current implementation of the thesaurus dictionary is an extension of the synonym dictionary with added *phrase* support. A thesaurus dictionary requires a configuration file of the following format:

```
# this is a comment
sample word(s) : indexed word(s)
more sample word(s) : more indexed word(s)
...
```

where the colon (:) symbol acts as a delimiter between a phrase and its replacement.

A thesaurus dictionary uses a *subdictionary* (which is specified in the dictionary's configuration) to normalize the input text before checking for phrase matches. It is only possible to select one subsdictionary. An error is reported if the subsdictionary fails to recognize a word. In that case, you should remove the use of the word or teach the subsdictionary about it. You can place an asterisk (\*) at the beginning of an indexed word to skip applying the subsdictionary to it, but all sample words *must* be known to the subsdictionary.

The thesaurus dictionary chooses the longest match if there are multiple phrases matching the input, and ties are broken by using the last definition.

Specific stop words recognized by the subsdictionary cannot be specified; instead use ? to mark the location where any stop word can appear. For example, assuming that a and the are stop words according to the subsdictionary:

```
? one ? two : ssws
```

matches a one the two and the one a two; both would be replaced by ssws.

Since a thesaurus dictionary has the capability to recognize phrases it must remember its state and interact with the parser. A thesaurus dictionary uses these assignments to check if it should handle the next word or stop accumulation. The thesaurus dictionary must be configured carefully. For example, if the thesaurus dictionary is assigned to handle only the `asciiword` token, then a thesaurus dictionary definition like `one 7` will not work since token type `uint` is not assigned to the thesaurus dictionary.

### Caution

Thesauruses are used during indexing so any change in the thesaurus dictionary's parameters *requires* reindexing. For most other dictionary types, small changes such as adding or removing stopwords does not force reindexing.

#### 12.6.4.1. Thesaurus Configuration

To define a new thesaurus dictionary, use the `thesaurus` template. For example:

```
CREATE TEXT SEARCH DICTIONARY thesaurus_simple (
    TEMPLATE = thesaurus,
    DictFile = mythesaurus,
    Dictionary = pg_catalog.english_stem
);
```

Here:

- `thesaurus_simple` is the new dictionary's name
- `mythesaurus` is the base name of the thesaurus configuration file. (Its full name will be `$SHAREDIR/tsearch_data/mythesaurus.ths`, where `$SHAREDIR` means the installation shared-data directory.)
- `pg_catalog.english_stem` is the subdictionary (here, a Snowball English stemmer) to use for thesaurus normalization. Notice that the subdictionary will have its own configuration (for example, stop words), which is not shown here.

Now it is possible to bind the thesaurus dictionary `thesaurus_simple` to the desired token types in a configuration, for example:

```
ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart WITH thesaurus_simple;
```

### 12.6.4.2. Thesaurus Example

Consider a simple astronomical thesaurus `thesaurus_astro`, which contains some astronomical word combinations:

```
supernovae stars : sn
crab nebulae : crab
```

Below we create a dictionary and bind some token types to an astronomical thesaurus and English stemmer:

```
CREATE TEXT SEARCH DICTIONARY thesaurus_astro (
    TEMPLATE = thesaurus,
    DictFile = thesaurus_astro,
    Dictionary = english_stem
);

ALTER TEXT SEARCH CONFIGURATION russian
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart WITH thesaurus_astro, english_
```

Now we can see how it works. `ts_lexize` is not very useful for testing a thesaurus, because it treats its input as a single token. Instead we can use `plainto_tsquery` and `to_tsvector` which will break their input strings into multiple tokens:

```
SELECT plainto_tsquery('supernova star');
plainto_tsquery
-----
'sn'

SELECT to_tsvector('supernova star');
to_tsvector
-----
'sn':1
```

In principle, one can use `to_tsquery` if you quote the argument:

```
SELECT to_tsquery('supernova star');
      to_tsquery
-----
      'sn'
```

Notice that `supernova star` matches `supernovae stars` in `thesaurus_astro` because we specified the `english_stem` stemmer in the `thesaurus` definition. The stemmer removed the `e` and `s`.

To index the original phrase as well as the substitute, just include it in the right-hand part of the definition:

```
supernovae stars : sn supernovae stars

SELECT plainto_tsquery('supernova star');
      plainto_tsquery
-----
      'sn' & 'supernova' & 'star'
```

## 12.6.5. Ispell Dictionary

The Ispell dictionary template supports *morphological dictionaries*, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all declensions and conjugations of the search term `bank`, e.g. `banking`, `banked`, `banks`, `banks'`, and `bank's`.

The standard PostgreSQL distribution does not include any Ispell configuration files. Dictionaries for a large number of languages are available from Ispell<sup>1</sup>. Also, some more modern dictionary file formats are supported — MySpell<sup>2</sup> (OO < 2.0.1) and Hunspell<sup>3</sup> (OO >= 2.0.2). A large list of dictionaries is available on the OpenOffice Wiki<sup>4</sup>.

To create an Ispell dictionary, use the built-in `ispell` template and specify several parameters:

```
CREATE TEXT SEARCH DICTIONARY english_ispell (
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);
```

Here, `DictFile`, `AffFile`, and `StopWords` specify the base names of the dictionary, affixes, and stop-words files. The stop-words file has the same format explained above for the `simple` dictionary type. The format of the other files is not specified here but is available from the above-mentioned web sites.

Ispell dictionaries usually recognize a limited set of words, so they should be followed by another broader dictionary; for example, a Snowball dictionary, which recognizes everything.

1. <http://ficus-www.cs.ucla.edu/geoff/ispell.html>
2. <http://en.wikipedia.org/wiki/MySpell>
3. <http://sourceforge.net/projects/hunspell>
4. <http://wiki.services.openoffice.org/wiki/Dictionaries>

IsPELL dictionaries support splitting compound words. This is a nice feature and PostgreSQL supports it. Notice that the affix file should specify a special flag using the `compoundwords controlled` statement that marks dictionary words that can participate in compound formation:

```
compoundwords controlled z
```

Here are some examples for the Norwegian language:

```
SELECT ts_lexize('norwegian_ispell', 'overbuljongterningpakkmasterassistent');
       {over,buljong,terning,pakk,mester,assistent}
SELECT ts_lexize('norwegian_ispell', 'sjokoladefabrikk');
       {sjokoladefabrikk,sjokolade,fabrikk}
```

**Note:** MySpell does not support compound words. Hunspell has sophisticated support for compound words. At present, PostgreSQL implements only the basic compound word operations of Hunspell.

## 12.6.6. Snowball Dictionary

The Snowball dictionary template is based on the project of Martin Porter, inventor of the popular Porter's stemming algorithm for the English language. Snowball now provides stemming algorithms for many languages (see the Snowball site<sup>5</sup> for more information). Each algorithm understands how to reduce common variant forms of words to a base, or stem, spelling within its language. A Snowball dictionary requires a `language` parameter to identify which stemmer to use, and optionally can specify a `stopword` file name that gives a list of words to eliminate. (PostgreSQL's standard stopwords lists are also provided by the Snowball project.) For example, there is a built-in definition equivalent to

```
CREATE TEXT SEARCH DICTIONARY english_stem (
    TEMPLATE = snowball,
    Language = english,
    StopWords = english
);
```

The stopwords file format is the same as already explained.

A Snowball dictionary recognizes everything, whether or not it is able to simplify the word, so it should be placed at the end of the dictionary list. It is useless to have it before any other dictionary because a token will never pass through it to the next dictionary.

## 12.7. Configuration Example

A text search configuration specifies all options necessary to transform a document into a `tsvector`: the parser to use to break text into tokens, and the dictionaries to use to transform each token into a lexeme.

---

5. <http://snowball.tartarus.org>

Every call of `to_tsvector` or `to_tsquery` needs a text search configuration to perform its processing. The configuration parameter `default_text_search_config` specifies the name of the default configuration, which is the one used by text search functions if an explicit configuration parameter is omitted. It can be set in `postgresql.conf`, or set for an individual session using the `SET` command.

Several predefined text search configurations are available, and you can create custom configurations easily. To facilitate management of text search objects, a set of SQL commands is available, and there are several `psql` commands that display information about text search objects (Section 12.10).

As an example, we will create a configuration `pg`, starting from a duplicate of the built-in `english` configuration.

```
CREATE TEXT SEARCH CONFIGURATION public.pg ( COPY = pg_catalog.english );
```

We will use a PostgreSQL-specific synonym list and store it in `$SHAREDIR/tsearch_data/pg_dict.syn`. The file contents look like:

```
postgres    pg
pgsql       pg
postgresql  pg
```

We define the synonym dictionary like this:

```
CREATE TEXT SEARCH DICTIONARY pg_dict (
    TEMPLATE = synonym,
    SYNONYMS = pg_dict
);
```

Next we register the Ispell dictionary `english_ispell`, which has its own configuration files:

```
CREATE TEXT SEARCH DICTIONARY english_ispell (
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);
```

Now we can set up the mappings for words in configuration `pg`:

```
ALTER TEXT SEARCH CONFIGURATION pg
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                    word, hword, hword_part
    WITH pg_dict, english_ispell, english_stem;
```

We choose not to index or search some token types that the built-in configuration does handle:

```
ALTER TEXT SEARCH CONFIGURATION pg
    DROP MAPPING FOR email, url, url_path, sfloat, float;
```

Now we can test our configuration:

```
SELECT * FROM ts_debug('public.pg', '
PostgreSQL, the highly scalable, SQL compliant, open source object-relational
database management system, is now undergoing beta testing of the next
version of our software.
');
```

The next step is to set the session to use the new configuration, which was created in the `public` schema:

```
=> \dF
      List of text search configurations
 Schema | Name | Description
-----+-----+-----
 public | pg   |

SET default_text_search_config = 'public.pg';
SET

SHOW default_text_search_config;
 default_text_search_config
-----
 public.pg
```

## 12.8. Testing and Debugging Text Search

The behavior of a custom text search configuration can easily become complicated enough to be confusing or undesirable. The functions described in this section are useful for testing text search objects. You can test a complete configuration, or test parsers and dictionaries separately.

### 12.8.1. Configuration Testing

The function `ts_debug` allows easy testing of a text search configuration.

```
ts_debug([ config regconfig, ] document text,
         OUT alias text,
         OUT description text,
         OUT token text,
         OUT dictionaries regdictionary[],
         OUT dictionary regdictionary,
         OUT lexemes text[])
returns setof record
```

`ts_debug` displays information about every token of *document* as produced by the parser and processed by the configured dictionaries. It uses the configuration specified by *config*, or `default_text_search_config` if that argument is omitted.

`ts_debug` returns one row for each token identified in the text by the parser. The columns returned are

- *alias* text — short name of the token type
- *description* text — description of the token type
- *token* text — text of the token
- *dictionaries* regdictionary[] — the dictionaries selected by the configuration for this token type
- *dictionary* regdictionary — the dictionary that recognized the token, or NULL if none did
- *lexemes* text[] — the lexeme(s) produced by the dictionary that recognized the token, or NULL if none did; an empty array ({} ) means it was recognized as a stop word

Here is a simple example:

```
SELECT * FROM ts_debug('english','a fat  cat sat on a mat - it ate a fat rats');
```

alias	description	token	dictionaries	dictionary	lexemes
asciiword	Word, all ASCII	a	{english_stem}	english_stem	{}
blank	Space symbols		{}		
asciiword	Word, all ASCII	fat	{english_stem}	english_stem	{fat}
blank	Space symbols		{}		
asciiword	Word, all ASCII	cat	{english_stem}	english_stem	{cat}
blank	Space symbols		{}		
asciiword	Word, all ASCII	sat	{english_stem}	english_stem	{sat}
blank	Space symbols		{}		
asciiword	Word, all ASCII	on	{english_stem}	english_stem	{}
blank	Space symbols		{}		
asciiword	Word, all ASCII	a	{english_stem}	english_stem	{}
blank	Space symbols		{}		
asciiword	Word, all ASCII	mat	{english_stem}	english_stem	{mat}
blank	Space symbols		{}		
blank	Space symbols	-	{}		
asciiword	Word, all ASCII	it	{english_stem}	english_stem	{}
blank	Space symbols		{}		
asciiword	Word, all ASCII	ate	{english_stem}	english_stem	{ate}
blank	Space symbols		{}		
asciiword	Word, all ASCII	a	{english_stem}	english_stem	{}
blank	Space symbols		{}		
asciiword	Word, all ASCII	fat	{english_stem}	english_stem	{fat}
blank	Space symbols		{}		
asciiword	Word, all ASCII	rats	{english_stem}	english_stem	{rat}

For a more extensive demonstration, we first create a `public.english` configuration and `Ispell` dictionary for the English language:

```
CREATE TEXT SEARCH CONFIGURATION public.english ( COPY = pg_catalog.english );

CREATE TEXT SEARCH DICTIONARY english_ispell (
    TEMPLATE = ispell,
    DictFile = english,
    AffFile = english,
    StopWords = english
);
```

```
ALTER TEXT SEARCH CONFIGURATION public.english
  ALTER MAPPING FOR asciiword WITH english_ispell, english_stem;

SELECT * FROM ts_debug('public.english','The Brightest supernovaes');

```

alias	description	token	dictionaries	dictionary
asciiword	Word, all ASCII	The	{english_ispell,english_stem}	english_ispell
blank	Space symbols		{}	
asciiword	Word, all ASCII	Brightest	{english_ispell,english_stem}	english_ispell
blank	Space symbols		{}	
asciiword	Word, all ASCII	supernovaes	{english_ispell,english_stem}	english_stem

In this example, the word `Brightest` was recognized by the parser as an ASCII word (alias `asciiword`). For this token type the dictionary list is `english_ispell` and `english_stem`. The word was recognized by `english_ispell`, which reduced it to the noun `bright`. The word `supernovaes` is unknown to the `english_ispell` dictionary so it was passed to the next dictionary, and, fortunately, was recognized (in fact, `english_stem` is a Snowball dictionary which recognizes everything; that is why it was placed at the end of the dictionary list).

The word `The` was recognized by the `english_ispell` dictionary as a stop word (Section 12.6.1) and will not be indexed. The spaces are discarded too, since the configuration provides no dictionaries at all for them.

You can reduce the volume of output by explicitly specifying which columns you want to see:

```
SELECT alias, token, dictionary, lexemes
FROM ts_debug('public.english','The Brightest supernovaes');

```

alias	token	dictionary	lexemes
asciiword	The	english_ispell	{}
blank			
asciiword	Brightest	english_ispell	{bright}
blank			
asciiword	supernovaes	english_stem	{supernova}

## 12.8.2. Parser Testing

The following functions allow direct testing of a text search parser.

```
ts_parse(parser_name text, document text, OUT tokid integer, OUT token text) returns setof record
ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text) returns setof record
```

`ts_parse` parses the given *document* and returns a series of records, one for each token produced by parsing. Each record includes a `tokid` showing the assigned token type and a `token` which is the text of the token. For example:

```
SELECT * FROM ts_parse('default', '123 - a number');
 tokid | token
```

```

-----+-----
22 | 123
12 |
12 | -
1 | a
12 |
1 | number

```

```

ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text) return
ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text) return

```

`ts_token_type` returns a table which describes each type of token the specified parser can recognize. For each token type, the table gives the integer `tokid` that the parser uses to label a token of that type, the `alias` that names the token type in configuration commands, and a short `description`. For example:

```

SELECT * FROM ts_token_type('default');

```

tokid	alias	description
1	asciword	Word, all ASCII
2	word	Word, all letters
3	numword	Word, letters and digits
4	email	Email address
5	url	URL
6	host	Host
7	sfloat	Scientific notation
8	version	Version number
9	hword_numpart	Hyphenated word part, letters and digits
10	hword_part	Hyphenated word part, all letters
11	hword_asciipart	Hyphenated word part, all ASCII
12	blank	Space symbols
13	tag	XML tag
14	protocol	Protocol head
15	numhword	Hyphenated word, letters and digits
16	asciihword	Hyphenated word, all ASCII
17	hword	Hyphenated word, all letters
18	url_path	URL path
19	file	File or path name
20	float	Decimal notation
21	int	Signed integer
22	uint	Unsigned integer
23	entity	XML entity

### 12.8.3. Dictionary Testing

The `ts_lexize` function facilitates dictionary testing.

```
ts_lexize(dict regdictionary, token text) returns text[]
```

`ts_lexize` returns an array of lexemes if the input *token* is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or `NULL` if it is an unknown word.

Examples:

```
SELECT ts_lexize('english_stem', 'stars');
 ts_lexize
-----
 {star}

SELECT ts_lexize('english_stem', 'a');
 ts_lexize
-----
 {}
```

**Note:** The `ts_lexize` function expects a single *token*, not text. Here is a case where this can be confusing:

```
SELECT ts_lexize('thesaurus_astro','supernovae stars') is null;
 ?column?
-----
 t
```

The thesaurus dictionary `thesaurus_astro` does know the phrase `supernovae stars`, but `ts_lexize` fails since it does not parse the input text but treats it as a single token. Use `plainto_tsquery` or `to_tsvector` to test thesaurus dictionaries, for example:

```
SELECT plainto_tsquery('supernovae stars');
 plainto_tsquery
-----
 'sn'
```

## 12.9. GiST and GIN Index Types

There are two kinds of indexes that can be used to speed up full text searches. Note that indexes are not mandatory for full text searching, but in cases where a column is searched on a regular basis, an index

will usually be desirable.

```
CREATE INDEX name ON table USING gist(column);
```

Creates a GiST (Generalized Search Tree)-based index. The *column* can be of `tsvector` or `tsquery` type.

```
CREATE INDEX name ON table USING gin(column);
```

Creates a GIN (Generalized Inverted Index)-based index. The *column* must be of `tsvector` type.

There are substantial performance differences between the two index types, so it is important to understand which to use.

A GiST index is *lossy*, meaning that the index may produce false matches, and it is necessary to check the actual table row to eliminate such false matches. PostgreSQL does this automatically; for example, in the query plan below, the `Filter:` line indicates the index output will be rechecked:

```
EXPLAIN SELECT * FROM apod WHERE textsearch @@ to_tsquery('supernovae');
                                QUERY PLAN
-----
Index Scan using textsearch_gidx on apod  (cost=0.00..12.29 rows=2 width=1469)
  Index Cond: (textsearch @@ "'supernova'":tsquery)
  Filter: (textsearch @@ "'supernova'":tsquery)
```

GiST indexes are lossy because each document is represented in the index by a fixed-length signature. The signature is generated by hashing each word into a random bit in an *n*-bit string, with all these bits OR-ed together to produce an *n*-bit document signature. When two words hash to the same bit position there will be a false match. If all words in the query have matches (real or false) then the table row must be retrieved to see if the match is correct.

Lossiness causes performance degradation due to useless fetches of table records that turn out to be false matches. Since random access to table records is slow, this limits the usefulness of GiST indexes. The likelihood of false matches depends on several factors, in particular the number of unique words, so using dictionaries to reduce this number is recommended.

GIN indexes are not lossy but their performance depends logarithmically on the number of unique words.

Actually, GIN indexes store only the words (lexemes) of `tsvector` values, and not their weight labels. Thus, while a GIN index can be considered non-lossy for a query that does not specify weights, it is lossy for one that does. Thus a table row recheck is needed when using a query that involves weights. Unfortunately, in the current design of PostgreSQL, whether a recheck is needed is a static property of a particular operator, and not something that can be enabled or disabled on-the-fly depending on the values given to the operator. To deal with this situation without imposing the overhead of rechecks on queries that do not need them, the following approach has been adopted:

- The standard text match operator `@@` is marked as non-lossy for GIN indexes.
- An additional match operator `@@@` is provided, and marked as lossy for GIN indexes. This operator behaves exactly like `@@` otherwise.

- When a GIN index search is initiated with the @@ operator, the index support code will throw an error if the query specifies any weights. This protects against giving wrong answers due to failure to recheck the weights.

In short, you must use @@@ rather than @@ to perform GIN index searches on queries that involve weight restrictions. For queries that do not have weight restrictions, either operator will work, but @@ will be faster. This awkwardness will probably be addressed in a future release of PostgreSQL.

In choosing which index type to use, GiST or GIN, consider these performance differences:

- GIN index lookups are about three times faster than GiST
- GIN indexes take about three times longer to build than GiST
- GIN indexes are about ten times slower to update than GiST
- GIN indexes are two-to-three times larger than GiST

As a rule of thumb, GIN indexes are best for static data because lookups are faster. For dynamic data, GiST indexes are faster to update. Specifically, GiST indexes are very good for dynamic data and fast if the number of unique words (lexemes) is under 100,000, while GIN indexes will handle 100,000+ lexemes better but are slower to update.

Note that GIN index build time can often be improved by increasing `maintenance_work_mem`, while GiST index build time is not sensitive to that parameter.

Partitioning of big collections and the proper use of GiST and GIN indexes allows the implementation of very fast searches with online update. Partitioning can be done at the database level using table inheritance and `constraint_exclusion`, or by distributing documents over servers and collecting search results using the `contrib/dblink` extension module. The latter is possible because ranking functions use only local information.

## 12.10. psql Support

Information about text search configuration objects can be obtained in psql using a set of commands:

```
\dF{d,p,t} [ + ] [ PATTERN ]
```

An optional + produces more details.

The optional parameter `PATTERN` should be the name of a text search object, optionally schema-qualified. If `PATTERN` is omitted then information about all visible objects will be displayed. `PATTERN` can be a regular expression and can provide *separate* patterns for the schema and object names. The following examples illustrate this:

```
=> \dF *fulltext*
      List of text search configurations
 Schema | Name           | Description
-----+-----+-----
 public | fulltext_cfg   |

=> \dF *.fulltext*
```

```

      List of text search configurations
Schema | Name | Description
-----+-----
fulltext | fulltext_cfg |
public | fulltext_cfg |

```

The available commands are:

```
\dF[+] [PATTERN]
```

List text search configurations (add + for more detail).

```

=> \dF russian
      List of text search configurations
      Schema | Name | Description
      -----+-----
pg_catalog | russian | configuration for russian language

=> \dF+ russian
Text search configuration "pg_catalog.russian"
Parser: "pg_catalog.default"
      Token | Dictionaries
      -----+-----
asciihword | english_stem
asciword | english_stem
email | simple
file | simple
float | simple
host | simple
hword | russian_stem
hword_asciipart | english_stem

pg_catalog | snowball | snowball stemmer
pg_catalog | synonym | synonym dictionary: replace word by its synonym
pg_catalog | thesaurus | thesaurus dictionary: phrase by phrase substitution

```

## 12.11. Limitations

The current limitations of PostgreSQL's text search features are:

- The length of each lexeme must be less than 2K bytes
- The length of a `tsvector` (lexemes + positions) must be less than 1 megabyte
- The number of lexemes must be less than  $2^{64}$
- Position values in `tsvector` must be greater than 0 and no more than 16,383
- No more than 256 positions per lexeme
- The number of nodes (lexemes + operators) in a `tsquery` must be less than 32,768

For comparison, the PostgreSQL 8.1 documentation contained 10,441 unique words, a total of 335,420 words, and the most frequent word “postgresql” was mentioned 6,127 times in 655 documents.

Another example — the PostgreSQL mailing list archives contained 910,989 unique words with 57,491,343 lexemes in 461,020 messages.

## 12.12. Migration from Pre-8.3 Text Search

Applications that used the `contrib/tsearch2` add-on module for text searching will need some adjustments to work with the built-in features:

- Some functions have been renamed or had small adjustments in their argument lists, and all of them are now in the `pg_catalog` schema, whereas in a previous installation they would have been in `public`

or another non-system schema. There is a new version of `contrib/tsearch2` (see Section F.31) that provides a compatibility layer to solve most problems in this area.

- The old `contrib/tsearch2` functions and other objects *must* be suppressed when loading `pg_dump` output from a pre-8.3 database. While many of them won't load anyway, a few will and then cause problems. One simple way to deal with this is to load the new `contrib/tsearch2` module before restoring the dump; then it will block the old objects from being loaded.
- Text search configuration setup is completely different now. Instead of manually inserting rows into configuration tables, search is configured through the specialized SQL commands shown earlier in this chapter. There is not currently any automated support for converting an existing custom configuration for 8.3; you're on your own here.
- Most types of dictionaries rely on some outside-the-database configuration files. These are largely compatible with pre-8.3 usage, but note the following differences:
  - Configuration files now must be placed in a single specified directory (`$SHAREDIR/tsearch_data`), and must have a specific extension depending on the type of file, as noted previously in the descriptions of the various dictionary types. This restriction was added to forestall security problems.
  - Configuration files must be encoded in UTF-8 encoding, regardless of what database encoding is used.
  - In thesaurus configuration files, stop words must be marked with `?`.

# Chapter 13. Concurrency Control

This chapter describes the behavior of the PostgreSQL database system when two or more sessions try to access the same data at the same time. The goals in that situation are to allow efficient access for all sessions while maintaining strict data integrity. Every developer of database applications should be familiar with the topics covered in this chapter.

## 13.1. Introduction

PostgreSQL provides a rich set of tools for developers to manage concurrent access to data. Internally, data consistency is maintained by using a multiversion model (Multiversion Concurrency Control, MVCC). This means that while querying a database each transaction sees a snapshot of data (a *database version*) as it was some time ago, regardless of the current state of the underlying data. This protects the transaction from viewing inconsistent data that could be caused by (other) concurrent transaction updates on the same data rows, providing *transaction isolation* for each database session. MVCC, by eschewing explicit locking methodologies of traditional database systems, minimizes lock contention in order to allow for reasonable performance in multiuser environments.

The main advantage to using the MVCC model of concurrency control rather than locking is that in MVCC locks acquired for querying (reading) data do not conflict with locks acquired for writing data, and so reading never blocks writing and writing never blocks reading.

Table- and row-level locking facilities are also available in PostgreSQL for applications that cannot adapt easily to MVCC behavior. However, proper use of MVCC will generally provide better performance than locks. In addition, application-defined advisory locks provide a mechanism for acquiring locks that are not tied to a single transaction.

## 13.2. Transaction Isolation

The SQL standard defines four levels of transaction isolation in terms of three phenomena that must be prevented between concurrent transactions. These undesirable phenomena are:

dirty read

A transaction reads data written by a concurrent uncommitted transaction.

nonrepeatable read

A transaction re-reads data it has previously read and finds that data has been modified by another transaction (that committed since the initial read).

phantom read

A transaction re-executes a query returning a set of rows that satisfy a search condition and finds that the set of rows satisfying the condition has changed due to another recently-committed transaction.

The four transaction isolation levels and the corresponding behaviors are described in Table 13-1.

**Table 13-1. SQL Transaction Isolation Levels**

Isolation Level	Dirty Read	Nonrepeatable Read	Phantom Read
Read uncommitted	Possible	Possible	Possible
Read committed	Not possible	Possible	Possible
Repeatable read	Not possible	Not possible	Possible
Serializable	Not possible	Not possible	Not possible

In PostgreSQL, you can request any of the four standard transaction isolation levels. But internally, there are only two distinct isolation levels, which correspond to the levels Read Committed and Serializable. When you select the level Read Uncommitted you really get Read Committed, and when you select Repeatable Read you really get Serializable, so the actual isolation level might be stricter than what you select. This is permitted by the SQL standard: the four isolation levels only define which phenomena must not happen, they do not define which phenomena must happen. The reason that PostgreSQL only provides two isolation levels is that this is the only sensible way to map the standard isolation levels to the multiversion concurrency control architecture. The behavior of the available isolation levels is detailed in the following subsections.

To set the transaction isolation level of a transaction, use the command *SET TRANSACTION*.

### 13.2.1. Read Committed Isolation Level

*Read Committed* is the default isolation level in PostgreSQL. When a transaction runs on this isolation level, a *SELECT* query sees only data committed before the query began; it never sees either uncommitted data or changes committed during query execution by concurrent transactions. (However, the *SELECT* does see the effects of previous updates executed within its own transaction, even though they are not yet committed.) In effect, a *SELECT* query sees a snapshot of the database as of the instant that that query begins to run. Notice that two successive *SELECT* commands can see different data, even though they are within a single transaction, if other transactions commit changes during execution of the first *SELECT*.

*UPDATE*, *DELETE*, *SELECT FOR UPDATE*, and *SELECT FOR SHARE* commands behave the same as *SELECT* in terms of searching for target rows: they will only find target rows that were committed as of the command start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the would-be updater will wait for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the second updater can proceed with updating the originally found row. If the first updater commits, the second updater will ignore the row if the first updater deleted it, otherwise it will attempt to apply its operation to the updated version of the row. The search condition of the command (the *WHERE* clause) is re-evaluated to see if the updated version of the row still matches the search condition. If so, the second updater proceeds with its operation, starting from the updated version of the row. (In the case of *SELECT FOR UPDATE* and *SELECT FOR SHARE*, that means it is the updated version of the row that is locked and returned to the client.)

Because of the above rule, it is possible for an updating command to see an inconsistent snapshot: it can see the effects of concurrent updating commands that affected the same rows it is trying to update, but it does not see effects of those commands on other rows in the database. This behavior makes Read Committed mode unsuitable for commands that involve complex search conditions. However, it is just right for simpler cases. For example, consider updating bank balances with transactions like

```
BEGIN;
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 12345;
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 7534;
COMMIT;
```

If two such transactions concurrently try to change the balance of account 12345, we clearly want the second transaction to start from the updated version of the account's row. Because each command is affecting only a predetermined row, letting it see the updated version of the row does not create any troublesome inconsistency.

Since in Read Committed mode each new command starts with a new snapshot that includes all transactions committed up to that instant, subsequent commands in the same transaction will see the effects of the committed concurrent transaction in any case. The point at issue here is whether or not within a *single* command we see an absolutely consistent view of the database.

The partial transaction isolation provided by Read Committed mode is adequate for many applications, and this mode is fast and simple to use. However, for applications that do complex queries and updates, it might be necessary to guarantee a more rigorously consistent view of the database than the Read Committed mode provides.

### 13.2.2. Serializable Isolation Level

The level *Serializable* provides the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. However, applications using this level must be prepared to retry transactions due to serialization failures.

When a transaction is on the serializable level, a `SELECT` query sees only data committed before the transaction began; it never sees either uncommitted data or changes committed during transaction execution by concurrent transactions. (However, the `SELECT` does see the effects of previous updates executed within its own transaction, even though they are not yet committed.) This is different from Read Committed in that the `SELECT` sees a snapshot as of the start of the transaction, not as of the start of the current query within the transaction. Thus, successive `SELECT` commands within a single transaction always see the same data.

`UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands behave the same as `SELECT` in terms of searching for target rows: they will only find target rows that were committed as of the transaction start time. However, such a target row might have already been updated (or deleted or locked) by another concurrent transaction by the time it is found. In this case, the serializable transaction will wait for the first updating transaction to commit or roll back (if it is still in progress). If the first updater rolls back, then its effects are negated and the serializable transaction can proceed with updating the originally found row. But if the first updater commits (and actually updated or deleted the row, not just locked it) then the serializable transaction will be rolled back with the message

```
ERROR:  could not serialize access due to concurrent update
```

because a serializable transaction cannot modify or lock rows changed by other transactions after the serializable transaction began.

When the application receives this error message, it should abort the current transaction and then retry the whole transaction from the beginning. The second time through, the transaction sees the previously-

committed change as part of its initial view of the database, so there is no logical conflict in using the new version of the row as the starting point for the new transaction's update.

Note that only updating transactions might need to be retried; read-only transactions will never have serialization conflicts.

The Serializable mode provides a rigorous guarantee that each transaction sees a wholly consistent view of the database. However, the application has to be prepared to retry transactions when concurrent updates make it impossible to sustain the illusion of serial execution. Since the cost of redoing complex transactions might be significant, this mode is recommended only when updating transactions contain logic sufficiently complex that they might give wrong answers in Read Committed mode. Most commonly, Serializable mode is necessary when a transaction executes several successive commands that must see identical views of the database.

### 13.2.2.1. Serializable Isolation versus True Serializability

The intuitive meaning (and mathematical definition) of “serializable” execution is that any two successfully committed concurrent transactions will appear to have executed strictly serially, one after the other — although which one appeared to occur first might not be predictable in advance. It is important to realize that forbidding the undesirable behaviors listed in Table 13-1 is not sufficient to guarantee true serializability, and in fact PostgreSQL's Serializable mode *does not guarantee serializable execution in this sense*. As an example, consider a table `mytab`, initially containing

class	value
1	10
1	20
2	100
2	200

Suppose that serializable transaction A computes

```
SELECT SUM(value) FROM mytab WHERE class = 1;
```

and then inserts the result (30) as the `value` in a new row with `class = 2`. Concurrently, serializable transaction B computes

```
SELECT SUM(value) FROM mytab WHERE class = 2;
```

and obtains the result 300, which it inserts in a new row with `class = 1`. Then both transactions commit. None of the listed undesirable behaviors have occurred, yet we have a result that could not have occurred in either order serially. If A had executed before B, B would have computed the sum 330, not 300, and similarly the other order would have resulted in a different sum computed by A.

To guarantee true mathematical serializability, it is necessary for a database system to enforce *predicate locking*, which means that a transaction cannot insert or modify a row that would have matched the `WHERE` condition of a query in another concurrent transaction. For example, once transaction A has executed the query `SELECT ... WHERE class = 1`, a predicate-locking system would forbid transaction B from inserting any new row with class 1 until A has committed.<sup>1</sup> Such a locking system is complex to im-

1. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas MVCC prevents them by restricting what is read.

plement and extremely expensive in execution, since every session must be aware of the details of every query executed by every concurrent transaction. And this large expense is mostly wasted, since in practice most applications do not do the sorts of things that could result in problems. (Certainly the example above is rather contrived and unlikely to represent real software.) For these reasons, PostgreSQL does not implement predicate locking.

In those cases where the possibility of nonserializable execution is a real hazard, problems can be prevented by appropriate use of explicit locking. Further discussion appears in the following sections.

## 13.3. Explicit Locking

PostgreSQL provides various lock modes to control concurrent access to data in tables. These modes can be used for application-controlled locking in situations where MVCC does not give the desired behavior. Also, most PostgreSQL commands automatically acquire locks of appropriate modes to ensure that referenced tables are not dropped or modified in incompatible ways while the command executes. (For example, `ALTER TABLE` cannot safely be executed concurrently with other operations on the same table, so it obtains an exclusive lock on the table to enforce that.)

To examine a list of the currently outstanding locks in a database server, use the `pg_locks` system view. For more information on monitoring the status of the lock manager subsystem, refer to Chapter 26.

### 13.3.1. Table-Level Locks

The list below shows the available lock modes and the contexts in which they are used automatically by PostgreSQL. You can also acquire any of these locks explicitly with the command `LOCK`. Remember that all of these lock modes are table-level locks, even if the name contains the word “row”; the names of the lock modes are historical. To some extent the names reflect the typical usage of each lock mode — but the semantics are all the same. The only real difference between one lock mode and another is the set of lock modes with which each conflicts (see Table 13-2). . Two transactions cannot hold locks of conflicting modes on the same table at the same time. (However, a transaction never conflicts with itself. For example, it might acquire `ACCESS EXCLUSIVE` lock and later acquire `ACCESS SHARE` lock on the same table.) Non-conflicting lock modes can be held concurrently by many transactions. Notice in particular that some lock modes are self-conflicting (for example, an `ACCESS EXCLUSIVE` lock cannot be held by more than one transaction at a time) while others are not self-conflicting (for example, an `ACCESS SHARE` lock can be held by multiple transactions).

#### Table-level lock modes

`ACCESS SHARE`

Conflicts with the `ACCESS EXCLUSIVE` lock mode only.

The `SELECT` command acquires a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.

`ROW SHARE`

Conflicts with the `EXCLUSIVE` and `ACCESS EXCLUSIVE` lock modes.

The `SELECT FOR UPDATE` and `SELECT FOR SHARE` commands acquire a lock of this mode on the target table(s) (in addition to `ACCESS SHARE` locks on any other tables that are referenced but not selected `FOR UPDATE/FOR SHARE`).

#### ROW EXCLUSIVE

Conflicts with the `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes.

The commands `UPDATE`, `DELETE`, and `INSERT` acquire this lock mode on the target table (in addition to `ACCESS SHARE` locks on any other referenced tables). In general, this lock mode will be acquired by any command that modifies the data in a table.

#### SHARE UPDATE EXCLUSIVE

Conflicts with the `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent schema changes and `VACUUM` runs.

Acquired by `VACUUM (without FULL)`, `ANALYZE`, and `CREATE INDEX CONCURRENTLY`.

#### SHARE

Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent data changes.

Acquired by `CREATE INDEX (without CONCURRENTLY)`.

#### SHARE ROW EXCLUSIVE

Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes.

This lock mode is not automatically acquired by any PostgreSQL command.

#### EXCLUSIVE

Conflicts with the `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode allows only concurrent `ACCESS SHARE` locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode.

This lock mode is not automatically acquired on user tables by any PostgreSQL command. However it is acquired on certain system catalogs in some operations.

#### ACCESS EXCLUSIVE

Conflicts with locks of all modes (`ACCESS SHARE`, `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE`). This mode guarantees that the holder is the only transaction accessing the table in any way.

Acquired by the `ALTER TABLE`, `DROP TABLE`, `TRUNCATE`, `REINDEX`, `CLUSTER`, and `VACUUM FULL` commands. This is also the default lock mode for `LOCK TABLE` statements that do not specify a mode explicitly.

**Tip:** Only an `ACCESS EXCLUSIVE` lock blocks a `SELECT (without FOR UPDATE/SHARE)` statement.

Once acquired, a lock is normally held till end of transaction. But if a lock is acquired after establishing a savepoint, the lock is released immediately if the savepoint is rolled back to. This is consistent with the principle that `ROLLBACK` cancels all effects of the commands since the savepoint. The same holds for locks acquired within a PL/pgSQL exception block: an error escape from the block releases locks acquired within it.

**Table 13-2. Conflicting lock modes**

Requested Lock Mode	Current Lock Mode							
	ACCESS SHARE	ROW SHARE	ROW EXCLUSIVE	SHARE UPDATE EXCLUSIVE	SHARE	SHARE ROW EXCLUSIVE	EXCLUSIVE	ACCESS EXCLUSIVE
ACCESS SHARE								X
ROW SHARE							X	X
ROW EXCLUSIVE					X	X	X	X
SHARE UPDATE EXCLUSIVE				X	X	X	X	X
SHARE			X	X		X	X	X
SHARE ROW EXCLUSIVE			X	X	X	X	X	X
EXCLUSIVE		X	X	X	X	X	X	X
ACCESS EXCLUSIVE	X	X	X	X	X	X	X	X

### 13.3.2. Row-Level Locks

In addition to table-level locks, there are row-level locks, which can be exclusive or shared locks. An exclusive row-level lock on a specific row is automatically acquired when the row is updated or deleted.

The lock is held until the transaction commits or rolls back, in just the same way as for table-level locks. Row-level locks do not affect data querying; they block *writers to the same row* only.

To acquire an exclusive row-level lock on a row without actually modifying the row, select the row with `SELECT FOR UPDATE`. Note that once the row-level lock is acquired, the transaction can update the row multiple times without fear of conflicts.

To acquire a shared row-level lock on a row, select the row with `SELECT FOR SHARE`. A shared lock does not prevent other transactions from acquiring the same shared lock. However, no transaction is allowed to update, delete, or exclusively lock a row on which any other transaction holds a shared lock. Any attempt to do so will block until the shared lock(s) have been released.

PostgreSQL doesn't remember any information about modified rows in memory, so it has no limit to the number of rows locked at one time. However, locking a row might cause a disk write; thus, for example, `SELECT FOR UPDATE` will modify selected rows to mark them locked, and so will result in disk writes.

In addition to table and row locks, page-level share/exclusive locks are used to control read/write access to table pages in the shared buffer pool. These locks are released immediately after a row is fetched or updated. Application developers normally need not be concerned with page-level locks, but we mention them for completeness.

### 13.3.3. Deadlocks

The use of explicit locking can increase the likelihood of *deadlocks*, wherein two (or more) transactions each hold locks that the other wants. For example, if transaction 1 acquires an exclusive lock on table A and then tries to acquire an exclusive lock on table B, while transaction 2 has already exclusive-locked table B and now wants an exclusive lock on table A, then neither one can proceed. PostgreSQL automatically detects deadlock situations and resolves them by aborting one of the transactions involved, allowing the other(s) to complete. (Exactly which transaction will be aborted is difficult to predict and should not be relied on.)

Note that deadlocks can also occur as the result of row-level locks (and thus, they can occur even if explicit locking is not used). Consider the case in which there are two concurrent transactions modifying a table. The first transaction executes:

```
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 11111;
```

This acquires a row-level lock on the row with the specified account number. Then, the second transaction executes:

```
UPDATE accounts SET balance = balance + 100.00 WHERE acctnum = 22222;
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 11111;
```

The first `UPDATE` statement successfully acquires a row-level lock on the specified row, so it succeeds in updating that row. However, the second `UPDATE` statement finds that the row it is attempting to update has already been locked, so it waits for the transaction that acquired the lock to complete. Transaction two is now waiting on transaction one to complete before it continues execution. Now, transaction one executes:

```
UPDATE accounts SET balance = balance - 100.00 WHERE acctnum = 22222;
```

Transaction one attempts to acquire a row-level lock on the specified row, but it cannot: transaction two already holds such a lock. So it waits for transaction two to complete. Thus, transaction one is blocked

on transaction two, and transaction two is blocked on transaction one: a deadlock condition. PostgreSQL will detect this situation and abort one of the transactions.

The best defense against deadlocks is generally to avoid them by being certain that all applications using a database acquire locks on multiple objects in a consistent order. In the example above, if both transactions had updated the rows in the same order, no deadlock would have occurred. One should also ensure that the first lock acquired on an object in a transaction is the highest mode that will be needed for that object. If it is not feasible to verify this in advance, then deadlocks can be handled on-the-fly by retrying transactions that are aborted due to deadlock.

So long as no deadlock situation is detected, a transaction seeking either a table-level or row-level lock will wait indefinitely for conflicting locks to be released. This means it is a bad idea for applications to hold transactions open for long periods of time (e.g., while waiting for user input).

### 13.3.4. Advisory Locks

PostgreSQL provides a means for creating locks that have application-defined meanings. These are called *advisory locks*, because the system does not enforce their use — it is up to the application to use them correctly. Advisory locks can be useful for locking strategies that are an awkward fit for the MVCC model. Once acquired, an advisory lock is held until explicitly released or the session ends. Unlike standard locks, advisory locks do not honor transaction semantics: a lock acquired during a transaction that is later rolled back will still be held following the rollback, and likewise an unlock is effective even if the calling transaction fails later. The same lock can be acquired multiple times by its owning process: for each lock request there must be a corresponding unlock request before the lock is actually released. (If a session already holds a given lock, additional requests will always succeed, even if other sessions are awaiting the lock.) Like all locks in PostgreSQL, a complete list of advisory locks currently held by any session can be found in the `pg_locks` system view.

Advisory locks are allocated out of a shared memory pool whose size is defined by the configuration variables `max_locks_per_transaction` and `max_connections`. Care must be taken not to exhaust this memory or the server will not be able to grant any locks at all. This imposes an upper limit on the number of advisory locks grantable by the server, typically in the tens to hundreds of thousands depending on how the server is configured.

A common use of advisory locks is to emulate pessimistic locking strategies typical of so called “flat file” data management systems. While a flag stored in a table could be used for the same purpose, advisory locks are faster, avoid MVCC bloat, and are automatically cleaned up by the server at the end of the session. In certain cases using this method, especially in queries involving explicit ordering and `LIMIT` clauses, care must be taken to control the locks acquired because of the order in which SQL expressions are evaluated. For example:

```
SELECT pg_advisory_lock(id) FROM foo WHERE id = 12345; -- ok
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100; -- danger!
SELECT pg_advisory_lock(q.id) FROM
(
  SELECT id FROM foo WHERE id > 12345 LIMIT 100;
) q; -- ok
```

In the above queries, the second form is dangerous because the `LIMIT` is not guaranteed to be applied before the locking function is executed. This might cause some locks to be acquired that the application

was not expecting, and hence would fail to release (until it ends the session). From the point of view of the application, such locks would be dangling, although still viewable in `pg_locks`.

The functions provided to manipulate advisory locks are described in Table 9-56.

## 13.4. Data Consistency Checks at the Application Level

Because readers in PostgreSQL do not lock data, regardless of transaction isolation level, data read by one transaction can be overwritten by another concurrent transaction. In other words, if a row is returned by `SELECT` it doesn't mean that the row is still current at the instant it is returned (i.e., sometime after the current query began). The row might have been modified or deleted by an already-committed transaction that committed after this one started. Even if the row is still valid “now”, it could be changed or deleted before the current transaction does a commit or rollback.

Another way to think about it is that each transaction sees a snapshot of the database contents, and concurrently executing transactions might very well see different snapshots. So the whole concept of “now” is somewhat ill-defined anyway. This is not normally a big problem if the client applications are isolated from each other, but if the clients can communicate via channels outside the database then serious confusion might ensue.

To ensure the current validity of a row and protect it against concurrent updates one must use `SELECT FOR UPDATE`, `SELECT FOR SHARE`, or an appropriate `LOCK TABLE` statement. (`SELECT FOR UPDATE` or `SELECT FOR SHARE` locks just the returned rows against concurrent updates, while `LOCK TABLE` locks the whole table.) This should be taken into account when porting applications to PostgreSQL from other environments.

Global validity checks require extra thought under MVCC. For example, a banking application might wish to check that the sum of all credits in one table equals the sum of debits in another table, when both tables are being actively updated. Comparing the results of two successive `SELECT sum(...)` commands will not work reliably under Read Committed mode, since the second query will likely include the results of transactions not counted by the first. Doing the two sums in a single serializable transaction will give an accurate picture of the effects of transactions that committed before the serializable transaction started — but one might legitimately wonder whether the answer is still relevant by the time it is delivered. If the serializable transaction itself applied some changes before trying to make the consistency check, the usefulness of the check becomes even more debatable, since now it includes some but not all post-transaction-start changes. In such cases a careful person might wish to lock all tables needed for the check, in order to get an indisputable picture of current reality. A `SHARE` mode (or higher) lock guarantees that there are no uncommitted changes in the locked table, other than those of the current transaction.

Note also that if one is relying on explicit locking to prevent concurrent changes, one should use Read Committed mode, or in Serializable mode be careful to obtain the lock(s) before performing queries. A lock obtained by a serializable transaction guarantees that no other transactions modifying the table are still running, but if the snapshot seen by the transaction predates obtaining the lock, it might predate some now-committed changes in the table. A serializable transaction's snapshot is actually frozen at the start of its first query or data-modification command (`SELECT`, `INSERT`, `UPDATE`, or `DELETE`), so it's possible to obtain locks explicitly before the snapshot is frozen.

## 13.5. Locking and Indexes

Though PostgreSQL provides nonblocking read/write access to table data, nonblocking read/write access is not currently offered for every index access method implemented in PostgreSQL. The various index types are handled as follows:

### B-tree and GiST indexes

Short-term share/exclusive page-level locks are used for read/write access. Locks are released immediately after each index row is fetched or inserted. These index types provide the highest concurrency without deadlock conditions.

### Hash indexes

Share/exclusive hash-bucket-level locks are used for read/write access. Locks are released after the whole bucket is processed. Bucket-level locks provide better concurrency than index-level ones, but deadlock is possible since the locks are held longer than one index operation.

### GIN indexes

Short-term share/exclusive page-level locks are used for read/write access. Locks are released immediately after each index row is fetched or inserted. But note that a GIN-indexed value insertion usually produces several index key insertions per row, so GIN might do substantial work for a single value's insertion.

Currently, B-tree indexes offer the best performance for concurrent applications; since they also have more features than hash indexes, they are the recommended index type for concurrent applications that need to index scalar data. When dealing with non-scalar data, B-trees are not useful, and GiST or GIN indexes should be used instead.

# Chapter 14. Performance Tips

Query performance can be affected by many things. Some of these can be manipulated by the user, while others are fundamental to the underlying design of the system. This chapter provides some hints about understanding and tuning PostgreSQL performance.

## 14.1. Using `EXPLAIN`

PostgreSQL devises a *query plan* for each query it is given. Choosing the right plan to match the query structure and the properties of the data is absolutely critical for good performance, so the system includes a complex *planner* that tries to select good plans. You can use the `EXPLAIN` command to see what query plan the planner creates for any query. Plan-reading is an art that deserves an extensive tutorial, which this is not; but here is some basic information.

The structure of a query plan is a tree of *plan nodes*. Nodes at the bottom level are table scan nodes: they return raw rows from a table. There are different types of scan nodes for different table access methods: sequential scans, index scans, and bitmap index scans. If the query requires joining, aggregation, sorting, or other operations on the raw rows, then there will be additional nodes “atop” the scan nodes to perform these operations. Again, there is usually more than one possible way to do these operations, so different node types can appear here too. The output of `EXPLAIN` has one line for each node in the plan tree, showing the basic node type plus the cost estimates that the planner made for the execution of that plan node. The first line (topmost node) has the estimated total execution cost for the plan; it is this number that the planner seeks to minimize.

Here is a trivial example, just to show what the output looks like.<sup>1</sup>

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

The numbers that are quoted by `EXPLAIN` are:

- Estimated start-up cost (Time expended before output scan can start, e.g., time to do the sorting in a sort node.)
- Estimated total cost (If all rows were to be retrieved, though they might not be: for example, a query with a `LIMIT` clause will stop short of paying the total cost of the `Limit` plan node’s input node.)
- Estimated number of rows output by this plan node (Again, only if executed to completion.)
- Estimated average width (in bytes) of rows output by this plan node

---

1. Examples in this section are drawn from the regression test database after doing a `VACUUM ANALYZE`, using 8.2 development sources. You should be able to get similar results if you try the examples yourself, but your estimated costs and row counts will probably vary slightly because `ANALYZE`’s statistics are random samples rather than being exact.

The costs are measured in arbitrary units determined by the planner's cost parameters (see Section 18.6.2). Traditional practice is to measure the costs in units of disk page fetches; that is, `seq_page_cost` is conventionally set to 1.0 and the other cost parameters are set relative to that. The examples in this section are run with the default cost parameters.

It's important to note that the cost of an upper-level node includes the cost of all its child nodes. It's also important to realize that the cost only reflects things that the planner cares about. In particular, the cost does not consider the time spent transmitting result rows to the client, which could be an important factor in the true elapsed time; but the planner ignores it because it cannot change it by altering the plan. (Every correct plan will output the same row set, we trust.)

Rows output is a little tricky because it is *not* the number of rows processed or scanned by the plan node. It is usually less, reflecting the estimated selectivity of any `WHERE`-clause conditions that are being applied at the node. Ideally the top-level rows estimate will approximate the number of rows actually returned, updated, or deleted by the query.

Returning to our example:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

This is about as straightforward as it gets. If you do:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

you will find out that `tenk1` has 358 disk pages and 10000 rows. The estimated cost is (disk pages read \* `seq_page_cost`) + (rows scanned \* `cpu_tuple_cost`). By default, `seq_page_cost` is 1.0 and `cpu_tuple_cost` is 0.01. So the estimated cost is  $(358 * 1.0) + (10000 * 0.01) = 458$ .

Now let's modify the query to add a `WHERE` condition:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 7000;
```

QUERY PLAN

```
-----
Seq Scan on tenk1  (cost=0.00..483.00 rows=7033 width=244)
  Filter: (unique1 < 7000)
```

Notice that the `EXPLAIN` output shows the `WHERE` clause being applied as a “filter” condition; this means that the plan node checks the condition for each row it scans, and outputs only the ones that pass the condition. The estimate of output rows has gone down because of the `WHERE` clause. However, the scan will still have to visit all 10000 rows, so the cost hasn't decreased; in fact it has gone up a bit (by  $10000 * \text{cpu\_operator\_cost}$ , to be exact) to reflect the extra CPU time spent checking the `WHERE` condition.

The actual number of rows this query would select is 7000, but the rows estimate is only approximate. If you try to duplicate this experiment, you will probably get a slightly different estimate; moreover, it will change after each `ANALYZE` command, because the statistics produced by `ANALYZE` are taken from a randomized sample of the table.

Now, let's make the condition more restrictive:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 100;
```

QUERY PLAN

```
-----
Bitmap Heap Scan on tenk1  (cost=2.37..232.35 rows=106 width=244)
  Recheck Cond: (unique1 < 100)
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..2.37 rows=106 width=0)
        Index Cond: (unique1 < 100)
```

Here the planner has decided to use a two-step plan: the bottom plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching the rows separately is much more expensive than sequentially reading them, but because not all the pages of the table have to be visited, this is still cheaper than a sequential scan. (The reason for using two levels of plan is that the upper plan node sorts the row locations identified by the index into physical order before reading them, so as to minimize the costs of the separate fetches. The “bitmap” mentioned in the node names is the mechanism that does the sorting.)

If the `WHERE` condition is selective enough, the planner might switch to a “simple” index scan plan:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 3;
```

QUERY PLAN

```
-----
Index Scan using tenk1_unique1 on tenk1  (cost=0.00..10.00 rows=2 width=244)
  Index Cond: (unique1 < 3)
```

In this case the table rows are fetched in index order, which makes them even more expensive to read, but there are so few that the extra cost of sorting the row locations is not worth it. You’ll most often see this plan type for queries that fetch just a single row, and for queries that request an `ORDER BY` condition that matches the index order.

Add another condition to the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 3 AND stringu1 = 'xxx';
```

QUERY PLAN

```
-----
Index Scan using tenk1_unique1 on tenk1  (cost=0.00..10.01 rows=1 width=244)
  Index Cond: (unique1 < 3)
  Filter: (stringu1 = 'xxx'::name)
```

The added condition `stringu1 = 'xxx'` reduces the output-rows estimate, but not the cost because we still have to visit the same set of rows. Notice that the `stringu1` clause cannot be applied as an index condition (since this index is only on the `unique1` column). Instead it is applied as a filter on the rows retrieved by the index. Thus the cost has actually gone up a little bit to reflect this extra checking.

If there are indexes on several columns used in `WHERE`, the planner might choose to use an `AND` or `OR` combination of the indexes:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 100 AND unique2 > 9000;
```

QUERY PLAN

```

Bitmap Heap Scan on tenk1  (cost=11.27..49.11 rows=11 width=244)
  Recheck Cond: ((unique1 < 100) AND (unique2 > 9000))
-> BitmapAnd  (cost=11.27..11.27 rows=11 width=0)
     -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..2.37 rows=106 width=0)
        Index Cond: (unique1 < 100)
     -> Bitmap Index Scan on tenk1_unique2  (cost=0.00..8.65 rows=1042 width=0)
        Index Cond: (unique2 > 9000)

```

But this requires visiting both indexes, so it's not necessarily a win compared to using just one index and treating the other condition as a filter. If you vary the ranges involved you'll see the plan change accordingly.

Let's try joining two tables, using the columns we have been discussing:

```
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2 WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2
```

#### QUERY PLAN

```

-----
Nested Loop  (cost=2.37..553.11 rows=106 width=488)
-> Bitmap Heap Scan on tenk1 t1  (cost=2.37..232.35 rows=106 width=244)
     Recheck Cond: (unique1 < 100)
     -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..2.37 rows=106 width=0)
        Index Cond: (unique1 < 100)
-> Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..3.01 rows=1 width=244)
     Index Cond: (t2.unique2 = t1.unique2)

```

In this nested-loop join, the outer scan is the same bitmap index scan we saw earlier, and so its cost and row count are the same because we are applying the `WHERE` clause `unique1 < 100` at that node. The `t1.unique2 = t2.unique2` clause is not relevant yet, so it doesn't affect row count of the outer scan. For the inner scan, the `unique2` value of the current outer-scan row is plugged into the inner index scan to produce an index condition like `t2.unique2 = constant`. So we get the same inner-scan plan and costs that we'd get from, say, `EXPLAIN SELECT * FROM tenk2 WHERE unique2 = 42`. The costs of the loop node are then set on the basis of the cost of the outer scan, plus one repetition of the inner scan for each outer row ( $106 * 3.01$ , here), plus a little CPU time for join processing.

In this example the join's output row count is the same as the product of the two scans' row counts, but that's not true in general, because in general you can have `WHERE` clauses that mention both tables and so can only be applied at the join point, not to either input scan. For example, if we added `WHERE ... AND t1.hundred < t2.hundred`, that would decrease the output row count of the join node, but not change either input scan.

One way to look at variant plans is to force the planner to disregard whatever strategy it thought was the winner, using the enable/disable flags described in Section 18.6.1. (This is a crude tool, but useful. See also Section 14.3.)

```

SET enable_nestloop = off;
EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2 WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2

```

#### QUERY PLAN

```

-----
Hash Join  (cost=232.61..741.67 rows=106 width=488)
  Hash Cond: (t2.unique2 = t1.unique2)

```

```

-> Seq Scan on tenk2 t2 (cost=0.00..458.00 rows=10000 width=244)
-> Hash (cost=232.35..232.35 rows=106 width=244)
    -> Bitmap Heap Scan on tenk1 t1 (cost=2.37..232.35 rows=106 width=244)
        Recheck Cond: (unique1 < 100)
        -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0)
            Index Cond: (unique1 < 100)

```

This plan proposes to extract the 100 interesting rows of `tenk1` using that same old index scan, stash them into an in-memory hash table, and then do a sequential scan of `tenk2`, probing into the hash table for possible matches of `t1.unique2 = t2.unique2` at each `tenk2` row. The cost to read `tenk1` and set up the hash table is entirely start-up cost for the hash join, since we won't get any rows out until we can start reading `tenk2`. The total time estimate for the join also includes a hefty charge for the CPU time to probe the hash table 10000 times. Note, however, that we are *not* charging 10000 times 232.35; the hash table setup is only done once in this plan type.

It is possible to check on the accuracy of the planner's estimated costs by using `EXPLAIN ANALYZE`. This command actually executes the query, and then displays the true run time accumulated within each plan node along with the same estimated costs that a plain `EXPLAIN` shows. For example, we might get a result like this:

```
EXPLAIN ANALYZE SELECT * FROM tenk1 t1, tenk2 t2 WHERE t1.unique1 < 100 AND t1.unique2 = t2.unique2
```

#### QUERY PLAN

```

-----
Nested Loop (cost=2.37..553.11 rows=106 width=488) (actual time=1.392..12.700 rows=100 loops=1)
  -> Bitmap Heap Scan on tenk1 t1 (cost=2.37..232.35 rows=106 width=244) (actual time=0.000..0.000 rows=106)
      Recheck Cond: (unique1 < 100)
      -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..2.37 rows=106 width=0) (actual time=0.000..0.000 rows=106)
          Index Cond: (unique1 < 100)
  -> Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..3.01 rows=1 width=244) (actual time=0.000..0.000 rows=1)
      Index Cond: (t2.unique2 = t1.unique2)
Total runtime: 14.452 ms

```

Note that the “actual time” values are in milliseconds of real time, whereas the “cost” estimates are expressed in arbitrary units; so they are unlikely to match up. The thing to pay attention to is whether the ratios of actual time and estimated costs are consistent.

In some query plans, it is possible for a subplan node to be executed more than once. For example, the inner index scan is executed once per outer row in the above nested-loop plan. In such cases, the “loops” value reports the total number of executions of the node, and the actual time and rows values shown are averages per-execution. This is done to make the numbers comparable with the way that the cost estimates are shown. Multiply by the “loops” value to get the total time actually spent in the node.

The `Total runtime` shown by `EXPLAIN ANALYZE` includes executor start-up and shut-down time, as well as time spent processing the result rows. It does not include parsing, rewriting, or planning time. For a `SELECT` query, the total run time will normally be just a little larger than the total time reported for the top-level plan node. For `INSERT`, `UPDATE`, and `DELETE` commands, the total run time might be considerably larger, because it includes the time spent processing the result rows. In these commands, the time for the top plan node essentially is the time spent computing the new rows and/or locating the old ones, but it doesn't include the time spent applying the changes. Time spent firing triggers, if any, is also outside the top plan node, and is shown separately for each trigger.

It is worth noting that `EXPLAIN` results should not be extrapolated to situations other than the one you are actually testing; for example, results on a toy-sized table cannot be assumed to apply to large tables. The planner's cost estimates are not linear and so it might choose a different plan for a larger or smaller table. An extreme example is that on a table that only occupies one disk page, you'll nearly always get a sequential scan plan whether indexes are available or not. The planner realizes that it's going to take one disk page read to process the table in any case, so there's no value in expending additional page reads to look at an index.

## 14.2. Statistics Used by the Planner

As we saw in the previous section, the query planner needs to estimate the number of rows retrieved by a query in order to make good choices of query plans. This section provides a quick look at the statistics that the system uses for these estimates.

One component of the statistics is the total number of entries in each table and index, as well as the number of disk blocks occupied by each table and index. This information is kept in the table `pg_class`, in the columns `reltuples` and `relpages`. We can look at it with queries similar to this one:

```
SELECT relname, relkind, reltuples, relpages FROM pg_class WHERE relname LIKE 'tenk1%';
```

relname	relkind	reltuples	relpages
tenk1	r	10000	358
tenk1_hundred	i	10000	30
tenk1_thous_tenthous	i	10000	30
tenk1_unique1	i	10000	30
tenk1_unique2	i	10000	30

(5 rows)

Here we can see that `tenk1` contains 10000 rows, as do its indexes, but the indexes are (unsurprisingly) much smaller than the table.

For efficiency reasons, `reltuples` and `relpages` are not updated on-the-fly, and so they usually contain somewhat out-of-date values. They are updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`. A stand-alone `ANALYZE`, that is one not part of `VACUUM`, generates an approximate `reltuples` value since it does not read every row of the table. The planner will scale the values it finds in `pg_class` to match the current physical table size, thus obtaining a closer approximation.

Most queries retrieve only a fraction of the rows in a table, due to having `WHERE` clauses that restrict the rows to be examined. The planner thus needs to make an estimate of the *selectivity* of `WHERE` clauses, that is, the fraction of rows that match each condition in the `WHERE` clause. The information used for this task is stored in the `pg_statistic` system catalog. Entries in `pg_statistic` are updated by the `ANALYZE` and `VACUUM ANALYZE` commands, and are always approximate even when freshly updated.

Rather than look at `pg_statistic` directly, it's better to look at its view `pg_stats` when examining the statistics manually. `pg_stats` is designed to be more easily readable. Furthermore, `pg_stats` is readable by all, whereas `pg_statistic` is only readable by a superuser. (This prevents unprivileged users from learning something about the contents of other people's tables from the statistics. The `pg_stats` view is restricted to show only rows about tables that the current user can read.) For example, we might do:

```
SELECT attname, n_distinct, most_common_vals FROM pg_stats WHERE tablename = 'road';
```

```

attname | n_distinct |
-----+-----+-----
name    | -0.467008 | {"I- 580                                Ramp", "I- 880
thepath |          20 | {"[(-122.089,37.71), (-122.0886,37.711)]"}
(2 rows)
```

The amount of information stored in `pg_statistic` by `ANALYZE`, in particular the maximum number of entries in the `most_common_vals` and `histogram_bounds` arrays for each column, can be set on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` configuration variable. The default limit is presently 10 entries. Raising the limit might allow more accurate planner estimates to be made, particularly for columns with irregular data distributions, at the price of consuming more space in `pg_statistic` and slightly more time to compute the estimates. Conversely, a lower limit might be sufficient for columns with simple data distributions.

Further details about the planner's use of statistics can be found in Chapter 55.

## 14.3. Controlling the Planner with Explicit JOIN Clauses

It is possible to control the query planner to some extent by using the explicit `JOIN` syntax. To see why this matters, we first need some background.

In a simple join query, such as:

```
SELECT * FROM a, b, c WHERE a.id = b.id AND b.ref = c.id;
```

the planner is free to join the given tables in any order. For example, it could generate a query plan that joins A to B, using the `WHERE` condition `a.id = b.id`, and then joins C to this joined table, using the other `WHERE` condition. Or it could join B to C and then join A to that result. Or it could join A to C and then join them with B — but that would be inefficient, since the full Cartesian product of A and C would have to be formed, there being no applicable condition in the `WHERE` clause to allow optimization of the join. (All joins in the PostgreSQL executor happen between two input tables, so it's necessary to build up the result in one or another of these fashions.) The important point is that these different join possibilities give semantically equivalent results but might have hugely different execution costs. Therefore, the planner will explore all of them to try to find the most efficient query plan.

When a query only involves two or three tables, there aren't many join orders to worry about. But the number of possible join orders grows exponentially as the number of tables expands. Beyond ten or so input tables it's no longer practical to do an exhaustive search of all the possibilities, and even for six or seven tables planning might take an annoyingly long time. When there are too many input tables, the PostgreSQL planner will switch from exhaustive search to a *genetic* probabilistic search through a limited number of possibilities. (The switch-over threshold is set by the `geqo_threshold` run-time parameter.) The genetic search takes less time, but it won't necessarily find the best possible plan.

When the query involves outer joins, the planner has less freedom than it does for plain (inner) joins. For example, consider:

```
SELECT * FROM a LEFT JOIN (b JOIN c ON (b.ref = c.id)) ON (a.id = b.id);
```

Although this query's restrictions are superficially similar to the previous example, the semantics are different because a row must be emitted for each row of A that has no matching row in the join of B and C. Therefore the planner has no choice of join order here: it must join B to C and then join A to that result. Accordingly, this query takes less time to plan than the previous query. In other cases, the planner might be able to determine that more than one join order is safe. For example, given:

```
SELECT * FROM a LEFT JOIN b ON (a.bid = b.id) LEFT JOIN c ON (a.cid = c.id);
```

it is valid to join A to either B or C first. Currently, only `FULL JOIN` completely constrains the join order. Most practical cases involving `LEFT JOIN` or `RIGHT JOIN` can be rearranged to some extent.

Explicit inner join syntax (`INNER JOIN`, `CROSS JOIN`, or unadorned `JOIN`) is semantically the same as listing the input relations in `FROM`, so it does not constrain the join order.

Even though most kinds of `JOIN` don't completely constrain the join order, it is possible to instruct the PostgreSQL query planner to treat all `JOIN` clauses as constraining the join order anyway. For example, these three queries are logically equivalent:

```
SELECT * FROM a, b, c WHERE a.id = b.id AND b.ref = c.id;
SELECT * FROM a CROSS JOIN b CROSS JOIN c WHERE a.id = b.id AND b.ref = c.id;
SELECT * FROM a JOIN (b JOIN c ON (b.ref = c.id)) ON (a.id = b.id);
```

But if we tell the planner to honor the `JOIN` order, the second and third take less time to plan than the first. This effect is not worth worrying about for only three tables, but it can be a lifesaver with many tables.

To force the planner to follow the join order laid out by explicit `JOINS`, set the `join_collapse_limit` run-time parameter to 1. (Other possible values are discussed below.)

You do not need to constrain the join order completely in order to cut search time, because it's OK to use `JOIN` operators within items of a plain `FROM` list. For example, consider:

```
SELECT * FROM a CROSS JOIN b, c, d, e WHERE ...;
```

With `join_collapse_limit = 1`, this forces the planner to join A to B before joining them to other tables, but doesn't constrain its choices otherwise. In this example, the number of possible join orders is reduced by a factor of 5.

Constraining the planner's search in this way is a useful technique both for reducing planning time and for directing the planner to a good query plan. If the planner chooses a bad join order by default, you can force it to choose a better order via `JOIN` syntax — assuming that you know of a better order, that is. Experimentation is recommended.

A closely related issue that affects planning time is collapsing of subqueries into their parent query. For example, consider:

```
SELECT *
FROM x, y,
     (SELECT * FROM a, b, c WHERE something) AS ss
WHERE somethingelse;
```

This situation might arise from use of a view that contains a join; the view's `SELECT` rule will be inserted in place of the view reference, yielding a query much like the above. Normally, the planner will try to collapse the subquery into the parent, yielding:

```
SELECT * FROM x, y, a, b, c WHERE something AND somethingelse;
```

This usually results in a better plan than planning the subquery separately. (For example, the outer `WHERE` conditions might be such that joining `X` to `A` first eliminates many rows of `A`, thus avoiding the need to form the full logical output of the subquery.) But at the same time, we have increased the planning time; here, we have a five-way join problem replacing two separate three-way join problems. Because of the exponential growth of the number of possibilities, this makes a big difference. The planner tries to avoid getting stuck in huge join search problems by not collapsing a subquery if more than `from_collapse_limit` `FROM` items would result in the parent query. You can trade off planning time against quality of plan by adjusting this run-time parameter up or down.

`from_collapse_limit` and `join_collapse_limit` are similarly named because they do almost the same thing: one controls when the planner will “flatten out” subqueries, and the other controls when it will flatten out explicit joins. Typically you would either set `join_collapse_limit` equal to `from_collapse_limit` (so that explicit joins and subqueries act similarly) or set `join_collapse_limit` to 1 (if you want to control join order with explicit joins). But you might set them differently if you are trying to fine-tune the trade-off between planning time and run time.

## 14.4. Populating a Database

One might need to insert a large amount of data when first populating a database. This section contains some suggestions on how to make this process as efficient as possible.

### 14.4.1. Disable Autocommit

Turn off autocommit and just do one commit at the end. (In plain SQL, this means issuing `BEGIN` at the start and `COMMIT` at the end. Some client libraries might do this behind your back, in which case you need to make sure the library does it when you want it done.) If you allow each insertion to be committed separately, PostgreSQL is doing a lot of work for each row that is added. An additional benefit of doing all insertions in one transaction is that if the insertion of one row were to fail then the insertion of all rows inserted up to that point would be rolled back, so you won’t be stuck with partially loaded data.

### 14.4.2. Use `COPY`

Use `COPY` to load all the rows in one command, instead of using a series of `INSERT` commands. The `COPY` command is optimized for loading large numbers of rows; it is less flexible than `INSERT`, but incurs significantly less overhead for large data loads. Since `COPY` is a single command, there is no need to disable autocommit if you use this method to populate a table.

If you cannot use `COPY`, it might help to use `PREPARE` to create a prepared `INSERT` statement, and then use `EXECUTE` as many times as required. This avoids some of the overhead of repeatedly parsing and planning `INSERT`. Different interfaces provide this facility in different ways; look for “prepared statements” in the interface documentation.

Note that loading a large number of rows using `COPY` is almost always faster than using `INSERT`, even if `PREPARE` is used and multiple insertions are batched into a single transaction.

`COPY` is fastest when used within the same transaction as an earlier `CREATE TABLE` or `TRUNCATE` command. In such cases no WAL needs to be written, because in case of an error, the files containing the newly

loaded data will be removed anyway. However, this consideration does not apply when `archive_mode` is set, as all commands must write WAL in that case.

### 14.4.3. Remove Indexes

If you are loading a freshly created table, the fastest way is to create the table, bulk load the table's data using `COPY`, then create any indexes needed for the table. Creating an index on pre-existing data is quicker than updating it incrementally as each row is loaded.

If you are adding large amounts of data to an existing table, it might be a win to drop the index, load the table, and then recreate the index. Of course, the database performance for other users might be adversely affected during the time that the index is missing. One should also think twice before dropping unique indexes, since the error checking afforded by the unique constraint will be lost while the index is missing.

### 14.4.4. Remove Foreign Key Constraints

Just as with indexes, a foreign key constraint can be checked “in bulk” more efficiently than row-by-row. So it might be useful to drop foreign key constraints, load data, and re-create the constraints. Again, there is a trade-off between data load speed and loss of error checking while the constraint is missing.

### 14.4.5. Increase `maintenance_work_mem`

Temporarily increasing the `maintenance_work_mem` configuration variable when loading large amounts of data can lead to improved performance. This will help to speed up `CREATE INDEX` commands and `ALTER TABLE ADD FOREIGN KEY` commands. It won't do much for `COPY` itself, so this advice is only useful when you are using one or both of the above techniques.

### 14.4.6. Increase `checkpoint_segments`

Temporarily increasing the `checkpoint_segments` configuration variable can also make large data loads faster. This is because loading a large amount of data into PostgreSQL will cause checkpoints to occur more often than the normal checkpoint frequency (specified by the `checkpoint_timeout` configuration variable). Whenever a checkpoint occurs, all dirty pages must be flushed to disk. By increasing `checkpoint_segments` temporarily during bulk data loads, the number of checkpoints that are required can be reduced.

### 14.4.7. Turn off `archive_mode`

When loading large amounts of data into an installation that uses WAL archiving, you might want to disable archiving (turn off the `archive_mode` configuration variable) while loading. It might be faster to take a new base backup after the load has completed than to process a large amount of incremental WAL data. But note that turning `archive_mode` on or off requires a server restart.

Aside from avoiding the time for the archiver to process the WAL data, doing this will actually make certain commands faster, because they are designed not to write WAL at all if `archive_mode` is off. (They can guarantee crash safety more cheaply by doing an `fsync` at the end than by writing WAL.) This applies to the following commands:

- `CREATE TABLE AS SELECT`
- `CREATE INDEX` (and variants such as `ALTER TABLE ADD PRIMARY KEY`)
- `ALTER TABLE SET TABLESPACE`
- `CLUSTER`
- `COPY FROM`, when the target table has been created or truncated earlier in the same transaction

### 14.4.8. Run `ANALYZE` Afterwards

Whenever you have significantly altered the distribution of data within a table, running `ANALYZE` is strongly recommended. This includes bulk loading large amounts of data into the table. Running `ANALYZE` (or `VACUUM ANALYZE`) ensures that the planner has up-to-date statistics about the table. With no statistics or obsolete statistics, the planner might make poor decisions during query planning, leading to poor performance on any tables with inaccurate or nonexistent statistics.

### 14.4.9. Some Notes About `pg_dump`

Dump scripts generated by `pg_dump` automatically apply several, but not all, of the above guidelines. To reload a `pg_dump` dump as quickly as possible, you need to do a few extra things manually. (Note that these points apply while *restoring* a dump, not while *creating* it. The same points apply when using `pg_restore` to load from a `pg_dump` archive file.)

By default, `pg_dump` uses `COPY`, and when it is generating a complete schema-and-data dump, it is careful to load data before creating indexes and foreign keys. So in this case several guidelines are handled automatically. What is left for you to do is to:

- Set appropriate (i.e., larger than normal) values for `maintenance_work_mem` and `checkpoint_segments`.
- If using WAL archiving, consider disabling it during the restore. To do that, turn off `archive_mode` before loading the dump script, and afterwards turn it back on and take a fresh base backup.
- Consider whether the whole dump should be restored as a single transaction. To do that, pass the `-1` or `--single-transaction` command-line option to `psql` or `pg_restore`. When using this mode, even the smallest of errors will rollback the entire restore, possibly discarding many hours of processing. Depending on how interrelated the data is, that might seem preferable to manual cleanup, or not. `COPY` commands will run fastest if you use a single transaction and have WAL archiving turned off.
- Run `ANALYZE` afterwards.

A data-only dump will still use `COPY`, but it does not drop or recreate indexes, and it does not normally touch foreign keys.<sup>2</sup> So when loading a data-only dump, it is up to you to drop and recreate indexes and foreign keys if you wish to use those techniques. It's still useful to increase `checkpoint_segments` while loading the data, but don't bother increasing `maintenance_work_mem`; rather, you'd do that while manually recreating indexes and foreign keys afterwards. And don't forget to `ANALYZE` when you're done.

---

2. You can get the effect of disabling foreign keys by using the `--disable-triggers` option — but realize that that eliminates, rather than just postponing, foreign key validation, and so it is possible to insert bad data if you use it.

# III. Server Administration

This part covers topics that are of interest to a PostgreSQL database administrator. This includes installation of the software, set up and configuration of the server, management of users and databases, and maintenance tasks. Anyone who runs a PostgreSQL server, even for personal use, but especially in production, should be familiar with the topics covered in this part.

The information in this part is arranged approximately in the order in which a new user should read it. But the chapters are self-contained and can be read individually as desired. The information in this part is presented in a narrative fashion in topical units. Readers looking for a complete description of a particular command should look into Part VI.

The first few chapters are written so that they can be understood without prerequisite knowledge, so that new users who need to set up their own server can begin their exploration with this part. The rest of this part is about tuning and management; that material assumes that the reader is familiar with the general use of the PostgreSQL database system. Readers are encouraged to look at Part I and Part II for additional information.

# Chapter 15. Installation Instructions

This chapter describes the installation of PostgreSQL from the source code distribution. (If you are installing a pre-packaged distribution, such as an RPM or Debian package, ignore this chapter and read the packager's instructions instead.)

## 15.1. Short Version

```
./configure
gmake
su
gmake install
adduser postgres
mkdir /usr/local/pgsql/data
chown postgres /usr/local/pgsql/data
su - postgres
/usr/local/pgsql/bin/initdb -D /usr/local/pgsql/data
/usr/local/pgsql/bin/postgres -D /usr/local/pgsql/data >logfile 2>&1 &
/usr/local/pgsql/bin/createdb test
/usr/local/pgsql/bin/psql test
```

The long version is the rest of this chapter.

## 15.2. Requirements

In general, a modern Unix-compatible platform should be able to run PostgreSQL. The platforms that had received specific testing at the time of release are listed in Section 15.7 below. In the `doc` subdirectory of the distribution there are several platform-specific FAQ documents you might wish to consult if you are having trouble.

The following software packages are required for building PostgreSQL:

- GNU make is required; other make programs will *not* work. GNU make is often installed under the name `gmake`; this document will always refer to it by that name. (On some systems GNU make is the default tool with the name `make`.) To test for GNU make enter

```
gmake --version
```

It is recommended to use version 3.76.1 or later.

- You need an ISO/ANSI C compiler. Recent versions of GCC are recommendable, but PostgreSQL is known to build with a wide variety of compilers from different vendors.
- tar is required to unpack the source distribution in the first place, in addition to either gzip or bzip2.
- The GNU Readline library (for simple line editing and command history retrieval) is used by default. If you don't want to use it then you must specify the `--without-readline` option for `configure`. As an alternative, you can often use the BSD-licensed `libedit` library, originally developed on NetBSD. The `libedit` library is GNU Readline-compatible and is used if `libreadline` is not found, or if

`--with-libedit-preferred` is used as an option to `configure`. If you are using a package-based Linux distribution, be aware that you need both the `readline` and `readline-devel` packages, if those are separate in your distribution.

- The `zlib` compression library will be used by default. If you don't want to use it then you must specify the `--without-zlib` option for `configure`. Using this option disables support for compressed archives in `pg_dump` and `pg_restore`.

The following packages are optional. They are not required in the default configuration, but they are needed when certain build options are enabled, as explained below.

- To build the server programming language PL/Perl you need a full Perl installation, including the `libperl` library and the header files. Since PL/Perl will be a shared library, the `libperl` library must be a shared library also on most platforms. This appears to be the default in recent Perl versions, but it was not in earlier versions, and in any case it is the choice of whomever installed Perl at your site.

If you don't have the shared library but you need one, a message like this will appear during the build to point out this fact:

```
*** Cannot build PL/Perl because libperl is not a shared library.
*** You might have to rebuild your Perl installation. Refer to
*** the documentation for details.
```

(If you don't follow the on-screen output you will merely notice that the PL/Perl library object, `plperl.so` or similar, will not be installed.) If you see this, you will have to rebuild and install Perl manually to be able to build PL/Perl. During the configuration process for Perl, request a shared library.

- To build the PL/Python server programming language, you need a Python installation with the header files and the `distutils` module. The `distutils` module is included by default with Python 1.6 and later; users of earlier versions of Python will need to install it.

Since PL/Python will be a shared library, the `libpython` library must be a shared library also on most platforms. This is not the case in a default Python installation. If after building and installing you have a file called `plpython.so` (possibly a different extension), then everything went well. Otherwise you should have seen a notice like this flying by:

```
*** Cannot build PL/Python because libpython is not a shared library.
*** You might have to rebuild your Python installation. Refer to
*** the documentation for details.
```

That means you have to rebuild (part of) your Python installation to supply this shared library.

If you have problems, run Python 2.3 or later's `configure` using the `--enable-shared` flag. On some operating systems you don't have to build a shared library, but you will have to convince the PostgreSQL build system of this. Consult the `Makefile` in the `src/pl/plpython` directory for details.

- If you want to build the PL/Tcl procedural language, you of course need a Tcl installation. If you are using a pre-8.4 release of Tcl, ensure that it was built without multithreading support.
- To enable Native Language Support (NLS), that is, the ability to display a program's messages in a language other than English, you need an implementation of the `Gettext` API. Some operating systems have this built-in (e.g., Linux, NetBSD, Solaris), for other systems you can download an add-on package from <http://developer.postgresql.org/~petere/bsd-gettext/>. If you are using the `Gettext` imple-

mentation in the GNU C library then you will additionally need the GNU Gettext package for some utility programs. For any of the other implementations you will not need it.

- Kerberos, OpenSSL, OpenLDAP, and/or PAM, if you want to support authentication or encryption using these services.

If you are building from a CVS tree instead of using a released source package, or if you want to do development, you also need the following packages:

- GNU Flex and Bison are needed to build a CVS checkout or if you changed the actual scanner and parser definition files. If you need them, be sure to get Flex 2.5.4 or later and Bison 1.875 or later. Other yacc programs can sometimes be used, but doing so requires extra effort and is not recommended. Other lex programs will definitely not work.

If you need to get a GNU package, you can find it at your local GNU mirror site (see <http://www.gnu.org/order/ftp.html> for a list) or at [ftp://ftp.gnu.org/gnu/](http://ftp.gnu.org/gnu/).

Also check that you have sufficient disk space. You will need about 65 MB for the source tree during compilation and about 15 MB for the installation directory. An empty database cluster takes about 25 MB, databases take about five times the amount of space that a flat text file with the same data would take. If you are going to run the regression tests you will temporarily need up to an extra 90 MB. Use the `df` command to check free disk space.

## 15.3. Getting The Source

The PostgreSQL 8.3.1 sources can be obtained by anonymous FTP from <ftp://ftp.postgresql.org/pub/source/v8.3.1/postgresql-8.3.1.tar.gz>. Other download options can be found on our website: <http://www.postgresql.org/download/>. After you have obtained the file, unpack it:

```
gunzip postgresql-8.3.1.tar.gz
tar xf postgresql-8.3.1.tar
```

This will create a directory `postgresql-8.3.1` under the current directory with the PostgreSQL sources. Change into that directory for the rest of the installation procedure.

## 15.4. Upgrading

These instructions assume that your existing installation is under the `/usr/local/pgsql` directory, and that the data area is in `/usr/local/pgsql/data`. Substitute your paths appropriately.

The internal data storage format typically changes in every major release of PostgreSQL. Therefore, if you are upgrading an existing installation that does not have a version number of “8.3.x”, you must back up and restore your data. If you are upgrading from PostgreSQL “8.3.x”, the new version can use your current data files so you should skip the backup and restore steps below because they are unnecessary.

1. If making a backup, make sure that your database is being updated. This does not affect the integrity of the backup, but the changed data would of course not be included. If necessary, edit the permissions in the file `/usr/local/pgsql/data/pg_hba.conf` (or equivalent) to disallow access from everyone except you.

To back up your database installation, type:

```
pg_dumpall > outputfile
```

If you need to preserve OIDs (such as when using them as foreign keys), then use the `-o` option when running `pg_dumpall`.

To make the backup, you can use the `pg_dumpall` command from the version you are currently running. For best results, however, try to use the `pg_dumpall` command from PostgreSQL 8.3.1, since this version contains bug fixes and improvements over older versions. While this advice might seem idiosyncratic since you haven't installed the new version yet, it is advisable to follow it if you plan to install the new version in parallel with the old version. In that case you can complete the installation normally and transfer the data later. This will also decrease the downtime.

2. Shut down the old server:

```
pg_ctl stop
```

On systems that have PostgreSQL started at boot time, there is probably a start-up file that will accomplish the same thing. For example, on a Red Hat Linux system one might find that

```
/etc/rc.d/init.d/postgresql stop  
works.
```

3. If restoring from backup, rename or delete the old installation directory. It is a good idea to rename the directory, rather than delete it, in case you have trouble and need to revert to it. Keep in mind the directory might consume significant disk space. To rename the directory, use a command like this:

```
mv /usr/local/pgsql /usr/local/pgsql.old
```

4. Install the new version of PostgreSQL as outlined in Section 15.5.
5. Create a new database cluster if needed. Remember that you must execute these commands while logged in to the special database user account (which you already have if you are upgrading).

```
/usr/local/pgsql/bin/initdb -D /usr/local/pgsql/data
```

6. Restore your previous `pg_hba.conf` and any `postgresql.conf` modifications.

7. Start the database server, again from the special database user account:

```
/usr/local/pgsql/bin/postgres -D /usr/local/pgsql/data
```

8. Finally, restore your data from backup with

```
/usr/local/pgsql/bin/psql -d postgres -f outputfile  
using the new psql.
```

Further discussion appears in Section 24.5, including instructions on how the previous installation can continue running while the new installation is installed.

## 15.5. Installation Procedure

### 1. Configuration

The first step of the installation procedure is to configure the source tree for your system and choose the options you would like. This is done by running the `configure` script. For a default installation simply enter

```
./configure
```

This script will run a number of tests to guess values for various system dependent variables and detect some quirks of your operating system, and finally will create several files in the build tree to record what it found. (You can also run `configure` in a directory outside the source tree if you want to keep the build directory separate.)

The default configuration will build the server and utilities, as well as all client applications and interfaces that require only a C compiler. All files will be installed under `/usr/local/pgsql` by default.

You can customize the build and installation process by supplying one or more of the following command line options to `configure`:

```
--prefix=PREFIX
```

Install all files under the directory `PREFIX` instead of `/usr/local/pgsql`. The actual files will be installed into various subdirectories; no files will ever be installed directly into the `PREFIX` directory.

If you have special needs, you can also customize the individual subdirectories with the following options. However, if you leave these with their defaults, the installation will be relocatable, meaning you can move the directory after installation. (The `man` and `doc` locations are not affected by this.)

For relocatable installs, you might want to use `configure`'s `--disable-rpath` option. Also, you will need to tell the operating system how to find the shared libraries.

```
--exec-prefix=EXEC-PREFIX
```

You can install architecture-dependent files under a different prefix, `EXEC-PREFIX`, than what `PREFIX` was set to. This can be useful to share architecture-independent files between hosts. If you omit this, then `EXEC-PREFIX` is set equal to `PREFIX` and both architecture-dependent and independent files will be installed under the same tree, which is probably what you want.

```
--bindir=DIRECTORY
```

Specifies the directory for executable programs. The default is `EXEC-PREFIX/bin`, which normally means `/usr/local/pgsql/bin`.

```
--datadir=DIRECTORY
```

Sets the directory for read-only data files used by the installed programs. The default is `PREFIX/share`. Note that this has nothing to do with where your database files will be placed.

```
--sysconfdir=DIRECTORY
```

The directory for various configuration files, `PREFIX/etc` by default.

`--libdir=DIRECTORY`

The location to install libraries and dynamically loadable modules. The default is `EXEC-PREFIX/lib`.

`--includedir=DIRECTORY`

The directory for installing C and C++ header files. The default is `PREFIX/include`.

`--mandir=DIRECTORY`

The man pages that come with PostgreSQL will be installed under this directory, in their respective `manx` subdirectories. The default is `PREFIX/man`.

`--with-docdir=DIRECTORY`

`--without-docdir`

Documentation files, except “man” pages, will be installed into this directory. The default is `PREFIX/doc`. If the option `--without-docdir` is specified, the documentation will not be installed by `make install`. This is intended for packaging scripts that have special methods for installing documentation.

**Note:** Care has been taken to make it possible to install PostgreSQL into shared installation locations (such as `/usr/local/include`) without interfering with the namespace of the rest of the system. First, the string “/postgresql” is automatically appended to `datadir`, `sysconfdir`, and `docdir`, unless the fully expanded directory name already contains the string “postgres” or “pgsql”. For example, if you choose `/usr/local` as prefix, the documentation will be installed in `/usr/local/doc/postgresql`, but if the prefix is `/opt/postgres`, then it will be in `/opt/postgres/doc`. The public C header files of the client interfaces are installed into `includedir` and are namespace-clean. The internal header files and the server header files are installed into private directories under `includedir`. See the documentation of each interface for information about how to get at the its header files. Finally, a private subdirectory will also be created, if appropriate, under `libdir` for dynamically loadable modules.

`--with-includes=DIRECTORIES`

`DIRECTORIES` is a colon-separated list of directories that will be added to the list the compiler searches for header files. If you have optional packages (such as GNU Readline) installed in a non-standard location, you have to use this option and probably also the corresponding `--with-libraries` option.

Example: `--with-includes=/opt/gnu/include:/usr/sup/include`.

`--with-libraries=DIRECTORIES`

`DIRECTORIES` is a colon-separated list of directories to search for libraries. You will probably have to use this option (and the corresponding `--with-includes` option) if you have packages installed in non-standard locations.

Example: `--with-libraries=/opt/gnu/lib:/usr/sup/lib`.

```
--enable-nls[=LANGUAGES]
```

Enables Native Language Support (NLS), that is, the ability to display a program's messages in a language other than English. *LANGUAGES* is a space-separated list of codes of the languages that you want supported, for example `--enable-nls='de fr'`. (The intersection between your list and the set of actually provided translations will be computed automatically.) If you do not specify a list, then all available translations are installed.

To use this option, you will need an implementation of the Gettext API; see above.

```
--with-pgport=NUMBER
```

Set *NUMBER* as the default port number for server and clients. The default is 5432. The port can always be changed later on, but if you specify it here then both server and clients will have the same default compiled in, which can be very convenient. Usually the only good reason to select a non-default value is if you intend to run multiple PostgreSQL servers on the same machine.

```
--with-perl
```

Build the PL/Perl server-side language.

```
--with-python
```

Build the PL/Python server-side language.

```
--with-tcl
```

Build the PL/Tcl server-side language.

```
--with-tclconfig=DIRECTORY
```

Tcl installs the file `tclConfig.sh`, which contains configuration information needed to build modules interfacing to Tcl. This file is normally found automatically at a well-known location, but if you want to use a different version of Tcl you can specify the directory in which to look for it.

```
--with-gssapi
```

Build with support for GSSAPI authentication. On many systems, the GSSAPI (usually a part of the Kerberos installation) system is not installed in a location that is searched by default (e.g., `/usr/include`, `/usr/lib`), so you must use the options `--with-includes` and `--with-libraries` in addition to this option. `configure` will check for the required header files and libraries to make sure that your GSSAPI installation is sufficient before proceeding.

```
--with-krb5
```

Build with support for Kerberos 5 authentication. On many systems, the Kerberos system is not installed in a location that is searched by default (e.g., `/usr/include`, `/usr/lib`), so you must use the options `--with-includes` and `--with-libraries` in addition to this option. `configure` will check for the required header files and libraries to make sure that your Kerberos installation is sufficient before proceeding.

```
--with-krb-srvnam=NAME
```

The default name of the Kerberos service principal (also used by GSSAPI). `postgres` is the default. There's usually no reason to change this unless you have a Windows environment, in which case it must be set to uppercase `POSTGRES`.

`--with-openssl`

Build with support for SSL (encrypted) connections. This requires the OpenSSL package to be installed. `configure` will check for the required header files and libraries to make sure that your OpenSSL installation is sufficient before proceeding.

`--with-pam`

Build with PAM (Pluggable Authentication Modules) support.

`--with-ldap`

Build with LDAP support for authentication and connection parameter lookup (see Section 30.15 and Section 21.2.7 for more information). On Unix, this requires the OpenLDAP package to be installed. `configure` will check for the required header files and libraries to make sure that your OpenLDAP installation is sufficient before proceeding. On Windows, the default WinLDAP library is used.

`--without-readline`

Prevents use of the Readline library (and libedit as well). This option disables command-line editing and history in `psql`, so it is not recommended.

`--with-libedit-preferred`

Favors the use of the BSD-licensed libedit library rather than GPL-licensed Readline. This option is significant only if you have both libraries installed; the default in that case is to use Readline.

`--with-bonjour`

Build with Bonjour support. This requires Bonjour support in your operating system. Recommended on Mac OS X.

`--with-ossdp-uuid`

Use the OSSP UUID library<sup>1</sup> when building `contrib/uuid-ossdp`. The library provides functions to generate UUIDs.

`--with-libxml`

Build with libxml (enables SQL/XML support). Libxml version 2.6.23 or later is required for this feature.

Libxml installs a program `xml2-config` that can be used to detect the required compiler and linker options. PostgreSQL will use it automatically if found. To specify a libxml installation at an unusual location, you can either set the environment variable `XML2_CONFIG` to point to the `xml2-config` program belonging to the installation, or use the options `--with-includes` and `--with-libraries`.

`--with-libxslt`

Use libxslt when building `contrib/xml2`. `contrib/xml2` relies on this library to perform XSL transformations of XML.

---

1. <http://www.ossdp.org/pkg/lib/uuid/>

`--enable-integer-datetimes`

Use 64-bit integer storage for datetimes and intervals, rather than the default floating-point storage. This reduces the range of representable values but guarantees microsecond precision across the full range (see Section 8.5 for more information).

`--disable-spinlocks`

Allow the build to succeed even if PostgreSQL has no CPU spinlock support for the platform. The lack of spinlock support will result in poor performance; therefore, this option should only be used if the build aborts and informs you that the platform lacks spinlock support. If this option is required to build PostgreSQL on your platform, please report the problem to the PostgreSQL developers.

`--enable-thread-safety`

Make the client libraries thread-safe. This allows concurrent threads in libpq and ECPG programs to safely control their private connection handles. This option requires adequate threading support in your operating system.

`--with-system-tzdata=DIRECTORY`

PostgreSQL includes its own time zone database, which it requires for date and time operations. This time zone database is in fact compatible with the “zic” time zone database provided by many operating systems such as FreeBSD, Linux, and Solaris, so it would be redundant to install it again. When this option is used, the system-supplied time zone database in *DIRECTORY* is used instead of the one included in the PostgreSQL source distribution. *DIRECTORY* must be specified as an absolute path. */usr/share/zoneinfo* is a likely directory on some operating systems. Note that the installation routine will not detect mismatching or erroneous time zone data. If you use this option, you are advised to run the regression tests to verify that the time zone data you have pointed to works correctly with PostgreSQL.

This option is mainly aimed at binary package distributors who know their target operating system well. The main advantage of using this option is that the PostgreSQL package won’t need to be upgraded whenever any of the many local daylight-saving time rules change. Another advantage is that PostgreSQL can be cross-compiled more straightforwardly if the time zone database files do not need to be built during the installation.

`--without-zlib`

Prevents use of the Zlib library. This disables support for compressed archives in *pg\_dump* and *pg\_restore*. This option is only intended for those rare systems where this library is not available.

`--enable-debug`

Compiles all programs and libraries with debugging symbols. This means that you can run the programs through a debugger to analyze problems. This enlarges the size of the installed executables considerably, and on non-GCC compilers it usually also disables compiler optimization, causing slowdowns. However, having the symbols available is extremely helpful for dealing with any problems that might arise. Currently, this option is recommended for production installations only if you use GCC. But you should always have it on if you are doing development work or running a beta version.

`--enable-profiling`

If using GCC, all programs and libraries are compiled so they can be profiled. On backend exit,

a subdirectory will be created that contains the `gmon.out` file for use in profiling. This option is for use only with GCC and when doing development work.

`--enable-cassert`

Enables *assertion* checks in the server, which test for many “cannot happen” conditions. This is invaluable for code development purposes, but the tests can slow down the server significantly. Also, having the tests turned on won’t necessarily enhance the stability of your server! The assertion checks are not categorized for severity, and so what might be a relatively harmless bug will still lead to server restarts if it triggers an assertion failure. This option is not recommended for production use, but you should have it on for development work or when running a beta version.

`--enable-depend`

Enables automatic dependency tracking. With this option, the makefiles are set up so that all affected object files will be rebuilt when any header file is changed. This is useful if you are doing development work, but is just wasted overhead if you intend only to compile once and install. At present, this option will work only if you use GCC.

`--enable-dtrace`

Compiles with support for the dynamic tracing tool DTrace. Operating system support for DTrace is currently only available in Solaris.

To point to the `dtrace` program, the environment variable `DTRACE` can be set. This will often be necessary because `dtrace` is typically installed under `/usr/sbin`, which might not be in the path. Additional command-line options for the `dtrace` program can be specified in the environment variable `DTRACEFLAGS`.

To include DTrace support in a 64-bit binary, specify `DTRACEFLAGS="-64"` to configure. For example, using the GCC compiler:

```
./configure CC='gcc -m64' --enable-dtrace DTRACEFLAGS='-64' ...
```

Using Sun’s compiler:

```
./configure CC='/opt/SUNWspro/bin/cc -xtarget=native64' --enable-dtrace DTRACEFLAGS=
```

If you prefer a C compiler different from the one `configure` picks, you can set the environment variable `CC` to the program of your choice. By default, `configure` will pick `gcc` if available, else the platform’s default (usually `cc`). Similarly, you can override the default compiler flags if needed with the `CFLAGS` variable.

You can specify environment variables on the `configure` command line, for example:

```
./configure CC=/opt/bin/gcc CFLAGS='-O2 -pipe'
```

Here is a list of the significant variables that can be set in this manner:

`CC`

C compiler

`CFLAGS`

options to pass to the C compiler

CPP

C preprocessor

CPPFLAGS

options to pass to the C preprocessor

DTRACE

location of the `dtrace` program

DTRACEFLAGS

options to pass to the `dtrace` program

LDFLAGS

options to pass to the link editor

LDFLAGS\_SL

linker options for shared library linking

MSGFMT

`msgfmt` program for native language support

PERL

Full path to the Perl interpreter. This will be used to determine the dependencies for building PL/Perl.

PYTHON

Full path to the Python interpreter. This will be used to determine the dependencies for building PL/Python.

TCLSH

Full path to the Tcl interpreter. This will be used to determine the dependencies for building PL/Tcl.

XML2\_CONFIG

`xml2-config` program used to locate the libxml installation.

YACC

Yacc program (`bison -y` if using Bison)

## 2. Build

To start the build, type

**gmake**

(Remember to use GNU make.) The build will take a few minutes depending on your hardware. The last line displayed should be

All of PostgreSQL is successfully made. Ready to install.

## 3. Regression Tests

If you want to test the newly built server before you install it, you can run the regression tests at this point. The regression tests are a test suite to verify that PostgreSQL runs on your machine in the way the developers expected it to. Type

```
gmake check
```

(This won't work as root; do it as an unprivileged user.) Chapter 29 contains detailed information about interpreting the test results. You can repeat this test at any later time by issuing the same command.

#### 4. Installing The Files

**Note:** If you are upgrading an existing system and are going to install the new files over the old ones, be sure to back up your data and shut down the old server before proceeding, as explained in Section 15.4 above.

To install PostgreSQL enter

```
gmake install
```

This will install files into the directories that were specified in step 1. Make sure that you have appropriate permissions to write into that area. Normally you need to do this step as root. Alternatively, you could create the target directories in advance and arrange for appropriate permissions to be granted.

You can use `gmake install-strip` instead of `gmake install` to strip the executable files and libraries as they are installed. This will save some space. If you built with debugging support, stripping will effectively remove the debugging support, so it should only be done if debugging is no longer needed. `install-strip` tries to do a reasonable job saving space, but it does not have perfect knowledge of how to strip every unneeded byte from an executable file, so if you want to save all the disk space you possibly can, you will have to do manual work.

The standard installation provides all the header files needed for client application development as well as for server-side program development, such as custom functions or data types written in C. (Prior to PostgreSQL 8.0, a separate `gmake install-all-headers` command was needed for the latter, but this step has been folded into the standard install.)

**Client-only installation:** If you want to install only the client applications and interface libraries, then you can use these commands:

```
gmake -C src/bin install
gmake -C src/include install
gmake -C src/interfaces install
gmake -C doc install
```

`src/bin` has a few binaries for server-only use, but they are small.

**Registering eventlog on Windows:** To register a Windows eventlog library with the operating system, issue this command after installation:

```
regsvr32 pgsqllibrary_directory/pgevent.dll
```

This creates registry entries used by the event viewer.

**Uninstallation:** To undo the installation use the command `gmake uninstall`. However, this will not remove any created directories.

**Cleaning:** After the installation you can make room by removing the built files from the source tree with the command `gmake clean`. This will preserve the files made by the `configure` program, so that you can rebuild everything with `gmake` later on. To reset the source tree to the state in which it was distributed, use `gmake distclean`. If you are going to build for several platforms within the same source tree you must do this and re-configure for each build. (Alternatively, use a separate build tree for each platform, so that the source tree remains unmodified.)

If you perform a build and then discover that your `configure` options were wrong, or if you change anything that `configure` investigates (for example, software upgrades), then it's a good idea to do `gmake distclean` before reconfiguring and rebuilding. Without this, your changes in configuration choices might not propagate everywhere they need to.

## 15.6. Post-Installation Setup

### 15.6.1. Shared Libraries

On some systems that have shared libraries (which most systems do) you need to tell your system how to find the newly installed shared libraries. The systems on which this is *not* necessary include BSD/OS, FreeBSD, HP-UX, IRIX, Linux, NetBSD, OpenBSD, Tru64 UNIX (formerly Digital UNIX), and Solaris.

The method to set the shared library search path varies between platforms, but the most widely usable method is to set the environment variable `LD_LIBRARY_PATH` like so: In Bourne shells (`sh`, `ksh`, `bash`, `zsh`):

```
LD_LIBRARY_PATH=/usr/local/pgsql/lib
export LD_LIBRARY_PATH
```

or in `csh` or `tcsh`:

```
setenv LD_LIBRARY_PATH /usr/local/pgsql/lib
```

Replace `/usr/local/pgsql/lib` with whatever you set `--libdir` to in step 1. You should put these commands into a shell start-up file such as `/etc/profile` or `~/.bash_profile`. Some good information about the caveats associated with this method can be found at <http://www.visi.com/~barr/ldpath.html>.

On some systems it might be preferable to set the environment variable `LD_RUN_PATH` *before* building.

On Cygwin, put the library directory in the `PATH` or move the `.dll` files into the `bin` directory.

If in doubt, refer to the manual pages of your system (perhaps `ld.so` or `rld`). If you later on get a message like

```
psql: error in loading shared libraries
libpq.so.2.1: cannot open shared object file: No such file or directory
```

then this step was necessary. Simply take care of it then.

If you are on BSD/OS, Linux, or SunOS 4 and you have root access you can run:

```
/sbin/ldconfig /usr/local/pgsql/lib
```

(or equivalent directory) after installation to enable the run-time linker to find the shared libraries faster. Refer to the manual page of `ldconfig` for more information. On FreeBSD, NetBSD, and OpenBSD the command is:

```
/sbin/ldconfig -m /usr/local/pgsql/lib
```

instead. Other systems are not known to have an equivalent command.

## 15.6.2. Environment Variables

If you installed into `/usr/local/pgsql` or some other location that is not searched for programs by default, you should add `/usr/local/pgsql/bin` (or whatever you set `--bindir` to in step 1) into your `PATH`. Strictly speaking, this is not necessary, but it will make the use of PostgreSQL much more convenient.

To do this, add the following to your shell start-up file, such as `~/.bash_profile` (or `/etc/profile`, if you want it to affect every user):

```
PATH=/usr/local/pgsql/bin:$PATH
export PATH
```

If you are using `csh` or `tcsh`, then use this command:

```
set path = ( /usr/local/pgsql/bin $path )
```

To enable your system to find the man documentation, you need to add lines like the following to a shell start-up file unless you installed into a location that is searched by default:

```
MANPATH=/usr/local/pgsql/man:$MANPATH
export MANPATH
```

The environment variables `PGHOST` and `PGPORT` specify to client applications the host and port of the database server, overriding the compiled-in defaults. If you are going to run client applications remotely then it is convenient if every user that plans to use the database sets `PGHOST`. This is not required, however: the settings can be communicated via command line options to most client programs.

## 15.7. Supported Platforms

A platform (that is, a CPU architecture and operating system combination) is considered supported by the PostgreSQL development community if the code contains provisions to work on that platform and it has recently been verified to build and pass its regression tests on that platform. Currently, most testing of platform compatibility is done automatically by test machines in the PostgreSQL Build Farm<sup>2</sup>. If you are interested in using PostgreSQL on a platform that is not represented in the build farm, but on which the

---

2. <http://buildfarm.postgresql.org/>

code works or can be made to work, you are strongly encouraged to set up a build farm member machine so that continued compatibility can be assured.

In general, PostgreSQL can be expected to work on these CPU architectures: x86, x86\_64, IA64, PowerPC, PowerPC 64, S/390, S/390x, Sparc, Sparc 64, Alpha, ARM, MIPS, MIPSEL, M68K, and PA-RISC. Code support exists for M32R, NS32K, and VAX, but these architectures are not known to have been tested recently. It is often possible to build on an unsupported CPU type by configuring with `--disable-spinlocks`, but performance will be poor.

PostgreSQL can be expected to work on these operating systems: Linux (all recent distributions), Windows (Win2000 SP4 and later), FreeBSD, OpenBSD, NetBSD, Mac OS X, AIX, HP/UX, IRIX, Solaris, Tru64 Unix, and UnixWare. Other Unix-like systems may also work but are not currently being tested. In most cases, all CPU architectures supported by a given operating system will work. Look in the `doc/` directory of the source distribution to see if there is a FAQ document specific to your operating system, particularly if using an older system.

If you have installation problems on a platform that is known to be supported according to recent build farm results, please report it to [<pgsql-bugs@postgresql.org>](mailto:pgsql-bugs@postgresql.org). If you are interested in porting PostgreSQL to a new platform, [<pgsql-ports@postgresql.org>](mailto:pgsql-ports@postgresql.org) is the appropriate place to discuss that.

# Chapter 16. Installation on Windows

It is recommended that most users download the binary distribution for Windows, available as a Windows Installer package from the PostgreSQL website. Building from source is only intended for people developing PostgreSQL or extensions.

There are several different ways of building PostgreSQL on Windows. The complete system can be built using MinGW or Visual C++ 2005. It can also be built for older versions of Windows using Cygwin. Finally, the client access library (libpq) can be built using Visual C++ 7.1 or Borland C++ for compatibility with statically linked applications built using these tools.

Building using MinGW or Cygwin uses the normal build system, see Chapter 15 and the FAQs in `doc/FAQ_MINGW` and `doc/FAQ_CYGWIN`. Note that Cygwin is not recommended, and should only be used for older versions of Windows where the native build does not work, such as Windows 98.

## 16.1. Building with Visual C++ 2005

The tools for building using Visual C++ 2005, are in the `src/tools/msvc` directory. When building, make sure there are no tools from MinGW or Cygwin present in your system PATH. Also, make sure you have all the required Visual C++ tools available in the PATH, usually by starting a Visual Studio Command Prompt and running the commands from there. All commands should be run from the `src/tools/msvc` directory.

Before you build, edit the file `config.pl` to reflect the configuration options you want set, including the paths to libraries used. If you need to set any other environment variables, create a file called `buildenv.pl` and put the required commands there. For example, to add the path for bison when it's not in the PATH, create a file containing:

```
$ENV{PATH}=$ENV{PATH} . 'c:\some\where\bison\bin';
```

### 16.1.1. Requirements

PostgreSQL will build using either the professional versions (any edition) or the free Express edition of Visual Studio 2005. The following additional products are required to build the complete package. Use the `config.pl` to specify which directories the libraries are available in.

#### ActiveState Perl

ActiveState Perl is required to run the build generation scripts. MinGW or Cygwin Perl will not work. It must also be present in the PATH. Binaries can be downloaded from <http://www.activestate.com>.

#### ActiveState TCL

Required for building PL/TCL.

#### Bison and Flex

Bison and Flex are required to build from CVS, but not required when building from a release file. Note that only Bison 1.875 or versions 2.2 and later will work. Bison and Flex can be downloaded from <http://gnuwin32.sourceforge.net>.

#### Diff

Diff is required to run the regression tests, and can be downloaded from <http://gnuwin32.sourceforge.net>.

#### Gettext

Gettext is required to build with NLS support, and can be downloaded from <http://gnuwin32.sourceforge.net>. Note that binaries, dependencies and developer files are all needed.

#### Microsoft Platform SDK

It is recommended that you upgrade to the latest available version of the Microsoft Platform SDK, available for download from <http://www.microsoft.com/downloads/>.

#### MIT Kerberos

Required for Kerberos authentication support. MIT Kerberos can be downloaded from <http://web.mit.edu/Kerberos/dist/index.html>.

#### libxml2 and libxslt

Required for XML support. Binaries can be downloaded from <http://zlatkovic.com/pub/libxml> or source from <http://xmlsoft.org>. Note that libxml2 requires iconv, which is available from the same download location.

#### openssl

Required for SSL support. Binaries can be downloaded from <http://www.slproweb.com/products/Win32OpenSSL.html> or source from <http://www.openssl.org>.

#### ossp-uuid

Required for UUID-OSSP support (contrib only). Source can be downloaded from <http://www.ossp.org/pkg/lib/uuid/>.

#### Python

Required for building PL/Python. Binaries can be downloaded from <http://www.python.org>.

#### zlib

Required for compression support in pg\_dump and pg\_restore. Binaries can be downloaded from <http://www.zlib.net>.

## 16.1.2. Building

To build all of PostgreSQL in release configuration (the default), run the command:

```
build
```

To build all of PostgreSQL in debug configuration, run the command:

```
build DEBUG
```

To build just a single project, for example `psql`, run the commands:

```
build psql
```

```
build DEBUG psql
```

To change the default build configuration to debug, put the following in the `buildenv.pl` file:

```
$ENV{CONFIG}="Debug";
```

It is also possible to build from inside the Visual Studio GUI. In this case, you need to run:

```
perl mkvcbuild.pl
```

from the command prompt, and then open the generated `pgsql.sln` (in the root directory of the source tree) in Visual Studio.

### 16.1.3. Cleaning and installing

Most of the time, the automatic dependency tracking in Visual Studio will handle changed files. But if there have been large changes, you may need to clean the installation. To do this, simply run the `clean.bat` command, which will automatically clean out all generated files. You can also run it with the `dist` parameter, in which case it will behave like `make distclean` and remove the flex/bison output files as well.

By default, all files are written into a subdirectory of the `debug` or `release` directories. To install these files using the standard layout, and also generate the files required to initialize and use the database, run the command:

```
perl install.pl c:\destination\directory
```

### 16.1.4. Running the regression tests

To run the regression tests, make sure you have completed the build of all required parts first. Also, make sure that the DLLs required to load all parts of the system (such as the Perl and Python DLLs for the procedural languages) are present in the system path. If they are not, set it through the `buildenv.pl` file. To run the tests, run one of the following commands from the `src\tools\msvc` directory:

```
vc regress check

vc regress installcheck

vc regress plcheck

vc regress contribcheck
```

To change the schedule used (default is the parallel), append it to the command line like:

```
vc regress check serial
```

For more information about the regression tests, see Chapter 29.

### 16.1.5. Building the documentation

Building the PostgreSQL documentation in HTML format requires several tools and files. Create a root directory for all these files, and store them in the subdirectories in the list below.

#### OpenJade 1.3.1-2

Download from [http://sourceforge.net/project/downloading.php?groupname=openjade&filename=openjade-1\\_3\\_1-2-bin.zip](http://sourceforge.net/project/downloading.php?groupname=openjade&filename=openjade-1_3_1-2-bin.zip) and uncompress in the subdirectory `openjade-1.3.1`.

#### DocBook DTD 4.2

Download from <http://www.oasis-open.org/docbook/sgml/4.2/docbook-4.2.zip> and uncompress in the subdirectory `docbook`.

#### DocBook DSSSL 1.79

Download from <http://sourceforge.net/project/downloading.php?groupname=docbook&filename=docbook-dsssl-1.79.zip> and uncompress in the subdirectory `docbook-dsssl-1.79`.

#### ISO character entities

Download from <http://www.oasis-open.org/cover/ISOEnts.zip> and uncompress in the subdirectory `docbook`.

Edit the `buildenv.pl` file, and add a variable for the location of the root directory, for example:

```
$ENV{DOCR00T}='c:\docbook';
```

To build the documentation, run the command `bulddoc.bat`. Note that this will actually run the build twice, in order to generate the indexes. The generated HTML files will be in `doc\src\sgml`.

## 16.2. Building libpq with Visual C++ or Borland C++

Using Visual C++ 7.1-8.0 or Borland C++ to build libpq is only recommended if you need a version with different debug/release flags, or if you need a static library to link into an application. For normal use the MinGW or Visual Studio 2005 version is recommended.

To build the libpq client library using Visual Studio 7.1 or later, change into the `src` directory and type the command

```
nmake /f win32.mak
```

To build a 64-bit version of the libpq client library using Visual Studio 8.0 or later, change into the `src` directory and type in the command

```
nmake /f win32.mak CPU=AMD64
```

See the `win32.mak` file for further details about supported variables.

To build the libpq client library using Borland C++, change into the `src` directory and type the command

```
make -N -DCFG=Release /f bcc32.mak
```

### 16.2.1. Generated files

The following files will be built:

```
interfaces\libpq\Release\libpq.dll
```

The dynamically linkable frontend library

```
interfaces\libpq\Release\libpqdll.lib
```

Import library to link your programs to `libpq.dll`

```
interfaces\libpq\Release\libpq.lib
```

Static version of the frontend library

Normally you do not need to install any of the client files. You should place the `libpq.dll` file in the same directory as your applications executable file. Do not install `libpq.dll` into your Windows, System or System32 directory unless absolutely necessary. If this file is installed using a setup program, it should be installed with version checking using the `VERSIONINFO` resource included in the file, to ensure that a newer version of the library is not overwritten.

If you are planning to do development using libpq on this machine, you will have to add the `src\include` and `src\interfaces\libpq` subdirectories of the source tree to the include path in your compiler's settings.

To use the library, you must add the `libpqdll.lib` file to your project. (In Visual C++, just right-click on the project and choose to add it.)

# Chapter 17. Operating System Environment

This chapter discusses how to set up and run the database server and its interactions with the operating system.

## 17.1. The PostgreSQL User Account

As with any other server daemon that is accessible to the outside world, it is advisable to run PostgreSQL under a separate user account. This user account should only own the data that is managed by the server, and should not be shared with other daemons. (For example, using the user `nobody` is a bad idea.) It is not advisable to install executables owned by this user because compromised systems could then modify their own binaries.

To add a Unix user account to your system, look for a command `useradd` or `adduser`. The user name `postgres` is often used, and is assumed throughout this book, but you can use another name if you like.

## 17.2. Creating a Database Cluster

Before you can do anything, you must initialize a database storage area on disk. We call this a *database cluster*. (SQL uses the term *catalog cluster*.) A database cluster is a collection of databases that is managed by a single instance of a running database server. After initialization, a database cluster will contain a database named `postgres`, which is meant as a default database for use by utilities, users and third party applications. The database server itself does not require the `postgres` database to exist, but many external utility programs assume it exists. Another database created within each cluster during initialization is called `template1`. As the name suggests, this will be used as a template for subsequently created databases; it should not be used for actual work. (See Chapter 20 for information about creating new databases within a cluster.)

In file system terms, a database cluster will be a single directory under which all data will be stored. We call this the *data directory* or *data area*. It is completely up to you where you choose to store your data. There is no default, although locations such as `/usr/local/pgsql/data` or `/var/lib/pgsql/data` are popular. To initialize a database cluster, use the command `initdb`, which is installed with PostgreSQL. The desired file system location of your database cluster is indicated by the `-D` option, for example

```
$ initdb -D /usr/local/pgsql/data
```

Note that you must execute this command while logged into the PostgreSQL user account, which is described in the previous section.

**Tip:** As an alternative to the `-D` option, you can set the environment variable `PGDATA`.

`initdb` will attempt to create the directory you specify if it does not already exist. It is likely that it will not have the permission to do so (if you followed our advice and created an unprivileged account). In that case you should create the directory yourself (as root) and change the owner to be the PostgreSQL user. Here is how this might be done:

```

root# mkdir /usr/local/pgsql/data
root# chown postgres /usr/local/pgsql/data
root# su postgres
postgres$ initdb -D /usr/local/pgsql/data

```

`initdb` will refuse to run if the data directory looks like it has already been initialized.

Because the data directory contains all the data stored in the database, it is essential that it be secured from unauthorized access. `initdb` therefore revokes access permissions from everyone but the PostgreSQL user.

However, while the directory contents are secure, the default client authentication setup allows any local user to connect to the database and even become the database superuser. If you do not trust other local users, we recommend you use one of `initdb`'s `-W`, `--pwprompt` or `--pwfile` options to assign a password to the database superuser. Also, specify `-A md5` or `-A password` so that the default `trust` authentication mode is not used; or modify the generated `pg_hba.conf` file after running `initdb`, *before* you start the server for the first time. (Other reasonable approaches include using `ident` authentication or file system permissions to restrict connections. See Chapter 21 for more information.)

`initdb` also initializes the default locale for the database cluster. Normally, it will just take the locale settings in the environment and apply them to the initialized database. It is possible to specify a different locale for the database; more information about that can be found in Section 22.1. The sort order used within a particular database cluster is set by `initdb` and cannot be changed later, short of dumping all data, rerunning `initdb`, and reloading the data. There is also a performance impact for using locales other than `C` or `POSIX`. Therefore, it is important to make this choice correctly the first time.

`initdb` also sets the default character set encoding for the database cluster. Normally this should be chosen to match the locale setting. For details see Section 22.2.

### 17.2.1. Network File Systems

Many installations create database clusters on network file systems. Sometimes this is done directly via NFS, or by using a Network Attached Storage (NAS) device that uses NFS internally. PostgreSQL does nothing special for NFS file systems, meaning it assumes NFS behaves exactly like locally-connected drives (DAS, Direct Attached Storage). If client and server NFS implementations have non-standard semantics, this can cause reliability problems (see [http://www.time-travellers.org/shane/papers/NFS\\_considered\\_harmful.html](http://www.time-travellers.org/shane/papers/NFS_considered_harmful.html)). Specifically, delayed (asynchronous) writes to the NFS server can cause reliability problems; if possible, mount NFS file systems synchronously (without caching) to avoid this. (Storage Area Networks (SAN) use a low-level communication protocol rather than NFS.)

## 17.3. Starting the Database Server

Before anyone can access the database, you must start the database server. The database server program is called `postgres`. The `postgres` program must know where to find the data it is supposed to use. This

is done with the `-D` option. Thus, the simplest way to start the server is:

```
$ postgres -D /usr/local/pgsql/data
```

which will leave the server running in the foreground. This must be done while logged into the PostgreSQL user account. Without `-D`, the server will try to use the data directory named by the environment variable `PGDATA`. If that variable is not provided either, it will fail.

Normally it is better to start `postgres` in the background. For this, use the usual shell syntax:

```
$ postgres -D /usr/local/pgsql/data >logfile 2>&1 &
```

It is important to store the server's stdout and stderr output somewhere, as shown above. It will help for auditing purposes and to diagnose problems. (See Section 23.3 for a more thorough discussion of log file handling.)

The `postgres` program also takes a number of other command-line options. For more information, see the `postgres` reference page and Chapter 18 below.

This shell syntax can get tedious quickly. Therefore the wrapper program `pg_ctl` is provided to simplify some tasks. For example:

```
pg_ctl start -l logfile
```

will start the server in the background and put the output into the named log file. The `-D` option has the same meaning here as for `postgres`. `pg_ctl` is also capable of stopping the server.

Normally, you will want to start the database server when the computer boots. Autostart scripts are operating-system-specific. There are a few distributed with PostgreSQL in the `contrib/start-scripts` directory. Installing one will require root privileges.

Different systems have different conventions for starting up daemons at boot time. Many systems have a file `/etc/rc.local` or `/etc/rc.d/rc.local`. Others use `rc.d` directories. Whatever you do, the server must be run by the PostgreSQL user account *and not by root* or any other user. Therefore you probably should form your commands using `su -c '...' postgres`. For example:

```
su -c 'pg_ctl start -D /usr/local/pgsql/data -l serverlog' postgres
```

Here are a few more operating-system-specific suggestions. (In each case be sure to use the proper installation directory and user name where we show generic values.)

- For FreeBSD, look at the file `contrib/start-scripts/freebsd` in the PostgreSQL source distribution.
- On OpenBSD, add the following lines to the file `/etc/rc.local`:  

```
if [ -x /usr/local/pgsql/bin/pg_ctl -a -x /usr/local/pgsql/bin/postgres ]; then
    su - -c '/usr/local/pgsql/bin/pg_ctl start -l /var/postgresql/log -s' postgres
    echo -n ' postgresql'
fi
```
- On Linux systems either add  

```
/usr/local/pgsql/bin/pg_ctl start -l logfile -D /usr/local/pgsql/data
```

to `/etc/rc.d/rc.local` or look at the file `contrib/start-scripts/linux` in the PostgreSQL source distribution.

- On NetBSD, either use the FreeBSD or Linux start scripts, depending on preference.
- On Solaris, create a file called `/etc/init.d/postgresql` that contains the following line:

```
su - postgres -c "/usr/local/pgsql/bin/pg_ctl start -l logfile -D /usr/local/pgsql/data"
Then, create a symbolic link to it in /etc/rc3.d as S99postgresql.
```

While the server is running, its PID is stored in the file `postmaster.pid` in the data directory. This is used to prevent multiple server instances from running in the same data directory and can also be used for shutting down the server.

### 17.3.1. Server Start-up Failures

There are several common reasons the server might fail to start. Check the server's log file, or start it by hand (without redirecting standard output or standard error) and see what error messages appear. Below we explain some of the most common error messages in more detail.

```
LOG:  could not bind IPv4 socket: Address already in use
HINT:  Is another postmaster already running on port 5432? If not, wait a few seconds and re
FATAL:  could not create TCP/IP listen socket
```

This usually means just what it suggests: you tried to start another server on the same port where one is already running. However, if the kernel error message is not `Address already in use` or some variant of that, there might be a different problem. For example, trying to start a server on a reserved port number might draw something like:

```
$ postgres -p 666
LOG:  could not bind IPv4 socket: Permission denied
HINT:  Is another postmaster already running on port 666? If not, wait a few seconds and re
FATAL:  could not create TCP/IP listen socket
```

A message like

```
FATAL:  could not create shared memory segment: Invalid argument
DETAIL:  Failed system call was shmget(key=5440001, size=4011376640, 03600).
```

probably means your kernel's limit on the size of shared memory is smaller than the work area PostgreSQL is trying to create (4011376640 bytes in this example). Or it could mean that you do not have System-V-style shared memory support configured into your kernel at all. As a temporary workaround, you can try starting the server with a smaller-than-normal number of buffers (`shared_buffers`). You will eventually want to reconfigure your kernel to increase the allowed shared memory size. You might also see this message when trying to start multiple servers on the same machine, if their total space requested exceeds the kernel limit.

An error like

```
FATAL:  could not create semaphores: No space left on device
```

DETAIL: Failed system call was semget(5440126, 17, 03600).

does *not* mean you’ve run out of disk space. It means your kernel’s limit on the number of System V semaphores is smaller than the number PostgreSQL wants to create. As above, you might be able to work around the problem by starting the server with a reduced number of allowed connections (`max_connections`), but you’ll eventually want to increase the kernel limit.

If you get an “illegal system call” error, it is likely that shared memory or semaphores are not supported in your kernel at all. In that case your only option is to reconfigure the kernel to enable these features.

Details about configuring System V IPC facilities are given in Section 17.4.1.

### 17.3.2. Client Connection Problems

Although the error conditions possible on the client side are quite varied and application-dependent, a few of them might be directly related to how the server was started up. Conditions other than those shown below should be documented with the respective client application.

```
psql: could not connect to server: Connection refused
        Is the server running on host "server.joe.com" and accepting
        TCP/IP connections on port 5432?
```

This is the generic “I couldn’t find a server to talk to” failure. It looks like the above when TCP/IP communication is attempted. A common mistake is to forget to configure the server to allow TCP/IP connections.

Alternatively, you’ll get this when attempting Unix-domain socket communication to a local server:

```
psql: could not connect to server: No such file or directory
        Is the server running locally and accepting
        connections on Unix domain socket "/tmp/.s.PGSQL.5432"?
```

The last line is useful in verifying that the client is trying to connect to the right place. If there is in fact no server running there, the kernel error message will typically be either `Connection refused` or `No such file or directory`, as illustrated. (It is important to realize that `Connection refused` in this context does *not* mean that the server got your connection request and rejected it. That case will produce a different message, as shown in Section 21.3.) Other error messages such as `Connection timed out` might indicate more fundamental problems, like lack of network connectivity.

## 17.4. Managing Kernel Resources

A large PostgreSQL installation can quickly exhaust various operating system resource limits. (On some systems, the factory defaults are so low that you don’t even need a really “large” installation.) If you have encountered this kind of problem, keep reading.

## 17.4.1. Shared Memory and Semaphores

Shared memory and semaphores are collectively referred to as “System V IPC” (together with message queues, which are not relevant for PostgreSQL). Almost all modern operating systems provide these features, but not all of them have them turned on or sufficiently sized by default, especially systems with BSD heritage. (On Windows, PostgreSQL provides its own replacement implementation of these facilities, and so most of this section can be disregarded.)

The complete lack of these facilities is usually manifested by an Illegal system call error upon server start. In that case there’s nothing left to do but to reconfigure your kernel. PostgreSQL won’t work without them.

When PostgreSQL exceeds one of the various hard IPC limits, the server will refuse to start and should leave an instructive error message describing the problem encountered and what to do about it. (See also Section 17.3.1.) The relevant kernel parameters are named consistently across different systems; Table 17-1 gives an overview. The methods to set them, however, vary. Suggestions for some platforms are given below. Be warned that it is often necessary to reboot your machine, and possibly even recompile the kernel, to change these settings.

**Table 17-1. System V IPC parameters**

Name	Description	Reasonable values
SHMMAX	Maximum size of shared memory segment (bytes)	at least several megabytes (see text)
SHMMIN	Minimum size of shared memory segment (bytes)	1
SHMALL	Total amount of shared memory available (bytes or pages)	if bytes, same as SHMMAX; if pages, <code>ceil (SHMMAX/PAGE_SIZE)</code>
SHMSEG	Maximum number of shared memory segments per process	only 1 segment is needed, but the default is much higher
SHMMNI	Maximum number of shared memory segments system-wide	like SHMSEG plus room for other applications
SEMMNI	Maximum number of semaphore identifiers (i.e., sets)	at least <code>ceil ( (max_connections + autovacuum_max_workers) / 16 )</code>
SEMMNS	Maximum number of semaphores system-wide	<code>ceil ( (max_connections + autovacuum_max_workers) / 16 ) * 17</code> plus room for other applications
SEMMSL	Maximum number of semaphores per set	at least 17
SEMAP	Number of entries in semaphore map	see text

Name	Description	Reasonable values
SEMMVMX	Maximum value of semaphore	at least 1000 (The default is often 32767, don't change unless forced to)

The most important shared memory parameter is `SHMMAX`, the maximum size, in bytes, of a shared memory segment. If you get an error message from `shmget` like `Invalid argument`, it is likely that this limit has been exceeded. The size of the required shared memory segment varies depending on several PostgreSQL configuration parameters, as shown in Table 17-2. (Any error message you might get will include the exact size of the failed allocation request.) You can, as a temporary solution, lower some of those settings to avoid the failure. While it is possible to get PostgreSQL to run with `SHMMAX` as small as 2 MB, you need considerably more for acceptable performance. Desirable settings are in the tens to hundreds of megabytes.

Some systems also have a limit on the total amount of shared memory in the system (`SHMALL`). Make sure this is large enough for PostgreSQL plus any other applications that are using shared memory segments. (Caution: `SHMALL` is measured in pages rather than bytes on many systems.)

Less likely to cause problems is the minimum size for shared memory segments (`SHMMIN`), which should be at most approximately 500 kB for PostgreSQL (it is usually just 1). The maximum number of segments system-wide (`SHMMNI`) or per-process (`SHMSEG`) are unlikely to cause a problem unless your system has them set to zero.

PostgreSQL uses one semaphore per allowed connection (`max_connections`) and allowed autovacuum worker process (`autovacuum_max_workers`), in sets of 16. Each such set will also contain a 17th semaphore which contains a “magic number”, to detect collision with semaphore sets used by other applications. The maximum number of semaphores in the system is set by `SEMMNS`, which consequently must be at least as high as `max_connections` plus `autovacuum_max_workers`, plus one extra for each 16 allowed connections plus workers (see the formula in Table 17-1). The parameter `SEMMNI` determines the limit on the number of semaphore sets that can exist on the system at one time. Hence this parameter must be at least `ceil((max_connections + autovacuum_max_workers) / 16)`. Lowering the number of allowed connections is a temporary workaround for failures, which are usually confusingly worded `No space left on device`, from the function `semget`.

In some cases it might also be necessary to increase `SEMMAP` to be at least on the order of `SEMMNS`. This parameter defines the size of the semaphore resource map, in which each contiguous block of available semaphores needs an entry. When a semaphore set is freed it is either added to an existing entry that is adjacent to the freed block or it is registered under a new map entry. If the map is full, the freed semaphores get lost (until reboot). Fragmentation of the semaphore space could over time lead to fewer available semaphores than there should be.

The `SEMMSL` parameter, which determines how many semaphores can be in a set, must be at least 17 for PostgreSQL.

Various other settings related to “semaphore undo”, such as `SEMMNU` and `SEMUME`, are not of concern for PostgreSQL.

## AIX

At least as of version 5.1, it should not be necessary to do any special configuration for such parameters as `SHMMAX`, as it appears this is configured to allow all memory to be used as shared memory. That is the sort of configuration commonly used for other databases such as DB/2.

It might, however, be necessary to modify the global `ulimit` information in `/etc/security/limits`, as the default hard limits for file sizes (`fsize`) and numbers of files (`nofiles`) might be too low.

## BSD/OS

**Shared Memory.** By default, only 4 MB of shared memory is supported. Keep in mind that shared memory is not pageable; it is locked in RAM. To increase the amount of shared memory supported by your system, add something like the following to your kernel configuration file:

```
options "SHMALL=8192"
options "SHMMAX=\(SHMALL*PAGE_SIZE\)"
```

`SHMALL` is measured in 4 kB pages, so a value of 1024 represents 4 MB of shared memory. Therefore the above increases the maximum shared memory area to 32 MB. For those running 4.3 or later, you will probably also need to increase `KERNEL_VIRTUAL_MB` above the default 248. Once all changes have been made, recompile the kernel, and reboot.

For those running 4.0 and earlier releases, use `bpatch` to find the `sysptsize` value in the current kernel. This is computed dynamically at boot time.

```
$ bpatch -r sysptsize
0x9 = 9
```

Next, add `SYSPTSIZE` as a hard-coded value in the kernel configuration file. Increase the value you found using `bpatch`. Add 1 for every additional 4 MB of shared memory you desire.

```
options "SYSPTSIZE=16"
sysptsize cannot be changed by sysctl.
```

**Semaphores.** You will probably want to increase the number of semaphores as well; the default system total of 60 will only allow about 50 PostgreSQL connections. Set the values you want in your kernel configuration file, e.g.:

```
options "SEMMNI=40"
options "SEMMNS=240"
```

## FreeBSD

The default settings are only suitable for small installations (for example, default `SHMMAX` is 32 MB). Changes can be made via the `sysctl` or `loader` interfaces. The following parameters can be set using `sysctl`:

```
$ sysctl -w kern.ipc.shmall=32768
$ sysctl -w kern.ipc.shmmax=134217728
$ sysctl -w kern.ipc.semmap=256
```

To have these settings persist over reboots, modify `/etc/sysctl.conf`.

The remaining semaphore settings are read-only as far as `sysctl` is concerned, but can be changed before boot using the `loader` prompt:

```
(loader) set kern.ipc.semmni=256
(loader) set kern.ipc.semmns=512
(loader) set kern.ipc.semmnu=256
```

Similarly these can be saved between reboots in `/boot/loader.conf`.

You might also want to configure your kernel to lock shared memory into RAM and prevent it from being paged out to swap. This can be accomplished using the `sysctl` setting `kern.ipc.shm_use_phys`.

If running in FreeBSD jails by enabling `sysctl`'s `security.jail.sysvipc_allowed`, postmasters running in different jails should be run by different operating system users. This improves security because it prevents non-root users from interfering with shared memory or semaphores in a different jail, and it allows the PostgreSQL IPC cleanup code to function properly. (In FreeBSD 6.0 and later the IPC cleanup code doesn't properly detect processes in other jails, preventing the running of postmasters on the same port in different jails.)

FreeBSD versions before 4.0 work like NetBSD and OpenBSD (see below).

#### NetBSD

#### OpenBSD

The options `SYSVSHM` and `SYSVSEM` need to be enabled when the kernel is compiled. (They are by default.) The maximum size of shared memory is determined by the option `SHMMAXPGS` (in pages). The following shows an example of how to set the various parameters (OpenBSD uses `option` instead):

```
options      SYSVSHM
options      SHMMAXPGS=4096
options      SHMSEG=256

options      SYSVSEM
options      SEMMNI=256
options      SEMMNS=512
options      SEMMNU=256
options      SEMMAP=256
```

You might also want to configure your kernel to lock shared memory into RAM and prevent it from being paged out to swap. This can be accomplished using the `sysctl` setting `kern.ipc.shm_use_phys`.

#### HP-UX

The default settings tend to suffice for normal installations. On HP-UX 10, the factory default for `SEMMNS` is 128, which might be too low for larger database sites.

IPC parameters can be set in the System Administration Manager (SAM) under Kernel Configuration→Configurable Parameters. Hit Create A New Kernel when you're done.

#### Linux

The default maximum segment size is 32 MB, which is only adequate for small PostgreSQL installations. However, the remaining defaults are quite generously sized, and usually do not require changes. The maximum shared memory segment size can be changed via the `sysctl` interface. For example, to allow 128 MB, and explicitly set the maximum total shared memory size to 2097152 pages (the default):

```
$ sysctl -w kernel.shmmax=134217728
$ sysctl -w kernel.shmall=2097152
```

In addition these settings can be saved between reboots in `/etc/sysctl.conf`.

Older distributions might not have the `sysctl` program, but equivalent changes can be made by manipulating the `/proc` file system:

```
$ echo 134217728 >/proc/sys/kernel/shmmax
$ echo 2097152 >/proc/sys/kernel/shmall
```

## MacOS X

In OS X 10.2 and earlier, edit the file `/System/Library/StartupItems/SystemTuning/SystemTuning` and change the values in the following commands:

```
sysctl -w kern.sysv.shmmax
sysctl -w kern.sysv.shmmin
sysctl -w kern.sysv.shmmni
sysctl -w kern.sysv.shmseg
sysctl -w kern.sysv.shmall
```

In OS X 10.3 and later, these commands have been moved to `/etc/rc` and must be edited there. Note that `/etc/rc` is usually overwritten by OS X updates (such as 10.3.6 to 10.3.7) so you should expect to have to redo your editing after each update.

In OS X 10.3.9 and later, instead of editing `/etc/rc` you can create a file named `/etc/sysctl.conf`, containing variable assignments such as:

```
kern.sysv.shmmax=4194304
kern.sysv.shmmin=1
kern.sysv.shmmni=32
kern.sysv.shmseg=8
kern.sysv.shmall=1024
```

This method is better than editing `/etc/rc` because your changes will be preserved across system updates. Note that *all five* shared-memory parameters must be set in `/etc/sysctl.conf`, else the values will be ignored.

Beware that recent releases of OS X ignore attempts to set `SHMMAX` to a value that isn't an exact multiple of 4096.

`SHMALL` is measured in 4 kB pages on this platform.

In all OS X versions, you'll need to reboot to make changes in the shared memory parameters take effect.

## SCO OpenServer

In the default configuration, only 512 kB of shared memory per segment is allowed. To increase the setting, first change to the directory `/etc/conf/cf.d`. To display the current value of `SHMMAX`, run:

```
./configure -y SHMMAX
```

To set a new value for `SHMMAX`, run:

```
./configure SHMMAX=value
```

where *value* is the new value you want to use (in bytes). After setting `SHMMAX`, rebuild the kernel:

```
./link_unix
```

and reboot.

## Solaris

At least in version 2.6, the default maximum size of a shared memory segment is too low for PostgreSQL. The relevant settings can be changed in `/etc/system`, for example:

```
set shmsys:shminfo_shmmax=0x2000000
set shmsys:shminfo_shmmin=1
set shmsys:shminfo_shmmni=256
set shmsys:shminfo_shmseg=256
```

```
set semsys:seminfo_semmap=256
set semsys:seminfo_semmni=512
set semsys:seminfo_semmns=512
set semsys:seminfo_semmsl=32
```

You need to reboot for the changes to take effect.

See also <http://sunsite.uakom.sk/sunworldonline/swol-09-1997/swol-09-insidesolaris.html> for information on shared memory under Solaris.

#### UnixWare

On UnixWare 7, the maximum size for shared memory segments is only 512 kB in the default configuration. To display the current value of `SHMMAX`, run:

```
/etc/conf/bin/ldtune -g SHMMAX
```

which displays the current, default, minimum, and maximum values. To set a new value for `SHMMAX`, run:

```
/etc/conf/bin/ldtune SHMMAX value
```

where *value* is the new value you want to use (in bytes). After setting `SHMMAX`, rebuild the kernel:

```
/etc/conf/bin/ldbuild -B
```

and reboot.

**Table 17-2. Configuration parameters affecting PostgreSQL’s shared memory usage**

Name	Approximate multiplier (bytes per increment) as of 8.3
<code>max_connections</code>	$1800 + 270 * \text{max\_locks\_per\_transaction}$
<code>autovacuum_max_workers</code>	$1800 + 270 * \text{max\_locks\_per\_transaction}$
<code>max_prepared_transactions</code>	$770 + 270 * \text{max\_locks\_per\_transaction}$
<code>shared_buffers</code>	8400 (assuming 8 kB <code>BLCKSZ</code> )
<code>wal_buffers</code>	8200 (assuming 8 kB <code>XLOG_BLCKSZ</code> )
<code>max_fsm_relations</code>	70
<code>max_fsm_pages</code>	6
Fixed space requirements	770 kB

### 17.4.2. Resource Limits

Unix-like operating systems enforce various kinds of resource limits that might interfere with the operation of your PostgreSQL server. Of particular importance are limits on the number of processes per user, the number of open files per process, and the amount of memory available to each process. Each of these have a “hard” and a “soft” limit. The soft limit is what actually counts but it can be changed by the user up to the hard limit. The hard limit can only be changed by the root user. The system call `setrlimit` is responsible for setting these parameters. The shell’s built-in command `ulimit` (Bourne shells) or `limit` (csh) is used to control the resource limits from the command line. On BSD-derived systems the file `/etc/login.conf` controls the various resource limits set during login. See the operating system documentation for details. The relevant parameters are `maxproc`, `openfiles`, and `datasize`.

For example:

```
default:\
...
      :datasize-cur=256M:\
      :maxproc-cur=256:\
      :openfiles-cur=256:\
...
```

(`-cur` is the soft limit. Append `-max` to set the hard limit.)

Kernels can also have system-wide limits on some resources.

- On Linux `/proc/sys/fs/file-max` determines the maximum number of open files that the kernel will support. It can be changed by writing a different number into the file or by adding an assignment in `/etc/sysctl.conf`. The maximum limit of files per process is fixed at the time the kernel is compiled; see `/usr/src/linux/Documentation/proc.txt` for more information.

The PostgreSQL server uses one process per connection so you should provide for at least as many processes as allowed connections, in addition to what you need for the rest of your system. This is usually not a problem but if you run several servers on one machine things might get tight.

The factory default limit on open files is often set to “socially friendly” values that allow many users to coexist on a machine without using an inappropriate fraction of the system resources. If you run many servers on a machine this is perhaps what you want, but on dedicated servers you might want to raise this limit.

On the other side of the coin, some systems allow individual processes to open large numbers of files; if more than a few processes do so then the system-wide limit can easily be exceeded. If you find this happening, and you do not want to alter the system-wide limit, you can set PostgreSQL’s `max_files_per_process` configuration parameter to limit the consumption of open files.

### 17.4.3. Linux Memory Overcommit

In Linux 2.4 and later, the default virtual memory behavior is not optimal for PostgreSQL. Because of the way that the kernel implements memory overcommit, the kernel might terminate the PostgreSQL server (the master server process) if the memory demands of another process cause the system to run out of virtual memory.

If this happens, you will see a kernel message that looks like this (consult your system documentation and configuration on where to look for such a message):

```
Out of Memory: Killed process 12345 (postgres).
```

This indicates that the `postgres` process has been terminated due to memory pressure. Although existing database connections will continue to function normally, no new connections will be accepted. To recover, PostgreSQL will need to be restarted.

One way to avoid this problem is to run PostgreSQL on a machine where you can be sure that other processes will not run the machine out of memory. If memory is tight, increasing the swap space of the

operating system can help avoiding the problem, because the out-of-memory (OOM) killer is invoked whenever physical memory and swap space are exhausted.

On Linux 2.6 and later, an additional measure is to modify the kernel's behavior so that it will not "over-commit" memory. Although this setting will not prevent the OOM killer<sup>1</sup> from being invoked altogether, it will lower the chances significantly and will therefore lead to more robust system behavior. This is done by selecting strict overcommit mode via `sysctl`:

```
sysctl -w vm.overcommit_memory=2
```

or placing an equivalent entry in `/etc/sysctl.conf`. You might also wish to modify the related setting `vm.overcommit_ratio`. For details see the kernel documentation file `Documentation/vm/overcommit-accounting`.

Some vendors' Linux 2.4 kernels are reported to have early versions of the 2.6 overcommit `sysctl` parameter. However, setting `vm.overcommit_memory` to 2 on a kernel that does not have the relevant code will make things worse not better. It is recommended that you inspect the actual kernel source code (see the function `vm_enough_memory` in the file `mm/mmap.c`) to verify what is supported in your copy before you try this in a 2.4 installation. The presence of the `overcommit-accounting` documentation file should *not* be taken as evidence that the feature is there. If in any doubt, consult a kernel expert or your kernel vendor.

## 17.5. Shutting Down the Server

There are several ways to shut down the database server. You control the type of shutdown by sending different signals to the master `postgres` process.

### SIGTERM

After receiving SIGTERM, the server disallows new connections, but lets existing sessions end their work normally. It shuts down only after all of the sessions terminate normally. This is the *Smart Shutdown*.

### SIGINT

The server disallows new connections and sends all existing server processes SIGTERM, which will cause them to abort their current transactions and exit promptly. It then waits for the server processes to exit and finally shuts down. This is the *Fast Shutdown*.

### SIGQUIT

This is the *Immediate Shutdown*, which will cause the master `postgres` process to send a SIGQUIT to all child processes and exit immediately, without properly shutting itself down. The child processes likewise exit immediately upon receiving SIGQUIT. This will lead to recovery (by replaying the WAL log) upon next start-up. This is recommended only in emergencies.

The `pg_ctl` program provides a convenient interface for sending these signals to shut down the server. Alternatively, you can send the signal directly using `kill` on non-Windows systems. The PID of the

---

1. <http://lwn.net/Articles/104179/>

`postgres` process can be found using the `ps` program, or from the file `postmaster.pid` in the data directory. For example, to do a fast shutdown:

```
$ kill -INT `head -1 /usr/local/pgsql/data/postmaster.pid`
```

**Important:** It is best not to use `SIGKILL` to shut down the server. Doing so will prevent the server from releasing shared memory and semaphores, which might then have to be done manually before a new server can be started. Furthermore, `SIGKILL` kills the `postgres` process without letting it relay the signal to its subprocesses, so it will be necessary to kill the individual subprocesses by hand as well.

## 17.6. Preventing Server Spoofing

While the server is running, it is not possible for a malicious user to interfere with client/server communications. However, when the server is down it is possible for a local user to spoof the normal server by starting their own server. The spoof server could read passwords and queries sent by clients, but could not return any data because the `PGDATA` directory would still be secure because of directory permissions. Spoofing is possible because any user can start a database server; a client cannot identify an invalid server unless it is specially configured.

The simplest way to prevent invalid servers for `local` connections is to use a Unix domain socket directory (`unix_socket_directory`) that has write permission only for a trusted local user. This prevents a malicious user from creating their own socket file in that directory. If you are concerned that some applications might still reference `/tmp` for the socket file and hence be vulnerable to spoofing, during operating system startup create symbolic link `/tmp/.s.PGSQL.5432` that points to the relocated socket file. You also might need to modify your `/tmp` cleanup script to preserve the symbolic link.

For TCP connections the server must accept only `hostssl` connections (Section 21.1) and have `SSL server.key` (key) and `server.crt` (certificate) files (Section 17.8). The TCP client must connect using `sslmode='require'` (Section 30.1) and have a `~/.postgresql/root.crt` SSL certificate (Section 30.16).

## 17.7. Encryption Options

PostgreSQL offers encryption at several levels, and provides flexibility in protecting data from disclosure due to database server theft, unscrupulous administrators, and insecure networks. Encryption might also be required to secure sensitive data such as medical records or financial transactions.

### Password Storage Encryption

By default, database user passwords are stored as MD5 hashes, so the administrator cannot determine the actual password assigned to the user. If MD5 encryption is used for client authentication, the unencrypted password is never even temporarily present on the server because the client MD5 encrypts it before being sent across the network.

### Encryption For Specific Columns

The `contrib` function library `pgcrypto` allows certain fields to be stored encrypted. This is useful if only some of the data is sensitive. The client supplies the decryption key and the data is decrypted on the server and then sent to the client.

The decrypted data and the decryption key are present on the server for a brief time while it is being decrypted and communicated between the client and server. This presents a brief moment where the data and keys can be intercepted by someone with complete access to the database server, such as the system administrator.

### Data Partition Encryption

On Linux, encryption can be layered on top of a file system mount using a “loopback device”. This allows an entire file system partition be encrypted on disk, and decrypted by the operating system. On FreeBSD, the equivalent facility is called GEOM Based Disk Encryption, or `gbde`.

This mechanism prevents unencrypted data from being read from the drives if the drives or the entire computer is stolen. This does not protect against attacks while the file system is mounted, because when mounted, the operating system provides an unencrypted view of the data. However, to mount the file system, you need some way for the encryption key to be passed to the operating system, and sometimes the key is stored somewhere on the host that mounts the disk.

### Encrypting Passwords Across A Network

The MD5 authentication method double-encrypts the password on the client before sending it to the server. It first MD5 encrypts it based on the user name, and then encrypts it based on a random salt sent by the server when the database connection was made. It is this double-encrypted value that is sent over the network to the server. Double-encryption not only prevents the password from being discovered, it also prevents another connection from using the same encrypted password to connect to the database server at a later time.

### Encrypting Data Across A Network

SSL connections encrypt all data sent across the network: the password, the queries, and the data returned. The `pg_hba.conf` file allows administrators to specify which hosts can use non-encrypted connections (`host`) and which require SSL-encrypted connections (`hostssl`). Also, clients can specify that they connect to servers only via SSL. Stunnel or SSH can also be used to encrypt transmissions.

### SSL Host Authentication

It is possible for both the client and server to provide SSL keys or certificates to each other. It takes some extra configuration on each side, but this provides stronger verification of identity than the mere use of passwords. It prevents a computer from pretending to be the server just long enough to read the password sent by the client. It also helps prevent “man in the middle” attacks where a computer between the client and server pretends to be the server and reads and passes all data between the client and server.

### Client-Side Encryption

If the system administrator cannot be trusted, it is necessary for the client to encrypt the data; this way, unencrypted data never appears on the database server. Data is encrypted on the client before being sent to the server, and database results have to be decrypted on the client before being used.

## 17.8. Secure TCP/IP Connections with SSL

PostgreSQL has native support for using SSL connections to encrypt client/server communications for increased security. This requires that OpenSSL is installed on both client and server systems and that support in PostgreSQL is enabled at build time (see Chapter 15).

With SSL support compiled in, the PostgreSQL server can be started with SSL enabled by setting the parameter `ssl` to `on` in `postgresql.conf`. The server will listen for both standard and SSL connections on the same TCP port, and will negotiate with any connecting client on whether to use SSL. By default, this is at the client's option; see Section 21.1 about how to set up the server to require use of SSL for some or all connections.

PostgreSQL reads the system-wide OpenSSL configuration file. By default, this file is named `openssl.cnf` and is located in the directory reported by `openssl version -d`. This default can be overridden by setting environment variable `OPENSSL_CONF` to the name of the desired configuration file.

OpenSSL supports a wide range of ciphers and authentication algorithms, of varying strength. While a list of ciphers can be specified in the OpenSSL configuration file, you can specify ciphers specifically for use by the database server by modifying `ssl_ciphers` in `postgresql.conf`.

**Note:** It is possible to have authentication without encryption overhead by using `NULL-SHA` or `NULL-MD5` ciphers. However, a man-in-the-middle could read and pass communications between client and server. Also, encryption overhead is minimal compared to the overhead of authentication. For these reasons NULL ciphers are not recommended.

To start in SSL mode, the files `server.crt` and `server.key` must exist in the server's data directory. These files should contain the server certificate and private key, respectively. If the private key is protected with a passphrase, the server will prompt for the passphrase and will not start until it has been entered.

To require the client to supply a trusted certificate, place certificates of the certificate authorities (CA) you trust in the file `root.crt` in the data directory. A certificate will then be requested from the client during SSL connection startup. (See Section 30.16 for a description of how to set up client certificates.) The server will verify that the client's certificate is signed by one of the trusted certificate authorities. Certificate Revocation List (CRL) entries are also checked if the file `root.crl` exists. (See [http://h71000.www7.hp.com/DOC/83final/BA554\\_90007/ch04s02.html](http://h71000.www7.hp.com/DOC/83final/BA554_90007/ch04s02.html) for diagrams showing SSL certificate usage.)

If the `root.crt` file is not present, client certificates will not be requested or checked. In this mode, SSL provides encrypted communication but not authentication.

The files `server.key`, `server.crt`, `root.crt`, and `root.crl` are only examined during server start; so you must restart the server for changes in them to take effect.

**Table 17-3. SSL Server File Usage**

File	Contents	Effect
<code>server.crt</code>	server certificate	requested by client
<code>server.key</code>	server private key	proves server certificate sent by owner; does not indicate certificate owner is trustworthy

File	Contents	Effect
root.crt	trusted certificate authorities	requests client certificate; checks certificate is signed by a trusted certificate authority
root.crl	certificates revoked by certificate authorities	client certificate must not be on this list

### 17.8.1. Creating a Self-Signed Certificate

To create a quick self-signed certificate for the server, use the following OpenSSL command:

```
openssl req -new -text -out server.req
```

Fill out the information that openssl asks for. Make sure you enter the local host name as “Common Name”; the challenge password can be left blank. The program will generate a key that is passphrase protected; it will not accept a passphrase that is less than four characters long. To remove the passphrase (as you must if you want automatic start-up of the server), run the commands:

```
openssl rsa -in privkey.pem -out server.key
rm privkey.pem
```

Enter the old passphrase to unlock the existing key. Now do:

```
openssl req -x509 -in server.req -text -key server.key -out server.crt
chmod og-rwx server.key
```

to turn the certificate into a self-signed certificate and to copy the key and certificate to where the server will look for them. For more details on how to create your server private key and certificate, refer to the OpenSSL documentation.

A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) (either one of the global CAs or a local one) should be used in production so the client can verify the server’s identity.

## 17.9. Secure TCP/IP Connections with SSH Tunnels

One can use SSH to encrypt the network connection between clients and a PostgreSQL server. Done properly, this provides an adequately secure network connection, even for non-SSL-capable clients.

First make sure that an SSH server is running properly on the same machine as the PostgreSQL server and that you can log in using `ssh` as some user. Then you can establish a secure tunnel with a command like this from the client machine:

```
ssh -L 3333:foo.com:5432 joe@foo.com
```

The first number in the `-L` argument, 3333, is the port number of your end of the tunnel; it can be chosen freely. The second number, 5432, is the remote end of the tunnel: the port number your server is using. The name or IP address between the port numbers is the host with the database server you are going to

connect to. In order to connect to the database server using this tunnel, you connect to port 3333 on the local machine:

```
psql -h localhost -p 3333 postgres
```

To the database server it will then look as though you are really user `joe@foo.com` and it will use whatever authentication procedure was configured for connections from this user and host. Note that the server will not think the connection is SSL-encrypted, since in fact it is not encrypted between the SSH server and the PostgreSQL server. This should not pose any extra security risk as long as they are on the same machine.

In order for the tunnel setup to succeed you must be allowed to connect via `ssh` as `joe@foo.com`, just as if you had attempted to use `ssh` to set up a terminal session.

**Tip:** Several other applications exist that can provide secure tunnels using a procedure similar in concept to the one just described.

# Chapter 18. Server Configuration

There are many configuration parameters that affect the behavior of the database system. In the first section of this chapter, we describe how to set configuration parameters. The subsequent sections discuss each parameter in detail.

## 18.1. Setting Parameters

All parameter names are case-insensitive. Every parameter takes a value of one of four types: Boolean, integer, floating point, or string. Boolean values can be written as ON, OFF, TRUE, FALSE, YES, NO, 1, 0 (all case-insensitive) or any unambiguous prefix of these.

Some settings specify a memory or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Default units can be queried by referencing `pg_settings.unit`. For convenience, a different unit can also be specified explicitly. Valid memory units are kB (kilobytes), MB (megabytes), and GB (gigabytes); valid time units are ms (milliseconds), s (seconds), min (minutes), h (hours), and d (days). Note that the multiplier for memory units is 1024, not 1000.

One way to set these parameters is to edit the file `postgresql.conf`, which is normally kept in the data directory. (`initdb` installs a default copy there.) An example of what this file might look like is:

```
# This is a comment
log_connections = yes
log_destination = 'syslog'
search_path = '$user', public
shared_buffers = 128MB
```

One parameter is specified per line. The equal sign between name and value is optional. Whitespace is insignificant and blank lines are ignored. Hash marks (`#`) introduce comments anywhere. Parameter values that are not simple identifiers or numbers must be single-quoted. To embed a single quote in a parameter value, write either two quotes (preferred) or backslash-quote.

In addition to parameter settings, the `postgresql.conf` file can contain *include directives*, which specify another file to read and process as if it were inserted into the configuration file at this point. Include directives simply look like:

```
include 'filename'
```

If the file name is not an absolute path, it is taken as relative to the directory containing the referencing configuration file. Inclusions can be nested.

The configuration file is reread whenever the main server process receives a SIGHUP signal (which is most easily sent by means of `pg_ctl reload`). The main server process also propagates this signal to all currently running server processes so that existing sessions also get the new value. Alternatively, you can send the signal to a single server process directly. Some parameters can only be set at server start; any changes to their entries in the configuration file will be ignored until the server is restarted.

A second way to set these configuration parameters is to give them as a command-line option to the `postgres` command, such as:

```
postgres -c log_connections=yes -c log_destination='syslog'
```

Command-line options override any conflicting settings in `postgresql.conf`. Note that this means you won't be able to change the value on-the-fly by editing `postgresql.conf`, so while the command-line method might be convenient, it can cost you flexibility later.

Occasionally it is useful to give a command line option to one particular session only. The environment variable `PGOPTIONS` can be used for this purpose on the client side:

```
env PGOPTIONS='-c geqo=off' psql
```

(This works for any libpq-based client application, not just `psql`.) Note that this won't work for parameters that are fixed when the server is started or that must be specified in `postgresql.conf`.

Furthermore, it is possible to assign a set of parameter settings to a user or a database. Whenever a session is started, the default settings for the user and database involved are loaded. The commands *ALTER USER* and *ALTER DATABASE*, respectively, are used to configure these settings. Per-database settings override anything received from the `postgres` command-line or the configuration file, and in turn are overridden by per-user settings; both are overridden by per-session settings.

Some parameters can be changed in individual SQL sessions with the *SET* command, for example:

```
SET ENABLE_SEQSCAN TO OFF;
```

If *SET* is allowed, it overrides all other sources of values for the parameter. Some parameters cannot be changed via *SET*: for example, if they control behavior that cannot be changed without restarting the entire PostgreSQL server. Also, some parameters can be modified via *SET* or *ALTER* by superusers, but not by ordinary users.

The *SHOW* command allows inspection of the current values of all parameters.

The virtual table `pg_settings` (described in Section 44.51) also allows displaying and updating session run-time parameters. It is equivalent to *SHOW* and *SET*, but can be more convenient to use because it can be joined with other tables, or selected from using any desired selection condition.

## 18.2. File Locations

In addition to the `postgresql.conf` file already mentioned, PostgreSQL uses two other manually-edited configuration files, which control client authentication (their use is discussed in Chapter 21). By default, all three configuration files are stored in the database cluster's data directory. The parameters described in this section allow the configuration files to be placed elsewhere. (Doing so can ease administration. In particular it is often easier to ensure that the configuration files are properly backed-up when they are kept separate.)

`data_directory (string)`

Specifies the directory to use for data storage. This parameter can only be set at server start.

`config_file (string)`

Specifies the main server configuration file (customarily called `postgresql.conf`). This parameter can only be set on the `postgres` command line.

`hba_file (string)`

Specifies the configuration file for host-based authentication (customarily called `pg_hba.conf`). This parameter can only be set at server start.

`ident_file (string)`

Specifies the configuration file for ident authentication (customarily called `pg_ident.conf`). This parameter can only be set at server start.

`external_pid_file (string)`

Specifies the name of an additional process-id (PID) file that the server should create for use by server administration programs. This parameter can only be set at server start.

In a default installation, none of the above parameters are set explicitly. Instead, the data directory is specified by the `-D` command-line option or the `PGDATA` environment variable, and the configuration files are all found within the data directory.

If you wish to keep the configuration files elsewhere than the data directory, the `postgres -D` command-line option or `PGDATA` environment variable must point to the directory containing the configuration files, and the `data_directory` parameter must be set in `postgresql.conf` (or on the command line) to show where the data directory is actually located. Notice that `data_directory` overrides `-D` and `PGDATA` for the location of the data directory, but not for the location of the configuration files.

If you wish, you can specify the configuration file names and locations individually using the parameters `config_file`, `hba_file` and/or `ident_file`. `config_file` can only be specified on the `postgres` command line, but the others can be set within the main configuration file. If all three parameters plus `data_directory` are explicitly set, then it is not necessary to specify `-D` or `PGDATA`.

When setting any of these parameters, a relative path will be interpreted with respect to the directory in which `postgres` is started.

## 18.3. Connections and Authentication

### 18.3.1. Connection Settings

`listen_addresses (string)`

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications. The value takes the form of a comma-separated list of host names and/or numeric IP addresses. The special entry `*` corresponds to all available IP interfaces. If the list is empty, the server does not listen on any IP interface at all, in which case only Unix-domain sockets can be used to connect to it. The default value is `localhost`, which allows only local “loopback” connections to be made. This parameter can only be set at server start.

`port (integer)`

The TCP port the server listens on; 5432 by default. Note that the same port number is used for all IP addresses the server listens on. This parameter can only be set at server start.

`max_connections (integer)`

Determines the maximum number of concurrent connections to the database server. The default is typically 100 connections, but might be less if your kernel settings will not support it (as determined during `initdb`). This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory or semaphores than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

`superuser_reserved_connections (integer)`

Determines the number of connection “slots” that are reserved for connections by PostgreSQL superusers. At most `max_connections` connections can ever be active simultaneously. Whenever the number of active concurrent connections is at least `max_connections` minus `superuser_reserved_connections`, new connections will be accepted only for superusers.

The default value is three connections. The value must be less than the value of `max_connections`. This parameter can only be set at server start.

`unix_socket_directory (string)`

Specifies the directory of the Unix-domain socket on which the server is to listen for connections from client applications. The default is normally `/tmp`, but can be changed at build time. This parameter can only be set at server start.

`unix_socket_group (string)`

Sets the owning group of the Unix-domain socket. (The owning user of the socket is always the user that starts the server.) In combination with the parameter `unix_socket_permissions` this can be used as an additional access control mechanism for Unix-domain connections. By default this is the empty string, which selects the default group for the current user. This parameter can only be set at server start.

`unix_socket_permissions (integer)`

Sets the access permissions of the Unix-domain socket. Unix-domain sockets use the usual Unix file system permission set. The parameter value is expected to be a numeric mode specification in the form accepted by the `chmod` and `umask` system calls. (To use the customary octal format the number must start with a 0 (zero).)

The default permissions are `0777`, meaning anyone can connect. Reasonable alternatives are `0770` (only user and group, see also `unix_socket_group`) and `0700` (only user). (Note that for a Unix-domain socket, only write permission matters and so there is no point in setting or revoking read or execute permissions.)

This access control mechanism is independent of the one described in Chapter 21.

This parameter can only be set at server start.

`bonjour_name (string)`

Specifies the Bonjour broadcast name. The computer name is used if this parameter is set to the empty string “” (which is the default). This parameter is ignored if the server was not compiled with Bonjour support. This parameter can only be set at server start.

`tcp_keepalives_idle (integer)`

On systems that support the `TCP_KEEPIDL` socket option, specifies the number of seconds between sending keepalives on an otherwise idle connection. A value of zero uses the system default. If `TCP_KEEPIDL` is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

`tcp_keepalives_interval (integer)`

On systems that support the `TCP_KEEPINTVL` socket option, specifies how long, in seconds, to wait for a response to a keepalive before retransmitting. A value of zero uses the system default. If `TCP_KEEPINTVL` is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

`tcp_keepalives_count (integer)`

On systems that support the `TCP_KEEPCNT` socket option, specifies how many keepalives can be lost before the connection is considered dead. A value of zero uses the system default. If `TCP_KEEPCNT` is not supported, this parameter must be zero. This parameter is ignored for connections made via a Unix-domain socket.

## 18.3.2. Security and Authentication

`authentication_timeout (integer)`

Maximum time to complete client authentication, in seconds. If a would-be client has not completed the authentication protocol in this much time, the server breaks the connection. This prevents hung clients from occupying a connection indefinitely. The default is one minute (1m). This parameter can only be set in the `postgresql.conf` file or on the server command line.

`ssl (boolean)`

Enables SSL connections. Please read Section 17.8 before using this. The default is `off`. This parameter can only be set at server start.

`ssl_ciphers (string)`

Specifies a list of SSL ciphers that are allowed to be used on secure connections. See the openssl manual page for a list of supported ciphers.

`password_encryption (boolean)`

When a password is specified in `CREATE USER` or `ALTER USER` without writing either `ENCRYPTED` or `UNENCRYPTED`, this parameter determines whether the password is to be encrypted. The default is `on` (encrypt the password).

`krb_realm (string)`

Sets the realm to match Kerberos, GSSAPI and SSPI user names against. See Section 21.2.5, Section 21.2.3 or Section 21.2.4 for details. This parameter can only be set at server start.

`krb_server_keyfile (string)`

Sets the location of the Kerberos server key file. See Section 21.2.5 or Section 21.2.3 for details. This parameter can only be set at server start.

`krb_srvname (string)`

Sets the Kerberos service name. See Section 21.2.5 for details. This parameter can only be set at server start.

`krb_server_hostname (string)`

Sets the host name part of the service principal. This, combined with `krb_srvname`, is used to generate the complete service principal, that is `krb_srvname/krb_server_hostname@REALM`. If not set, the default is the server host name. See Section 21.2.5 for details. This parameter can only be set at server start.

`krb_caseins_users (boolean)`

Sets whether Kerberos and GSSAPI user names should be treated case-insensitively. The default is `off` (case sensitive). This parameter can only be set at server start.

`db_user_namespace (boolean)`

This parameter enables per-database user names. It is off by default. This parameter can only be set in the `postgresql.conf` file or on the server command line.

If this is on, you should create users as `username@dbname`. When `username` is passed by a connecting client, `@` and the database name are appended to the user name and that database-specific user name is looked up by the server. Note that when you create users with names containing `@` within the SQL environment, you will need to quote the user name.

With this parameter enabled, you can still create ordinary global users. Simply append `@` when specifying the user name in the client. The `@` will be stripped off before the user name is looked up by the server.

**Note:** This feature is intended as a temporary measure until a complete solution is found. At that time, this option will be removed.

## 18.4. Resource Consumption

### 18.4.1. Memory

`shared_buffers (integer)`

Sets the amount of memory the database server uses for shared memory buffers. The default is typically 32 megabytes (32MB), but might be less if your kernel settings will not support it (as determined during `initdb`). This setting must be at least 128 kilobytes and at least 16 kilobytes times `max_connections`. (Non-default values of `BLCKSZ` change the minimum.) However, settings significantly higher than the minimum are usually needed for good performance. Several tens of megabytes are recommended for production installations. This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

`temp_buffers (integer)`

Sets the maximum number of temporary buffers used by each database session. These are session-local buffers used only for access to temporary tables. The default is eight megabytes (8MB). The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session; subsequent attempts to change the value will have no effect on that session.

A session will allocate temporary buffers as needed up to the limit given by `temp_buffers`. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor, or about 64 bytes, per increment in `temp_buffers`. However if a buffer is actually used an additional 8192 bytes will be consumed for it (or in general, `BLCKSZ` bytes).

`max_prepared_transactions (integer)`

Sets the maximum number of transactions that can be in the “prepared” state simultaneously (see *PREPARE TRANSACTION*). Setting this parameter to zero disables the prepared-transaction feature. The default is five transactions. This parameter can only be set at server start.

If you are not using prepared transactions, this parameter may as well be set to zero. If you are using them, you will probably want `max_prepared_transactions` to be at least as large as `max_connections`, to avoid unwanted failures at the prepare step.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

`work_mem (integer)`

Specifies the amount of memory to be used by internal sort operations and hash tables before switching to temporary disk files. The value defaults to one megabyte (1MB). Note that for a complex query, several sort or hash operations might be running in parallel; each one will be allowed to use as much memory as this value specifies before it starts to put data into temporary files. Also, several running sessions could be doing such operations concurrently. So the total memory used could be many times the value of `work_mem`; it is necessary to keep this fact in mind when choosing the value. Sort operations are used for `ORDER BY`, `DISTINCT`, and merge joins. Hash tables are used in hash joins, hash-based aggregation, and hash-based processing of `IN` subqueries.

`maintenance_work_mem (integer)`

Specifies the maximum amount of memory to be used in maintenance operations, such as `VACUUM`, `CREATE INDEX`, and `ALTER TABLE ADD FOREIGN KEY`. It defaults to 16 megabytes (16MB). Since only one of these operations can be executed at a time by a database session, and an installation normally doesn't have many of them running concurrently, it's safe to set this value significantly larger than `work_mem`. Larger settings might improve performance for vacuuming and for restoring database dumps.

`max_stack_depth (integer)`

Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by `ulimit -s` or local equivalent), less a safety margin of a megabyte or so. The safety margin is needed because the stack depth is not checked in every routine in the server, but only in key potentially-recursive routines such as

expression evaluation. The default setting is two megabytes (2MB), which is conservatively small and unlikely to risk crashes. However, it might be too small to allow execution of complex functions. Only superusers can change this setting.

Setting `max_stack_depth` higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process. On platforms where PostgreSQL can determine the kernel limit, it will not let you set this variable to an unsafe value. However, not all platforms provide the information, so caution is recommended in selecting a value.

## 18.4.2. Free Space Map

These parameters control the size of the shared *free space map* (FSM), which tracks the locations of unused space in the database. An undersized free space map can cause the database to consume increasing amounts of disk space over time, because free space that is not in the map cannot be re-used; instead PostgreSQL will request more disk space from the operating system when it needs to store new data. The last few lines displayed by a database-wide `VACUUM VERBOSE` command can help in determining if the current settings are adequate. A `NOTICE` message is also printed during such an operation if the current settings are too low.

Increasing these parameters might cause PostgreSQL to request more System V shared memory than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

`max_fsm_pages (integer)`

Sets the maximum number of disk pages for which free space will be tracked in the shared free-space map. Six bytes of shared memory are consumed for each page slot. This setting must be at least 16 \* `max_fsm_relations`. The default is chosen by `initdb` depending on the amount of available memory, and can range from 20k to 200k pages. This parameter can only be set at server start.

`max_fsm_relations (integer)`

Sets the maximum number of relations (tables and indexes) for which free space will be tracked in the shared free-space map. Roughly seventy bytes of shared memory are consumed for each slot. The default is one thousand relations. This parameter can only be set at server start.

**Note:** See the `VACUUM` command for information on setting this parameter.

## 18.4.3. Kernel Resource Usage

`max_files_per_process (integer)`

Sets the maximum number of simultaneously open files allowed to each server subprocess. The default is one thousand files. If the kernel is enforcing a safe per-process limit, you don't need to worry about this setting. But on some platforms (notably, most BSD systems), the kernel will allow individual processes to open many more files than the system can really support when a large number

of processes all try to open that many files. If you find yourself seeing “Too many open files” failures, try reducing this setting. This parameter can only be set at server start.

`shared_preload_libraries (string)`

This variable specifies one or more shared libraries that are to be preloaded at server start. If more than one library is to be loaded, separate their names with commas. For example, `'$libdir/mylib'` would cause `mylib.so` (or on some platforms, `mylib.sl`) to be preloaded from the installation's standard library directory. This parameter can only be set at server start.

PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax `'$libdir/plXXX'` where XXX is `pgsql`, `perl`, `tcl`, or `python`.

By preloading a shared library, the library startup time is avoided when the library is first used. However, the time to start each new server process might increase slightly, even if that process never uses the library. So this parameter is recommended only for libraries that will be used in most sessions.

**Note:** On Windows hosts, preloading a library at server start will not reduce the time required to start each new server process; each server process will re-load all preload libraries. However, `shared_preload_libraries` is still useful on Windows hosts because some shared libraries may need to perform certain operations that only take place at postmaster start (for example, a shared library may need to reserve lightweight locks or shared memory and you can't do that after the postmaster has started).

If a specified library is not found, the server will fail to start.

Every PostgreSQL-supported library has a “magic block” that is checked to guarantee compatibility. For this reason, non-PostgreSQL libraries cannot be loaded in this way.

#### 18.4.4. Cost-Based Vacuum Delay

During the execution of `VACUUM` and `ANALYZE` commands, the system maintains an internal counter that keeps track of the estimated cost of the various I/O operations that are performed. When the accumulated cost reaches a limit (specified by `vacuum_cost_limit`), the process performing the operation will sleep for a while (specified by `vacuum_cost_delay`). Then it will reset the counter and continue execution.

The intent of this feature is to allow administrators to reduce the I/O impact of these commands on concurrent database activity. There are many situations in which it is not very important that maintenance commands like `VACUUM` and `ANALYZE` finish quickly; however, it is usually very important that these commands do not significantly interfere with the ability of the system to perform other database operations. Cost-based vacuum delay provides a way for administrators to achieve this.

This feature is disabled by default. To enable it, set the `vacuum_cost_delay` variable to a nonzero value.

`vacuum_cost_delay (integer)`

The length of time, in milliseconds, that the process will sleep when the cost limit has been exceeded. The default value is zero, which disables the cost-based vacuum delay feature. Positive values enable cost-based vacuuming. Note that on many systems, the effective resolution of sleep delays is 10

milliseconds; setting `vacuum_cost_delay` to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10.

`vacuum_cost_page_hit (integer)`

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page. The default value is one.

`vacuum_cost_page_miss (integer)`

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content. The default value is 10.

`vacuum_cost_page_dirty (integer)`

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again. The default value is 20.

`vacuum_cost_limit (integer)`

The accumulated cost that will cause the vacuuming process to sleep. The default value is 200.

**Note:** There are certain operations that hold critical locks and should therefore complete as quickly as possible. Cost-based vacuum delays do not occur during such operations. Therefore it is possible that the cost accumulates far higher than the specified limit. To avoid uselessly long delays in such cases, the actual delay is calculated as  $\text{vacuum\_cost\_delay} * \text{accumulated\_balance} / \text{vacuum\_cost\_limit}$  with a maximum of  $\text{vacuum\_cost\_delay} * 4$ .

### 18.4.5. Background Writer

There is a separate server process called the *background writer*, whose function is to issue writes of “dirty” shared buffers. The intent is that server processes handling user queries should seldom or never have to wait for a write to occur, because the background writer will do it. However there is a net overall increase in I/O load, because a repeatedly-dirtied page might otherwise be written only once per checkpoint interval, but the background writer might write it several times in the same interval. The parameters discussed in this subsection can be used to tune the behavior for local needs.

`bgwriter_delay (integer)`

Specifies the delay between activity rounds for the background writer. In each round the writer issues writes for some number of dirty buffers (controllable by the following parameters). It then sleeps for `bgwriter_delay` milliseconds, and repeats. The default value is 200 milliseconds (200ms). Note that on many systems, the effective resolution of sleep delays is 10 milliseconds; setting `bgwriter_delay` to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`bgwriter_lru_maxpages` (integer)

In each round, no more than this many buffers will be written by the background writer. Setting this to zero disables background writing (except for checkpoint activity). The default value is 100 buffers. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`bgwriter_lru_multiplier` (floating point)

The number of dirty buffers written in each round is based on the number of new buffers that have been needed by server processes during recent rounds. The average recent need is multiplied by `bgwriter_lru_multiplier` to arrive at an estimate of the number of buffers that will be needed during the next round. Dirty buffers are written until there are that many clean, reusable buffers available. (However, no more than `bgwriter_lru_maxpages` buffers will be written per round.) Thus, a setting of 1.0 represents a “just in time” policy of writing exactly the number of buffers predicted to be needed. Larger values provide some cushion against spikes in demand, while smaller values intentionally leave writes to be done by server processes. The default is 2.0. This parameter can only be set in the `postgresql.conf` file or on the server command line.

Smaller values of `bgwriter_lru_maxpages` and `bgwriter_lru_multiplier` reduce the extra I/O load caused by the background writer, but make it more likely that server processes will have to issue writes for themselves, delaying interactive queries.

## 18.5. Write Ahead Log

See also Section 28.4 for details on WAL and checkpoint tuning.

### 18.5.1. Settings

`fsync` (boolean)

If this parameter is on, the PostgreSQL server will try to make sure that updates are physically written to disk, by issuing `fsync()` system calls or various equivalent methods (see `wal_sync_method`). This ensures that the database cluster can recover to a consistent state after an operating system or hardware crash.

However, using `fsync` results in a performance penalty: when a transaction is committed, PostgreSQL must wait for the operating system to flush the write-ahead log to disk. When `fsync` is disabled, the operating system is allowed to do its best in buffering, ordering, and delaying writes. This can result in significantly improved performance. However, if the system crashes, the results of the last few committed transactions might be lost in part or whole. In the worst case, unrecoverable data corruption might occur. (Crashes of the database software itself are *not* a risk factor here. Only an operating-system-level crash creates a risk of corruption.)

Due to the risks involved, there is no universally correct setting for `fsync`. Some administrators always disable `fsync`, while others only turn it off during initial bulk data loads, where there is a clear restart point if something goes wrong. Others always leave `fsync` enabled. The default is to enable `fsync`, for maximum reliability. If you trust your operating system, your hardware, and your utility company (or your battery backup), you can consider disabling `fsync`.

In many situations, turning off `synchronous_commit` for noncritical transactions can provide much of the potential performance benefit of turning off `fsync`, without the attendant risks of data corruption.

This parameter can only be set in the `postgresql.conf` file or on the server command line. If you turn this parameter off, also consider turning off `full_page_writes`.

`synchronous_commit` (boolean)

Specifies whether transaction commit will wait for WAL records to be written to disk before the command returns a “success” indication to the client. The default, and safe, setting is `on`. When `off`, there can be a delay between when success is reported to the client and when the transaction is really guaranteed to be safe against a server crash. (The maximum delay is three times `wal_writer_delay`.) Unlike `fsync`, setting this parameter to `off` does not create any risk of database inconsistency: a crash might result in some recent allegedly-committed transactions being lost, but the database state will be just the same as if those transactions had been aborted cleanly. So, turning `synchronous_commit` off can be a useful alternative when performance is more important than exact certainty about the durability of a transaction. For more discussion see Section 28.3.

This parameter can be changed at any time; the behavior for any one transaction is determined by the setting in effect when it commits. It is therefore possible, and useful, to have some transactions commit synchronously and others asynchronously. For example, to make a single multi-statement transaction commit asynchronously when the default is the opposite, issue `SET LOCAL synchronous_commit TO OFF` within the transaction.

`wal_sync_method` (string)

Method used for forcing WAL updates out to disk. If `fsync` is off then this setting is irrelevant, since updates will not be forced out at all. Possible values are:

- `open_datasync` (write WAL files with `open()` option `O_DSYNC`)
- `fdasync` (call `fdasync()` at each commit)
- `fsync_writethrough` (call `fsync()` at each commit, forcing write-through of any disk write cache)
- `fsync` (call `fsync()` at each commit)
- `open_sync` (write WAL files with `open()` option `O_SYNC`)

Not all of these choices are available on all platforms. The default is the first method in the above list that is supported by the platform. The `open_*` options also use `O_DIRECT` if available. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`full_page_writes` (boolean)

When this parameter is on, the PostgreSQL server writes the entire content of each disk page to WAL during the first modification of that page after a checkpoint. This is needed because a page write that is in process during an operating system crash might be only partially completed, leading to an on-disk page that contains a mix of old and new data. The row-level change data normally stored in WAL will not be enough to completely restore such a page during post-crash recovery. Storing the full page image guarantees that the page can be correctly restored, but at a price in increasing the amount of data that must be written to WAL. (Because WAL replay always starts from a checkpoint, it is sufficient to do this during the first change of each page after a checkpoint. Therefore, one way to reduce the cost of full-page writes is to increase the checkpoint interval parameters.)

Turning this parameter off speeds normal operation, but might lead to a corrupt database after an operating system crash or power failure. The risks are similar to turning off `fsync`, though smaller. It might be safe to turn off this parameter if you have hardware (such as a battery-backed disk controller) or file-system software that reduces the risk of partial page writes to an acceptably low level (e.g., ReiserFS 4).

Turning off this parameter does not affect use of WAL archiving for point-in-time recovery (PITR) (see Section 24.3).

This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is `on`.

`wal_buffers (integer)`

The amount of memory used in shared memory for WAL data. The default is 64 kilobytes (64kB). The setting need only be large enough to hold the amount of WAL data generated by one typical transaction, since the data is written out to disk at every transaction commit. This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

`wal_writer_delay (integer)`

Specifies the delay between activity rounds for the WAL writer. In each round the writer will flush WAL to disk. It then sleeps for `wal_writer_delay` milliseconds, and repeats. The default value is 200 milliseconds (200ms). Note that on many systems, the effective resolution of sleep delays is 10 milliseconds; setting `wal_writer_delay` to a value that is not a multiple of 10 might have the same results as setting it to the next higher multiple of 10. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`commit_delay (integer)`

Time delay between writing a commit record to the WAL buffer and flushing the buffer out to disk, in microseconds. A nonzero delay can allow multiple transactions to be committed with only one `fsync()` system call, if system load is high enough that additional transactions become ready to commit within the given interval. But the delay is just wasted if no other transactions become ready to commit. Therefore, the delay is only performed if at least `commit_siblings` other transactions are active at the instant that a server process has written its commit record. The default is zero (no delay).

`commit_siblings (integer)`

Minimum number of concurrent open transactions to require before performing the `commit_delay` delay. A larger value makes it more probable that at least one other transaction will become ready to commit during the delay interval. The default is five transactions.

## 18.5.2. Checkpoints

`checkpoint_segments (integer)`

Maximum number of log file segments between automatic WAL checkpoints (each segment is normally 16 megabytes). The default is three segments. Increasing this parameter can increase the

amount of time needed for crash recovery. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`checkpoint_timeout (integer)`

Maximum time between automatic WAL checkpoints, in seconds. The default is five minutes (5min). Increasing this parameter can increase the amount of time needed for crash recovery. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`checkpoint_completion_target (floating point)`

Specifies the target length of checkpoints, as a fraction of the checkpoint interval. The default is 0.5. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`checkpoint_warning (integer)`

Write a message to the server log if checkpoints caused by the filling of checkpoint segment files happen closer together than this many seconds (which suggests that `checkpoint_segments` ought to be raised). The default is 30 seconds (30s). Zero disables the warning. This parameter can only be set in the `postgresql.conf` file or on the server command line.

### 18.5.3. Archiving

`archive_mode (boolean)`

When `archive_mode` is enabled, completed WAL segments can be sent to archive storage by setting `archive_command`. `archive_mode` and `archive_command` are separate variables so that `archive_command` can be changed without leaving archiving mode. This parameter can only be set at server start.

`archive_command (string)`

The shell command to execute to archive a completed segment of the WAL file series. Any `%p` in the string is replaced by the path name of the file to archive, and any `%f` is replaced by the file name only. (The path name is relative to the working directory of the server, i.e., the cluster's data directory.) Use `%%` to embed an actual `%` character in the command. For more information see Section 24.3.1. This parameter can only be set in the `postgresql.conf` file or on the server command line. It is ignored unless `archive_mode` was enabled at server start. If `archive_command` is an empty string (the default) while `archive_mode` is enabled, then WAL archiving is temporarily disabled, but the server continues to accumulate WAL segment files in the expectation that a command will soon be provided.

It is important for the command to return a zero exit status if and only if it succeeds. Examples:

```
archive_command = 'cp "%p" /mnt/server/archivedir/%f'
archive_command = 'copy "%p" /mnt/server/archivedir/%f' # Windows
```

`archive_timeout (integer)`

The `archive_command` is only invoked on completed WAL segments. Hence, if your server generates little WAL traffic (or has slack periods where it does so), there could be a long delay between the completion of a transaction and its safe recording in archive storage. To put a limit on how old unarchived data can be, you can set `archive_timeout` to force the server to switch to a new WAL segment file periodically. When this parameter is greater than zero, the server will switch to a new

segment file whenever this many seconds have elapsed since the last segment file switch. Note that archived files that are closed early due to a forced switch are still the same length as completely full files. Therefore, it is unwise to use a very short `archive_timeout` — it will bloat your archive storage. `archive_timeout` settings of a minute or so are usually reasonable. This parameter can only be set in the `postgresql.conf` file or on the server command line.

## 18.6. Query Planning

### 18.6.1. Planner Method Configuration

These configuration parameters provide a crude method of influencing the query plans chosen by the query optimizer. If the default plan chosen by the optimizer for a particular query is not optimal, a temporary solution can be found by using one of these configuration parameters to force the optimizer to choose a different plan. Turning one of these settings off permanently is seldom a good idea, however. Better ways to improve the quality of the plans chosen by the optimizer include adjusting the *Planner Cost Constants*, running `ANALYZE` more frequently, increasing the value of the `default_statistics_target` configuration parameter, and increasing the amount of statistics collected for specific columns using `ALTER TABLE SET STATISTICS`.

`enable_bitmapscan` (boolean)

Enables or disables the query planner's use of bitmap-scan plan types. The default is `on`.

`enable_hashagg` (boolean)

Enables or disables the query planner's use of hashed aggregation plan types. The default is `on`.

`enable_hashjoin` (boolean)

Enables or disables the query planner's use of hash-join plan types. The default is `on`.

`enable_indexscan` (boolean)

Enables or disables the query planner's use of index-scan plan types. The default is `on`.

`enable_mergejoin` (boolean)

Enables or disables the query planner's use of merge-join plan types. The default is `on`.

`enable_nestloop` (boolean)

Enables or disables the query planner's use of nested-loop join plans. It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is `on`.

`enable_seqscan` (boolean)

Enables or disables the query planner's use of sequential scan plan types. It's not possible to suppress sequential scans entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is `on`.

`enable_sort (boolean)`

Enables or disables the query planner's use of explicit sort steps. It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the planner from using one if there are other methods available. The default is `on`.

`enable_tidscan (boolean)`

Enables or disables the query planner's use of TID scan plan types. The default is `on`.

## 18.6.2. Planner Cost Constants

The *cost* variables described in this section are measured on an arbitrary scale. Only their relative values matter, hence scaling them all up or down by the same factor will result in no change in the planner's choices. Traditionally, these variables have been referenced to sequential page fetches as the unit of cost; that is, `seq_page_cost` is conventionally set to 1.0 and the other cost variables are set with reference to that. But you can use a different scale if you prefer, such as actual execution times in milliseconds on a particular machine.

**Note:** Unfortunately, there is no well-defined method for determining ideal values for the cost variables. They are best treated as averages over the entire mix of queries that a particular installation will get. This means that changing them on the basis of just a few experiments is very risky.

`seq_page_cost (floating point)`

Sets the planner's estimate of the cost of a disk page fetch that is part of a series of sequential fetches. The default is 1.0.

`random_page_cost (floating point)`

Sets the planner's estimate of the cost of a non-sequentially-fetched disk page. The default is 4.0. Reducing this value relative to `seq_page_cost` will cause the system to prefer index scans; raising it will make index scans look relatively more expensive. You can raise or lower both values together to change the importance of disk I/O costs relative to CPU costs, which are described by the following parameters.

**Tip:** Although the system will let you set `random_page_cost` to less than `seq_page_cost`, it is not physically sensible to do so. However, setting them equal makes sense if the database is entirely cached in RAM, since in that case there is no penalty for touching pages out of sequence. Also, in a heavily-cached database you should lower both values relative to the CPU parameters, since the cost of fetching a page already in RAM is much smaller than it would normally be.

`cpu_tuple_cost (floating point)`

Sets the planner's estimate of the cost of processing each row during a query. The default is 0.01.

`cpu_index_tuple_cost (floating point)`

Sets the planner's estimate of the cost of processing each index entry during an index scan. The default is 0.005.

`cpu_operator_cost` (floating point)

Sets the planner's estimate of the cost of processing each operator or function executed during a query. The default is 0.0025.

`effective_cache_size` (integer)

Sets the planner's assumption about the effective size of the disk cache that is available to a single query. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. When setting this parameter you should consider both PostgreSQL's shared buffers and the portion of the kernel's disk cache that will be used for PostgreSQL data files. Also, take into account the expected number of concurrent queries on different tables, since they will have to share the available space. This parameter has no effect on the size of shared memory allocated by PostgreSQL, nor does it reserve kernel disk cache; it is used only for estimation purposes. The default is 128 megabytes (128MB).

### 18.6.3. Genetic Query Optimizer

`geqo` (boolean)

Enables or disables genetic query optimization, which is an algorithm that attempts to do query planning without exhaustive searching. This is on by default. The `geqo_threshold` variable provides a more granular way to disable GEQO for certain classes of queries.

`geqo_threshold` (integer)

Use genetic query optimization to plan queries with at least this many `FROM` items involved. (Note that a `FULL OUTER JOIN` construct counts as only one `FROM` item.) The default is 12. For simpler queries it is usually best to use the deterministic, exhaustive planner, but for queries with many tables the deterministic planner takes too long.

`geqo_effort` (integer)

Controls the trade off between planning time and query plan efficiency in GEQO. This variable must be an integer in the range from 1 to 10. The default value is five. Larger values increase the time spent doing query planning, but also increase the likelihood that an efficient query plan will be chosen.

`geqo_effort` doesn't actually do anything directly; it is only used to compute the default values for the other variables that influence GEQO behavior (described below). If you prefer, you can set the other parameters by hand instead.

`geqo_pool_size` (integer)

Controls the pool size used by GEQO. The pool size is the number of individuals in the genetic population. It must be at least two, and useful values are typically 100 to 1000. If it is set to zero (the default setting) then a suitable default is chosen based on `geqo_effort` and the number of tables in the query.

`geqo_generations` (integer)

Controls the number of generations used by GEQO. Generations specifies the number of iterations of the algorithm. It must be at least one, and useful values are in the same range as the pool size. If it is set to zero (the default setting) then a suitable default is chosen based on `geqo_pool_size`.

`geqo_selection_bias` (floating point)

Controls the selection bias used by GEQO. The selection bias is the selective pressure within the population. Values can be from 1.50 to 2.00; the latter is the default.

## 18.6.4. Other Planner Options

`default_statistics_target` (integer)

Sets the default statistics target for table columns that have not had a column-specific target set via `ALTER TABLE SET STATISTICS`. Larger values increase the time needed to do `ANALYZE`, but might improve the quality of the planner's estimates. The default is 10. For more information on the use of statistics by the PostgreSQL query planner, refer to Section 14.2.

`constraint_exclusion` (boolean)

Enables or disables the query planner's use of table constraints to optimize queries. The default is off.

When this parameter is on, the planner compares query conditions with table `CHECK` constraints, and omits scanning tables for which the conditions contradict the constraints. For example:

```
CREATE TABLE parent(key integer, ...);
CREATE TABLE child1000(check (key between 1000 and 1999)) INHERITS(parent);
CREATE TABLE child2000(check (key between 2000 and 2999)) INHERITS(parent);
...
SELECT * FROM parent WHERE key = 2400;
```

With constraint exclusion enabled, this `SELECT` will not scan `child1000` at all. This can improve performance when inheritance is used to build partitioned tables.

Currently, `constraint_exclusion` is disabled by default because the constraint checks are relatively expensive, and in many circumstances will yield no savings. It is recommended to turn this on only if you are actually using partitioned tables designed to take advantage of the feature.

Refer to Section 5.9 for more information on using constraint exclusion and partitioning.

`from_collapse_limit` (integer)

The planner will merge sub-queries into upper queries if the resulting `FROM` list would have no more than this many items. Smaller values reduce planning time but might yield inferior query plans. The default is eight. It is usually wise to keep this less than `geqo_threshold`. For more information see Section 14.3.

`join_collapse_limit` (integer)

The planner will rewrite explicit `JOIN` constructs (except `FULL JOINS`) into lists of `FROM` items whenever a list of no more than this many items would result. Smaller values reduce planning time but might yield inferior query plans.

By default, this variable is set the same as `from_collapse_limit`, which is appropriate for most uses. Setting it to 1 prevents any reordering of explicit `JOINS`. Thus, the explicit join order specified in the query will be the actual order in which the relations are joined. The query planner does not always choose the optimal join order; advanced users can elect to temporarily set this variable to 1, and then specify the join order they desire explicitly. For more information see Section 14.3.

## 18.7. Error Reporting and Logging

### 18.7.1. Where To Log

`log_destination (string)`

PostgreSQL supports several methods for logging server messages, including `stderr`, `csvlog` and `syslog`. On Windows, `eventlog` is also supported. Set this parameter to a list of desired log destinations separated by commas. The default is to log to `stderr` only. This parameter can only be set in the `postgresql.conf` file or on the server command line.

If `csvlog` is included in `log_destination`, log entries are output in “comma separated value” format, which is convenient for loading them into programs. See Section 18.7.4 for details. `logging_collector` must be enabled to generate CSV-format log output.

**Note:** On most Unix systems, you will need to alter the configuration of your system’s syslog daemon in order to make use of the `syslog` option for `log_destination`. PostgreSQL can log to syslog facilities `LOCAL0` through `LOCAL7` (see `syslog_facility`), but the default syslog configuration on most platforms will discard all such messages. You will need to add something like

```
local0.*    /var/log/postgresql
to the syslog daemon's configuration file to make it work.
```

`logging_collector (boolean)`

This parameter allows messages sent to `stderr`, and CSV-format log output, to be captured and redirected into log files. This approach is often more useful than logging to `syslog`, since some types of messages might not appear in `syslog` output (a common example is dynamic-linker failure messages). This parameter can only be set at server start.

`log_directory (string)`

When `logging_collector` is enabled, this parameter determines the directory in which log files will be created. It can be specified as an absolute path, or relative to the cluster data directory. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`log_filename (string)`

When `logging_collector` is enabled, this parameter sets the file names of the created log files. The value is treated as a strftime pattern, so %-escapes can be used to specify time-varying file names. (Note that if there are any time-zone-dependent %-escapes, the computation is done in the zone specified by `log_timezone`.) If no %-escapes are present, PostgreSQL will append the epoch of the new log file’s creation time. For example, if `log_filename` were `server_log`, then the chosen file name would be `server_log.1093827753` for a log starting at Sun Aug 29 19:02:33 2004 MST. This parameter can only be set in the `postgresql.conf` file or on the server command line.

If CSV-format output is enabled in `log_destination`, `.csv` will be appended to the timestamped log file name to create the file name for CSV-format output. (If `log_filename` ends in `.log`, the suffix is replaced instead.) In the case of the example above, the CSV file name will be `server_log.1093827753.csv`.

`log_rotation_age` (integer)

When `logging_collector` is enabled, this parameter determines the maximum lifetime of an individual log file. After this many minutes have elapsed, a new log file will be created. Set to zero to disable time-based creation of new log files. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`log_rotation_size` (integer)

When `logging_collector` is enabled, this parameter determines the maximum size of an individual log file. After this many kilobytes have been emitted into a log file, a new log file will be created. Set to zero to disable size-based creation of new log files. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`log_truncate_on_rotation` (boolean)

When `logging_collector` is enabled, this parameter will cause PostgreSQL to truncate (overwrite), rather than append to, any existing log file of the same name. However, truncation will occur only when a new file is being opened due to time-based rotation, not during server startup or size-based rotation. When off, pre-existing files will be appended to in all cases. For example, using this setting in combination with a `log_filename` like `postgresql-%H.log` would result in generating twenty-four hourly log files and then cyclically overwriting them. This parameter can only be set in the `postgresql.conf` file or on the server command line.

Example: To keep 7 days of logs, one log file per day named `server_log.Mon`, `server_log.Tue`, etc, and automatically overwrite last week's log with this week's log, set `log_filename` to `server_log.%a`, `log_truncate_on_rotation` to on, and `log_rotation_age` to 1440.

Example: To keep 24 hours of logs, one log file per hour, but also rotate sooner if the log file size exceeds 1GB, set `log_filename` to `server_log.%H%M`, `log_truncate_on_rotation` to on, `log_rotation_age` to 60, and `log_rotation_size` to 1000000. Including `%M` in `log_filename` allows any size-driven rotations that might occur to select a file name different from the hour's initial file name.

`syslog_facility` (string)

When logging to syslog is enabled, this parameter determines the syslog “facility” to be used. You can choose from `LOCAL0`, `LOCAL1`, `LOCAL2`, `LOCAL3`, `LOCAL4`, `LOCAL5`, `LOCAL6`, `LOCAL7`; the default is `LOCAL0`. See also the documentation of your system's syslog daemon. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`syslog_ident` (string)

When logging to syslog is enabled, this parameter determines the program name used to identify PostgreSQL messages in syslog logs. The default is `postgres`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

## 18.7.2. When To Log

`client_min_messages` (string)

Controls which message levels are sent to the client. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `LOG`, `NOTICE`, `WARNING`, `ERROR`, `FATAL`, and `PANIC`. Each level includes all the

levels that follow it. The later the level, the fewer messages are sent. The default is `NOTICE`. Note that `LOG` has a different rank here than in `log_min_messages`.

`log_min_messages (string)`

Controls which message levels are written to the server log. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log. The default is `NOTICE`. Note that `LOG` has a different rank here than in `client_min_messages`. Only superusers can change this setting.

`log_error_verbosity (string)`

Controls the amount of detail written in the server log for each message that is logged. Valid values are `TERSE`, `DEFAULT`, and `VERBOSE`, each adding more fields to displayed messages. Only superusers can change this setting.

`log_min_error_statement (string)`

Controls whether or not the SQL statement that causes an error condition will be recorded in the server log. The current SQL statement is included in the log entry for any message of the specified severity or higher. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `ERROR`, which means statements causing errors, log messages, fatal errors, or panics will be logged. To effectively turn off logging of failing statements, set this parameter to `PANIC`. Only superusers can change this setting.

`log_min_duration_statement (integer)`

Causes the duration of each completed statement to be logged if the statement ran for at least the specified number of milliseconds. Setting this to zero prints all statement durations. Minus-one (the default) disables logging statement durations. For example, if you set it to `250ms` then all SQL statements that run 250ms or longer will be logged. Enabling this parameter can be helpful in tracking down unoptimized queries in your applications. Only superusers can change this setting.

For clients using extended query protocol, durations of the Parse, Bind, and Execute steps are logged independently.

**Note:** When using this option together with `log_statement`, the text of statements that are logged because of `log_statement` will not be repeated in the duration log message. If you are not using syslog, it is recommended that you log the PID or session ID using `log_line_prefix` so that you can link the statement message to the later duration message using the process ID or session ID.

`silent_mode (boolean)`

Runs the server silently. If this parameter is set, the server will automatically run in background and any controlling terminals are disassociated. The server's standard output and standard error are redirected to `/dev/null`, so any messages sent to them will be lost. Unless syslog logging is selected or `logging_collector` is enabled, using this parameter is discouraged because it makes it impossible to see error messages. This parameter can only be set at server start.

Table 18-1 explains the message severity levels used by PostgreSQL. If logging output is sent to syslog or Windows' eventlog, the severity levels are translated as shown in the table.

**Table 18-1. Message severity levels**

Severity	Usage	syslog	eventlog
DEBUG1..DEBUG5	Provides successively-more-detailed information for use by developers.	DEBUG	INFORMATION
INFO	Provides information implicitly requested by the user, e.g., output from <code>VACUUM VERBOSE</code> .	INFO	INFORMATION
NOTICE	Provides information that might be helpful to users, e.g., notice of truncation of long identifiers.	NOTICE	INFORMATION
WARNING	Provides warnings of likely problems, e.g., <code>COMMIT</code> outside a transaction block.	NOTICE	WARNING
ERROR	Reports an error that caused the current command to abort.	WARNING	ERROR
LOG	Reports information of interest to administrators, e.g., checkpoint activity.	INFO	INFORMATION
FATAL	Reports an error that caused the current session to abort.	ERR	ERROR
PANIC	Reports an error that caused all database sessions to abort.	CRIT	ERROR

### 18.7.3. What To Log

```

debug_print_parse (boolean)
debug_print_rewritten (boolean)
debug_print_plan (boolean)
debug_pretty_print (boolean)

```

These parameters enable various debugging output to be emitted. For each executed query, they print the resulting parse tree, the query rewriter output, or the execution plan. `debug_pretty_print` indents these displays to produce a more readable but much longer output

format. `client_min_messages` or `log_min_messages` must be `DEBUG1` or lower to actually send this output to the client or the server log, respectively. These parameters are off by default.

`log_checkpoints` (boolean)

Causes checkpoints to be logged in the server log. Some statistics about each checkpoint are included in the log messages, including the number of buffers written and the time spent writing them. This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is off.

`log_connections` (boolean)

Causes each attempted connection to the server to be logged, as well as successful completion of client authentication. This parameter can only be set in the `postgresql.conf` file or on the server command line. The default is off.

**Note:** Some client programs, like `psql`, attempt to connect twice while determining if a password is required, so duplicate “connection received” messages do not necessarily indicate a problem.

`log_disconnections` (boolean)

This outputs a line in the server log similar to `log_connections` but at session termination, and includes the duration of the session. This is off by default. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`log_duration` (boolean)

Causes the duration of every completed statement to be logged. The default is `off`. Only superusers can change this setting.

For clients using extended query protocol, durations of the Parse, Bind, and Execute steps are logged independently.

**Note:** The difference between setting this option and setting `log_min_duration_statement` to zero is that exceeding `log_min_duration_statement` forces the text of the query to be logged, but this option doesn’t. Thus, if `log_duration` is on and `log_min_duration_statement` has a positive value, all durations are logged but the query text is included only for statements exceeding the threshold. This behavior can be useful for gathering statistics in high-load installations.

`log_hostname` (boolean)

By default, connection log messages only show the IP address of the connecting host. Turning on this parameter causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`log_line_prefix` (string)

This is a `printf`-style string that is output at the beginning of each log line. `%` characters begin “escape sequences” that are replaced with status information as outlined below. Unrecognized escapes are ignored. Other characters are copied straight to the log line. Some escapes are only recognized by session processes, and do not apply to background processes such as the main server process. This

parameter can only be set in the `postgresql.conf` file or on the server command line. The default is an empty string.

Escape	Effect	Session only
%u	User name	yes
%d	Database name	yes
%r	Remote host name or IP address, and remote port	yes
%h	Remote host name or IP address	yes
%p	Process ID	no
%t	Time stamp without milliseconds	no
%m	Time stamp with milliseconds	no
%i	Command tag: type of session's current command	yes
%c	Session ID: see below	no
%l	Number of the log line for each session or process, starting at 1	no
%s	Process start time stamp	no
%v	Virtual transaction ID (backendID/localXID)	no
%x	Transaction ID (0 if none is assigned)	no
%q	Produces no output, but tells non-session processes to stop at this point in the string; ignored by session processes	no
%%	Literal %	no

The `%c` escape prints a quasi-unique session identifier, consisting of two 4-byte hexadecimal numbers (without leading zeros) separated by a dot. The numbers are the process start time and the process ID, so `%c` can also be used as a space saving way of printing those items.

**Tip:** If you set a nonempty value for `log_line_prefix`, you should usually make its last character be a space, to provide visual separation from the rest of the log line. A punctuation character could be used too.

**Tip:** Syslog produces its own time stamp and process ID information, so you probably do not want to use those escapes if you are logging to syslog.

`log_lock_waits (boolean)`

Controls whether a log message is produced when a session waits longer than `deadlock_timeout` to acquire a lock. This is useful in determining if lock waits are causing poor performance. The default is `off`.

`log_statement (string)`

Controls which SQL statements are logged. Valid values are `none`, `ddl`, `mod`, and `all`. `ddl` logs all data definition statements, such as `CREATE`, `ALTER`, and `DROP` statements. `mod` logs all `ddl` statements, plus data-modifying statements such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY FROM`. `PREPARE`, `EXECUTE`, and `EXPLAIN ANALYZE` statements are also logged if their contained command is of an appropriate type. For clients using extended query protocol, logging occurs when an `Execute` message is received, and values of the `Bind` parameters are included (with any embedded single-quote marks doubled).

The default is `none`. Only superusers can change this setting.

**Note:** Statements that contain simple syntax errors are not logged even by the `log_statement = all` setting, because the log message is emitted only after basic parsing has been done to determine the statement type. In the case of extended query protocol, this setting likewise does not log statements that fail before the `Execute` phase (i.e., during parse analysis or planning). Set `log_min_error_statement` to `ERROR` (or lower) to log such statements.

`log_temp_files (integer)`

Controls whether temporary files are logged when deleted. Temporary files can be created for sorts, hashes, and temporary query results. A value of zero logs all temporary files, and positive values log only files whose size is equal or greater than the specified number of kilobytes. The default is `-1`, which disables this logging.

`log_timezone (string)`

Sets the time zone used for timestamps written in the log. Unlike `timezone`, this value is cluster-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone. See Section 8.5.3 for more information. This parameter can only be set in the `postgresql.conf` file or on the server command line.

### 18.7.4. Using CSV-Format Log Output

Including `csvlog` in the `log_destination` list provides a convenient way to import log files into a database table. This option emits log lines in comma-separated-value format, with these columns: timestamp with milliseconds, user name, database name, process ID, host:port number, session ID, per-session or -process line number, command tag, session start time, virtual transaction ID, regular transaction id, error severity, SQL state code, error message, error message detail, hint, internal query that led to the error (if any), character count of the error position thereof, error context, user query that led to the error (if any and enabled by `log_min_error_statement`), character count of the error position thereof, location of the error in the PostgreSQL source code (if `log_error_verbosity` is set to `verbose`). Here is a sample table definition for storing CSV-format log output:

```
CREATE TABLE postgres_log
```

```
(
  log_time timestamp(3) with time zone,
  user_name text,
  database_name text,
  process_id integer,
  connection_from text,
  session_id text,
  session_line_num bigint,
  command_tag text,
  session_start_time timestamp with time zone,
  virtual_transaction_id text,
  transaction_id bigint,
  error_severity text,
  sql_state_code text,
  message text,
  detail text,
  hint text,
  internal_query text,
  internal_query_pos integer,
  context text,
  query text,
  query_pos integer,
  location text,
  PRIMARY KEY (session_id, session_line_num)
);
```

To import a log file into this table, use the `COPY FROM` command:

```
COPY postgres_log FROM '/full/path/to/logfile.csv' WITH csv;
```

There are a few things you need to do to simplify importing CSV log files easily and automatically:

1. Set `log_filename` and `log_rotation_age` to provide a consistent, predictable naming scheme for your log files. This lets you predict what the file name will be and know when an individual log file is complete and therefore ready to be imported.
2. Set `log_rotation_size` to 0 to disable size-based log rotation, as it makes the log file name difficult to predict.
3. Set `log_truncate_on_rotation` to `on` so that old log data isn't mixed with the new in the same file.
4. The table definition above includes a primary key specification. This is useful to protect against accidentally importing the same information twice. The `COPY` command commits all of the data it imports at one time, so any error will cause the entire import to fail. If you import a partial log file and later import the file again when it is complete, the primary key violation will cause the import to fail. Wait until the log is complete and closed before importing. This procedure will also protect against accidentally importing a partial line that hasn't been completely written, which would also cause `COPY` to fail.

## 18.8. Run-Time Statistics

### 18.8.1. Query and Index Statistics Collector

These parameters control server-wide statistics collection features. When statistics collection is enabled, the data that is produced can be accessed via the `pg_stat` and `pg_statio` family of system views. Refer to Chapter 26 for more information.

`track_activities` (boolean)

Enables the collection of information on the currently executing command of each session, along with the time at which that command began execution. This parameter is on by default. Note that even when enabled, this information is not visible to all users, only to superusers and the user owning the session being reported on; so it should not represent a security risk. Only superusers can change this setting.

`track_counts` (boolean)

Enables collection of statistics on database activity. This parameter is on by default, because the autovacuum daemon needs the collected information. Only superusers can change this setting.

`update_process_title` (boolean)

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the `ps` command, or in Windows by using the Process Explorer. Only superusers can change this setting.

### 18.8.2. Statistics Monitoring

`log_statement_stats` (boolean)

`log_parser_stats` (boolean)

`log_planner_stats` (boolean)

`log_executor_stats` (boolean)

For each query, write performance statistics of the respective module to the server log. This is a crude profiling instrument. `log_statement_stats` reports total statement statistics, while the others report per-module statistics. `log_statement_stats` cannot be enabled together with any of the per-module options. All of these options are disabled by default. Only superusers can change these settings.

## 18.9. Automatic Vacuuming

These settings control the behavior of the *autovacuum* feature. Refer to Section 23.1.4 for more information.

`autovacuum (boolean)`

Controls whether the server should run the autovacuum launcher daemon. This is on by default; however, `track_counts` must also be turned on for autovacuum to work. This parameter can only be set in the `postgresql.conf` file or on the server command line.

Note that even when this parameter is disabled, the system will launch autovacuum processes if necessary to prevent transaction ID wraparound. See Section 23.1.3 for more information.

`log_autovacuum_min_duration (integer)`

Causes each action executed by autovacuum to be logged if it ran for at least the specified number of milliseconds. Setting this to zero logs all autovacuum actions. Minus-one (the default) disables logging autovacuum actions. For example, if you set this to `250ms` then all automatic vacuums and analyzes that run 250ms or longer will be logged. Enabling this parameter can be helpful in tracking autovacuum activity. This setting can only be set in the `postgresql.conf` file or on the server command line.

`autovacuum_max_workers (integer)`

Specifies the maximum number of autovacuum processes (other than the autovacuum launcher) which may be running at any one time. The default is three. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`autovacuum_naptime (integer)`

Specifies the minimum delay between autovacuum runs on any given database. In each round the daemon examines the database and issues `VACUUM` and `ANALYZE` commands as needed for tables in that database. The delay is measured in seconds, and the default is one minute (1m). This parameter can only be set in the `postgresql.conf` file or on the server command line.

`autovacuum_vacuum_threshold (integer)`

Specifies the minimum number of updated or deleted tuples needed to trigger a `VACUUM` in any one table. The default is 50 tuples. This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

`autovacuum_analyze_threshold (integer)`

Specifies the minimum number of inserted, updated or deleted tuples needed to trigger an `ANALYZE` in any one table. The default is 50 tuples. This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

`autovacuum_vacuum_scale_factor (floating point)`

Specifies a fraction of the table size to add to `autovacuum_vacuum_threshold` when deciding whether to trigger a `VACUUM`. The default is 0.2 (20% of table size). This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

`autovacuum_analyze_scale_factor` (floating point)

Specifies a fraction of the table size to add to `autovacuum_analyze_threshold` when deciding whether to trigger an `ANALYZE`. The default is 0.1 (10% of table size). This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

`autovacuum_freeze_max_age` (integer)

Specifies the maximum age (in transactions) that a table's `pg_class.relFrozenxid` field can attain before a `VACUUM` operation is forced to prevent transaction ID wraparound within the table. Note that the system will launch autovacuum processes to prevent wraparound even when autovacuum is otherwise disabled. The default is 200 million transactions. This parameter can only be set at server start, but the setting can be reduced for individual tables by entries in `pg_autovacuum`. For more information see Section 23.1.3.

`autovacuum_vacuum_cost_delay` (integer)

Specifies the cost delay value that will be used in automatic `VACUUM` operations. If `-1` is specified, the regular `vacuum_cost_delay` value will be used. The default value is 20 milliseconds. This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

`autovacuum_vacuum_cost_limit` (integer)

Specifies the cost limit value that will be used in automatic `VACUUM` operations. If `-1` is specified (which is the default), the regular `vacuum_cost_limit` value will be used. Note that the value is distributed proportionally among the running autovacuum workers, if there is more than one, so that the sum of the limits of each worker never exceeds the limit on this variable. This parameter can only be set in the `postgresql.conf` file or on the server command line. This setting can be overridden for individual tables by entries in `pg_autovacuum`.

## 18.10. Client Connection Defaults

### 18.10.1. Statement Behavior

`search_path` (string)

This variable specifies the order in which schemas are searched when an object (table, data type, function, etc.) is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. An object that is not in any of the schemas in the search path can only be referenced by specifying its containing schema with a qualified (dotted) name.

The value for `search_path` has to be a comma-separated list of schema names. If one of the list items is the special value `$user`, then the schema having the name returned by `SESSION_USER` is substituted, if there is such a schema. (If not, `$user` is ignored.)

The system catalog schema, `pg_catalog`, is always searched, whether it is mentioned in the path or not. If it is mentioned in the path then it will be searched in the specified order. If `pg_catalog` is not in the path then it will be searched *before* searching any of the path items.

Likewise, the current session's temporary-table schema, `pg_temp_nnn`, is always searched if it exists. It can be explicitly listed in the path by using the alias `pg_temp`. If it is not listed in the path then it is searched first (before even `pg_catalog`). However, the temporary schema is only searched for relation (table, view, sequence, etc) and data type names. It will never be searched for function or operator names.

When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. An error is reported if the search path is empty.

The default value for this parameter is `'"$user", public'` (where the second part will be ignored if there is no schema named `public`). This supports shared use of a database (where no users have private schemas, and all share use of `public`), private per-user schemas, and combinations of these. Other effects can be obtained by altering the default search path setting, either globally or per-user.

The current effective value of the search path can be examined via the SQL function `current_schemas()`. This is not quite the same as examining the value of `search_path`, since `current_schemas()` shows how the requests appearing in `search_path` were resolved.

For more information on schema handling, see Section 5.7.

`default_tablespace (string)`

This variable specifies the default tablespace in which to create objects (tables and indexes) when a `CREATE` command does not explicitly specify a tablespace.

The value is either the name of a tablespace, or an empty string to specify using the default tablespace of the current database. If the value does not match the name of any existing tablespace, PostgreSQL will automatically use the default tablespace of the current database. If a nondefault tablespace is specified, the user must have `CREATE` privilege for it, or creation attempts will fail.

This variable is not used for temporary tables; for them, `temp_tablespaces` is consulted instead.

For more information on tablespaces, see Section 20.6.

`temp_tablespaces (string)`

This variable specifies tablespace(s) in which to create temporary objects (temp tables and indexes on temp tables) when a `CREATE` command does not explicitly specify a tablespace. Temporary files for purposes such as sorting large data sets are also created in these tablespace(s).

The value is a list of names of tablespaces. When there is more than one name in the list, PostgreSQL chooses a random member of the list each time a temporary object is to be created; except that within a transaction, successively created temporary objects are placed in successive tablespaces from the list. If the selected element of the list is an empty string, PostgreSQL will automatically use the default tablespace of the current database instead.

When `temp_tablespaces` is set interactively, specifying a nonexistent tablespace is an error, as is specifying a tablespace for which the user does not have `CREATE` privilege. However, when using a previously set value, nonexistent tablespaces are ignored, as are tablespaces for which the user lacks `CREATE` privilege. In particular, this rule applies when using a value set in `postgresql.conf`.

The default value is an empty string, which results in all temporary objects being created in the default tablespace of the current database.

See also `default_tablespace`.

`check_function_bodies (boolean)`

This parameter is normally on. When set to `off`, it disables validation of the function body string during *CREATE FUNCTION*. Disabling validation is occasionally useful to avoid problems such as forward references when restoring function definitions from a dump.

`default_transaction_isolation (string)`

Each SQL transaction has an isolation level, which can be either “read uncommitted”, “read committed”, “repeatable read”, or “serializable”. This parameter controls the default isolation level of each new transaction. The default is “read committed”.

Consult Chapter 13 and *SET TRANSACTION* for more information.

`default_transaction_read_only (boolean)`

A read-only SQL transaction cannot alter non-temporary tables. This parameter controls the default read-only status of each new transaction. The default is `off` (read/write).

Consult *SET TRANSACTION* for more information.

`session_replication_role (string)`

Controls firing of replication-related triggers and rules for the current session. Setting this variable requires superuser privilege and results in discarding any previously cached query plans. Possible values are `origin` (the default), `replica` and `local`. See *ALTER TABLE* for more information.

`statement_timeout (integer)`

Abort any statement that takes over the specified number of milliseconds, starting from the time the command arrives at the server from the client. If `log_min_error_statement` is set to `ERROR` or lower, the statement that timed out will also be logged. A value of zero (the default) turns off the limitation.

Setting `statement_timeout` in `postgresql.conf` is not recommended because it affects all sessions.

`vacuum_freeze_min_age (integer)`

Specifies the cutoff age (in transactions) that `VACUUM` should use to decide whether to replace transaction IDs with `FrozenXID` while scanning a table. The default is 100 million transactions. Although users can set this value anywhere from zero to one billion, `VACUUM` will silently limit the effective value to half the value of `autovacuum_freeze_max_age`, so that there is not an unreasonably short time between forced autovacuums. For more information see Section 23.1.3.

`xmlbinary (string)`

Sets how binary values are to be encoded in XML. This applies for example when `bytea` values are converted to XML by the functions `xmlelement` or `xmlforest`. Possible values are `base64` and `hex`, which are both defined in the XML Schema standard. The default is `base64`. For further information about XML-related functions, see Section 9.14.

The actual choice here is mostly a matter of taste, constrained only by possible restrictions in client applications. Both methods support all possible values, although the hex encoding will be somewhat larger than the base64 encoding.

`xmloption (string)`

Sets whether `DOCUMENT` or `CONTENT` is implicit when converting between XML and character string values. See Section 8.13 for a description of this. Valid values are `DOCUMENT` and `CONTENT`. The default is `CONTENT`.

According to the SQL standard, the command to set this option is

```
SET XML OPTION { DOCUMENT | CONTENT };
```

This syntax is also available in PostgreSQL.

## 18.10.2. Locale and Formatting

`DateStyle (string)`

Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. For historical reasons, this variable contains two independent components: the output format specification (`ISO`, `Postgres`, `SQL`, or `German`) and the input/output specification for year/month/day ordering (`DMY`, `MDY`, or `YMD`). These can be set separately or together. The keywords `Euro` and `European` are synonyms for `DMY`; the keywords `US`, `NonEuro`, and `NonEuropean` are synonyms for `MDY`. See Section 8.5 for more information. The built-in default is `ISO`, `MDY`, but `initdb` will initialize the configuration file with a setting that corresponds to the behavior of the chosen `lc_time` locale.

`timezone (string)`

Sets the time zone for displaying and interpreting time stamps. The default is `unknown`, which means to use whatever the system environment specifies as the time zone. See Section 8.5.3 for more information.

`timezone_abbreviations (string)`

Sets the collection of time zone abbreviations that will be accepted by the server for datetime input. The default is `'Default'`, which is a collection that works in most of the world; there are also `'Australia'` and `'India'`, and other collections can be defined for a particular installation. See Appendix B for more information.

`extra_float_digits (integer)`

This parameter adjusts the number of digits displayed for floating-point values, including `float4`, `float8`, and geometric data types. The parameter value is added to the standard number of digits (`FLT_DIG` or `DBL_DIG` as appropriate). The value can be set as high as 2, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.

`client_encoding (string)`

Sets the client-side encoding (character set). The default is to use the database encoding.

`lc_messages (string)`

Sets the language in which messages are displayed. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

Only superusers can change this setting, because it affects the messages sent to the server log as well as to the client.

`lc_monetary (string)`

Sets the locale to use for formatting monetary amounts, for example with the `to_char` family of functions. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

`lc_numeric (string)`

Sets the locale to use for formatting numbers, for example with the `to_char` family of functions. Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

`lc_time (string)`

Sets the locale to use for formatting date and time values. (Currently, this setting does nothing, but it might in the future.) Acceptable values are system-dependent; see Section 22.1 for more information. If this variable is set to the empty string (which is the default) then the value is inherited from the execution environment of the server in a system-dependent way.

`default_text_search_config (string)`

Selects the text search configuration that is used by those variants of the text search functions that do not have an explicit argument specifying the configuration. See Chapter 12 for further information. The built-in default is `pg_catalog.simple`, but `initdb` will initialize the configuration file with a setting that corresponds to the chosen `lc_ctype` locale, if a configuration matching that locale can be identified.

### 18.10.3. Other Defaults

`explain_pretty_print (boolean)`

Determines whether `EXPLAIN VERBOSE` uses the indented or non-indented format for displaying detailed query-tree dumps. The default is `on`.

`dynamic_library_path (string)`

If a dynamically loadable module needs to be opened and the file name specified in the `CREATE FUNCTION` or `LOAD` command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file.

The value for `dynamic_library_path` has to be a list of absolute directory paths separated by colons (or semi-colons on Windows). If a list element starts with the special string `$libdir`, the compiled-in PostgreSQL package library directory is substituted for `$libdir`. This is where the modules provided by the standard PostgreSQL distribution are installed. (Use `pg_config --pkglibdir` to find out the name of this directory.) For example:

`dynamic_library_path = '/usr/local/lib/postgresql:/home/my_project/lib:$libdir'`  
 or, in a Windows environment:

`dynamic_library_path = 'C:\tools\postgresql;H:\my_project\lib;$libdir'`

The default value for this parameter is `'$libdir'`. If the value is set to an empty string, the automatic path search is turned off.

This parameter can be changed at run time by superusers, but a setting done that way will only persist until the end of the client connection, so this method should be reserved for development purposes.

The recommended way to set this parameter is in the `postgresql.conf` configuration file.

`gin_fuzzy_search_limit (integer)`

Soft upper limit of the size of the set returned by GIN index. For more information see Section 52.4.

`local_preload_libraries (string)`

This variable specifies one or more shared libraries that are to be preloaded at connection start. If more than one library is to be loaded, separate their names with commas. This parameter cannot be changed after the start of a particular session.

Because this is not a superuser-only option, the libraries that can be loaded are restricted to those appearing in the `plugins` subdirectory of the installation's standard library directory. (It is the database administrator's responsibility to ensure that only "safe" libraries are installed there.) Entries in `local_preload_libraries` can specify this directory explicitly, for example `$libdir/plugins/mylib`, or just specify the library name — `mylib` would have the same effect as `$libdir/plugins/mylib`.

There is no performance advantage to loading a library at session start rather than when it is first used. Rather, the intent of this feature is to allow debugging or performance-measurement libraries to be loaded into specific sessions without an explicit `LOAD` command being given. For example, debugging could be enabled for all sessions under a given user name by setting this parameter with `ALTER USER SET`.

If a specified library is not found, the connection attempt will fail.

Every PostgreSQL-supported library has a "magic block" that is checked to guarantee compatibility. For this reason, non-PostgreSQL libraries cannot be loaded in this way.

## 18.11. Lock Management

`deadlock_timeout (integer)`

This is the amount of time, in milliseconds, to wait on a lock before checking to see if there is a deadlock condition. The check for deadlock is relatively slow, so the server doesn't run it every time it waits for a lock. We optimistically assume that deadlocks are not common in production applications and just wait on the lock for a while before starting the check for a deadlock. Increasing this value reduces the amount of time wasted in needless deadlock checks, but slows down reporting of real deadlock errors. The default is one second (1s), which is probably about the smallest value you would want in practice. On a heavily loaded server you might want to raise it. Ideally the setting

should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

When `log_lock_waits` is set, this parameter also determines the length of time to wait before a log message is issued about the lock wait. If you are trying to investigate locking delays you might want to set a shorter than normal `deadlock_timeout`.

`max_locks_per_transaction (integer)`

The shared lock table is created to track locks on `max_locks_per_transaction * (max_connections + max_prepared_transactions)` objects (e.g. tables); hence, no more than this many distinct objects can be locked at any one time. This parameter controls the average number of object locks allocated for each transaction; individual transactions can lock more objects as long as the locks of all transactions fit in the lock table. This is *not* the number of rows that can be locked; that value is unlimited. The default, 64, has historically proven sufficient, but you might need to raise this value if you have clients that touch many different tables in a single transaction. This parameter can only be set at server start.

Increasing this parameter might cause PostgreSQL to request more System V shared memory than your operating system's default configuration allows. See Section 17.4.1 for information on how to adjust those parameters, if necessary.

## 18.12. Version and Platform Compatibility

### 18.12.1. Previous PostgreSQL Versions

`add_missing_from (boolean)`

When on, tables that are referenced by a query will be automatically added to the `FROM` clause if not already present. This behavior does not comply with the SQL standard and many people dislike it because it can mask mistakes (such as referencing a table where you should have referenced its alias). The default is `off`. This variable can be enabled for compatibility with releases of PostgreSQL prior to 8.1, where this behavior was allowed by default.

Note that even when this variable is enabled, a warning message will be emitted for each implicit `FROM` entry referenced by a query. Users are encouraged to update their applications to not rely on this behavior, by adding all tables referenced by a query to the query's `FROM` clause (or its `USING` clause in the case of `DELETE`).

`array_nulls (boolean)`

This controls whether the array input parser recognizes unquoted `NULL` as specifying a null array element. By default, this is `on`, allowing array values containing null values to be entered. However, PostgreSQL versions before 8.2 did not support null values in arrays, and therefore would treat `NULL` as specifying a normal array element with the string value "NULL". For backwards compatibility with applications that require the old behavior, this variable can be turned `off`.

Note that it is possible to create array values containing null values even when this variable is `off`.

`backslash_quote (string)`

This controls whether a quote mark can be represented by `\'` in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (`"`) but PostgreSQL has historically also accepted `\'`. However, use of `\'` creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII `\`. If client-side code does escaping incorrectly then a SQL-injection attack is possible. This risk can be prevented by making the server reject queries in which a quote mark appears to be escaped by a backslash. The allowed values of `backslash_quote` are `on` (allow `\'` always), `off` (reject always), and `safe_encoding` (allow only if client encoding does not allow ASCII `\` within a multibyte character). `safe_encoding` is the default setting.

Note that in a standard-conforming string literal, `\` just means `\` anyway. This parameter affects the handling of non-standard-conforming literals, including escape string syntax (`E' . . .'`).

`default_with_oids (boolean)`

This controls whether `CREATE TABLE` and `CREATE TABLE AS` include an OID column in newly-created tables, if neither `WITH OIDS` nor `WITHOUT OIDS` is specified. It also determines whether OIDs will be included in tables created by `SELECT INTO`. In PostgreSQL 8.1 `default_with_oids` is `off` by default; in prior versions of PostgreSQL, it was `on` by default.

The use of OIDs in user tables is considered deprecated, so most installations should leave this variable disabled. Applications that require OIDs for a particular table should specify `WITH OIDS` when creating the table. This variable can be enabled for compatibility with old applications that do not follow this behavior.

`escape_string_warning (boolean)`

When `on`, a warning is issued if a backslash (`\`) appears in an ordinary string literal (`' . . .'` syntax) and `standard_conforming_strings` is `off`. The default is `on`.

Applications that wish to use backslash as escape should be modified to use escape string syntax (`E' . . .'`), because the default behavior of ordinary strings will change in a future release for SQL compatibility. This variable can be enabled to help detect applications that will break.

`regex_flavor (string)`

The regular expression “flavor” can be set to `advanced`, `extended`, or `basic`. The default is `advanced`. The `extended` setting might be useful for exact backwards compatibility with pre-7.4 releases of PostgreSQL. See Section 9.7.3.1 for details.

`sql_inheritance (boolean)`

This controls the inheritance semantics. If turned `off`, subtables are not included by various commands by default; basically an implied `ONLY` key word. This was added for compatibility with releases prior to 7.1. See Section 5.8 for more information.

`standard_conforming_strings (boolean)`

This controls whether ordinary string literals (`' . . .'`) treat backslashes literally, as specified in the SQL standard. The default is currently `off`, causing PostgreSQL to have its historical behavior of treating backslashes as escape characters. The default will change to `on` in a future release to improve compatibility with the standard. Applications can check this parameter to determine how string literals will be processed. The presence of this parameter can also be taken as an indication that the

escape string syntax (`E' . . .'`) is supported. Escape string syntax should be used if an application desires backslashes to be treated as escape characters.

`synchronize_seqscans` (boolean)

This allows sequential scans of large tables to synchronize with each other, so that concurrent scans read the same block at about the same time and hence share the I/O workload. When this is enabled, a scan might start in the middle of the table and then “wrap around” the end to cover all rows, so as to synchronize with the activity of scans already in progress. This can result in unpredictable changes in the row ordering returned by queries that have no `ORDER BY` clause. Setting this parameter to `off` ensures the pre-8.3 behavior in which a sequential scan always starts from the beginning of the table. The default is `on`.

## 18.12.2. Platform and Client Compatibility

`transform_null_equals` (boolean)

When `on`, expressions of the form `expr = NULL` (or `NULL = expr`) are treated as `expr IS NULL`, that is, they return true if `expr` evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of `expr = NULL` is to always return null (unknown). Therefore this parameter defaults to `off`.

However, filtered forms in Microsoft Access generate queries that appear to use `expr = NULL` to test for null values, so if you use that interface to access the database you might want to turn this option `on`. Since expressions of the form `expr = NULL` always return the null value (using the correct interpretation) they are not very useful and do not appear often in normal applications, so this option does little harm in practice. But new users are frequently confused about the semantics of expressions involving null values, so this option is not `on` by default.

Note that this option only affects the exact form `= NULL`, not other comparison operators or other expressions that are computationally equivalent to some expression involving the equals operator (such as `IN`). Thus, this option is not a general fix for bad programming.

Refer to Section 9.2 for related information.

## 18.13. Preset Options

The following “parameters” are read-only, and are determined when PostgreSQL is compiled or when it is installed. As such, they have been excluded from the sample `postgresql.conf` file. These options report various aspects of PostgreSQL behavior that might be of interest to certain applications, particularly administrative front-ends.

`block_size` (integer)

Reports the size of a disk block. It is determined by the value of `BLCKSZ` when building the server. The default value is 8192 bytes. The meaning of some configuration variables (such as `shared_buffers`) is influenced by `block_size`. See Section 18.4 for information.

`integer_datetimes (boolean)`

Reports whether PostgreSQL was built with support for 64-bit-integer dates and times. It is set by configuring with `--enable-integer-datetimes` when building PostgreSQL. The default value is off.

`lc_collate (string)`

Reports the locale in which sorting of textual data is done. See Section 22.1 for more information. The value is determined when the database cluster is initialized.

`lc_ctype (string)`

Reports the locale that determines character classifications. See Section 22.1 for more information. The value is determined when the database cluster is initialized. Ordinarily this will be the same as `lc_collate`, but for special applications it might be set differently.

`max_function_args (integer)`

Reports the maximum number of function arguments. It is determined by the value of `FUNC_MAX_ARGS` when building the server. The default value is 100 arguments.

`max_identifier_length (integer)`

Reports the maximum identifier length. It is determined as one less than the value of `NAMEDATALEN` when building the server. The default value of `NAMEDATALEN` is 64; therefore the default `max_identifier_length` is 63 bytes.

`max_index_keys (integer)`

Reports the maximum number of index keys. It is determined by the value of `INDEX_MAX_KEYS` when building the server. The default value is 32 keys.

`server_encoding (string)`

Reports the database encoding (character set). It is determined when the database is created. Ordinarily, clients need only be concerned with the value of `client_encoding`.

`server_version (string)`

Reports the version number of the server. It is determined by the value of `PG_VERSION` when building the server.

`server_version_num (integer)`

Reports the version number of the server as an integer. It is determined by the value of `PG_VERSION_NUM` when building the server.

## 18.14. Customized Options

This feature was designed to allow parameters not normally known to PostgreSQL to be added by add-on modules (such as procedural languages). This allows add-on modules to be configured in the standard ways.

`custom_variable_classes (string)`

This variable specifies one or several class names to be used for custom variables, in the form of a comma-separated list. A custom variable is a variable not normally known to PostgreSQL proper but used by some add-on module. Such variables must have names consisting of a class name, a dot, and a variable name. `custom_variable_classes` specifies all the class names in use in a particular installation. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The difficulty with setting custom variables in `postgresql.conf` is that the file must be read before add-on modules have been loaded, and so custom variables would ordinarily be rejected as unknown. When `custom_variable_classes` is set, the server will accept definitions of arbitrary variables within each specified class. These variables will be treated as placeholders and will have no function until the module that defines them is loaded. When a module for a specific class is loaded, it will add the proper variable definitions for its class name, convert any placeholder values according to those definitions, and issue warnings for any placeholders of its class that remain (which presumably would be misspelled configuration variables).

Here is an example of what `postgresql.conf` might contain when using custom variables:

```
custom_variable_classes = 'plr,plperl'
plr.path = '/usr/lib/R'
plperl.use_strict = true
plrby.use_strict = true          # generates error: unknown class name
```

## 18.15. Developer Options

The following parameters are intended for work on the PostgreSQL source, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. As such, they have been excluded from the sample `postgresql.conf` file. Note that many of these parameters require special source compilation flags to work at all.

`allow_system_table_mods (boolean)`

Allows modification of the structure of system tables. This is used by `initdb`. This parameter can only be set at server start.

`debug_assertions (boolean)`

Turns on various assertion checks. This is a debugging aid. If you are experiencing strange problems or crashes you might want to turn this on, as it might expose programming mistakes. To use this parameter, the macro `USE_ASSERT_CHECKING` must be defined when PostgreSQL is built (accomplished by the `configure` option `--enable-cassert`). Note that `debug_assertions` defaults to on if PostgreSQL has been built with assertions enabled.

`ignore_system_indexes (boolean)`

Ignore system indexes when reading system tables (but still update the indexes when modifying the tables). This is useful when recovering from damaged system indexes. This parameter cannot be changed after session start.

`post_auth_delay (integer)`

If nonzero, a delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger. This parameter cannot be changed after session start.

`pre_auth_delay (integer)`

If nonzero, a delay of this many seconds occurs just after a new server process is forked, before it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger to trace down misbehavior in authentication. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`trace_notify (boolean)`

Generates a great amount of debugging output for the `LISTEN` and `NOTIFY` commands. `client_min_messages` or `log_min_messages` must be `DEBUG1` or lower to send this output to the client or server log, respectively.

`trace_sort (boolean)`

If on, emit information about resource usage during sort operations. This parameter is only available if the `TRACE_SORT` macro was defined when PostgreSQL was compiled. (However, `TRACE_SORT` is currently defined by default.)

`trace_locks (boolean)`

`trace_lwlocks (boolean)`

`trace_userlocks (boolean)`

`trace_lock_oidmin (boolean)`

`trace_lock_table (boolean)`

`debug_deadlocks (boolean)`

`log_btree_build_stats (boolean)`

Various other code tracing and debugging options.

`wal_debug (boolean)`

If on, emit WAL-related debugging output. This parameter is only available if the `WAL_DEBUG` macro was defined when PostgreSQL was compiled.

`zero_damaged_pages (boolean)`

Detection of a damaged page header normally causes PostgreSQL to report an error, aborting the current command. Setting `zero_damaged_pages` to on causes the system to instead report a warning, zero out the damaged page, and continue processing. This behavior *will destroy data*, namely all the rows on the damaged page. But it allows you to get past the error and retrieve rows from any undamaged pages that might be present in the table. So it is useful for recovering data if corruption has occurred due to hardware or software error. You should generally not set this on until you have given up hope of recovering data from the damaged page(s) of a table. The default setting is `off`, and it can only be changed by a superuser.

## 18.16. Short Options

For convenience there are also single letter command-line option switches available for some parameters. They are described in Table 18-2. Some of these options exist for historical reasons, and their presence as a single-letter option does not necessarily indicate an endorsement to use the option heavily.

**Table 18-2. Short option key**

Short option	Equivalent
-A <i>x</i>	debug_assertions = <i>x</i>
-B <i>x</i>	shared_buffers = <i>x</i>
-d <i>x</i>	log_min_messages = DEBUG <i>x</i>
-e	datestyle = euro
-fb, -fh, -fi, -fm, -fn, -fs, -ft	enable_bitmapscan = off, enable_hashjoin = off, enable_indexscan = off, enable_mergejoin = off, enable_nestloop = off, enable_seqscan = off, enable_tidscan = off
-F	fsync = off
-h <i>x</i>	listen_addresses = <i>x</i>
-i	listen_addresses = '*'
-k <i>x</i>	unix_socket_directory = <i>x</i>
-l	ssl = on
-N <i>x</i>	max_connections = <i>x</i>
-O	allow_system_table_mods = on
-p <i>x</i>	port = <i>x</i>
-P	ignore_system_indexes = on
-s	log_statement_stats = on
-S <i>x</i>	work_mem = <i>x</i>
-tpa, -tpl, -te	log_parser_stats = on, log_planner_stats = on, log_executor_stats = on
-W <i>x</i>	post_auth_delay = <i>x</i>

# Chapter 19. Database Roles and Privileges

PostgreSQL manages database access permissions using the concept of *roles*. A role can be thought of as either a database user, or a group of database users, depending on how the role is set up. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control who has access to which objects. Furthermore, it is possible to grant *membership* in a role to another role, thus allowing the member role use of privileges assigned to the role it is a member of.

The concept of roles subsumes the concepts of “users” and “groups”. In PostgreSQL versions before 8.1, users and groups were distinct kinds of entities, but now there are only roles. Any role can act as a user, a group, or both.

This chapter describes how to create and manage roles and introduces the privilege system. More information about the various types of database objects and the effects of privileges can be found in Chapter 5.

## 19.1. Database Roles

Database roles are conceptually completely separate from operating system users. In practice it might be convenient to maintain a correspondence, but this is not required. Database roles are global across a database cluster installation (and not per individual database). To create a role use the *CREATE ROLE* SQL command:

```
CREATE ROLE name;
```

*name* follows the rules for SQL identifiers: either unadorned without special characters, or double-quoted. (In practice, you will usually want to add additional options, such as *LOGIN*, to the command. More details appear below.) To remove an existing role, use the analogous *DROP ROLE* command:

```
DROP ROLE name;
```

For convenience, the programs *createuser* and *dropuser* are provided as wrappers around these SQL commands that can be called from the shell command line:

```
createuser name  
dropuser name
```

To determine the set of existing roles, examine the *pg\_roles* system catalog, for example

```
SELECT rolname FROM pg_roles;
```

The *psql* program’s *\du* meta-command is also useful for listing the existing roles.

In order to bootstrap the database system, a freshly initialized system always contains one predefined role. This role is always a “superuser”, and by default (unless altered when running *initdb*) it will have the same name as the operating system user that initialized the database cluster. Customarily, this role will be named *postgres*. In order to create more roles you first have to connect as this initial role.

Every connection to the database server is made in the name of some particular role, and this role determines the initial access privileges for commands issued on that connection. The role name to use for a particular database connection is indicated by the client that is initiating the connection request in an application-specific fashion. For example, the `psql` program uses the `-U` command line option to indicate the role to connect as. Many applications assume the name of the current operating system user by default (including `createuser` and `psql`). Therefore it is often convenient to maintain a naming correspondence between roles and operating system users.

The set of database roles a given client connection can connect as is determined by the client authentication setup, as explained in Chapter 21. (Thus, a client is not necessarily limited to connect as the role with the same name as its operating system user, just as a person's login name need not match her real name.) Since the role identity determines the set of privileges available to a connected client, it is important to carefully configure this when setting up a multiuser environment.

## 19.2. Role Attributes

A database role can have a number of attributes that define its privileges and interact with the client authentication system.

### login privilege

Only roles that have the `LOGIN` attribute can be used as the initial role name for a database connection. A role with the `LOGIN` attribute can be considered the same thing as a “database user”. To create a role with login privilege, use either:

```
CREATE ROLE name LOGIN;
CREATE USER name;
(CREATE USER is equivalent to CREATE ROLE except that CREATE USER assumes LOGIN by default,
while CREATE ROLE does not.)
```

### superuser status

A database superuser bypasses all permission checks. This is a dangerous privilege and should not be used carelessly; it is best to do most of your work as a role that is not a superuser. To create a new database superuser, use `CREATE ROLE name SUPERUSER`. You must do this as a role that is already a superuser.

### database creation

A role must be explicitly given permission to create databases (except for superusers, since those bypass all permission checks). To create such a role, use `CREATE ROLE name CREATEDB`.

### role creation

A role must be explicitly given permission to create more roles (except for superusers, since those bypass all permission checks). To create such a role, use `CREATE ROLE name CREATEROLE`. A role with `CREATEROLE` privilege can alter and drop other roles, too, as well as grant or revoke membership in them. However, to create, alter, drop, or change membership of a superuser role, superuser status is required; `CREATEROLE` is not sufficient for that.

password

A password is only significant if the client authentication method requires the user to supply a password when connecting to the database. The `password`, `md5`, and `crypt` authentication methods make use of passwords. Database passwords are separate from operating system passwords. Specify a password upon role creation with `CREATE ROLE name PASSWORD 'string'`.

A role's attributes can be modified after creation with `ALTER ROLE`. See the reference pages for the `CREATE ROLE` and `ALTER ROLE` commands for details.

**Tip:** It is good practice to create a role that has the `CREATEDB` and `CREATEROLE` privileges, but is not a superuser, and then use this role for all routine management of databases and roles. This approach avoids the dangers of operating as a superuser for tasks that do not really require it.

A role can also have role-specific defaults for many of the run-time configuration settings described in Chapter 18. For example, if for some reason you want to disable index scans (hint: not a good idea) anytime you connect, you can use:

```
ALTER ROLE myname SET enable_indexscan TO off;
```

This will save the setting (but not set it immediately). In subsequent connections by this role it will appear as though `SET enable_indexscan TO off;` had been executed just before the session started. You can still alter this setting during the session; it will only be the default. To remove a role-specific default setting, use `ALTER ROLE rolename RESET varname;`. Note that role-specific defaults attached to roles without `LOGIN` privilege are fairly useless, since they will never be invoked.

## 19.3. Privileges

When an object is created, it is assigned an owner. The owner is normally the role that executed the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, *privileges* must be granted. There are several different kinds of privilege: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REFERENCES`, `TRIGGER`, `CREATE`, `CONNECT`, `TEMPORARY`, `EXECUTE`, and `USAGE`. For more information on the different types of privileges supported by PostgreSQL, see the *GRANT* reference page.

To assign privileges, the `GRANT` command is used. So, if `joe` is an existing role, and `accounts` is an existing table, the privilege to update the table can be granted with:

```
GRANT UPDATE ON accounts TO joe;
```

The special name `PUBLIC` can be used to grant a privilege to every role on the system. Writing `ALL` in place of a specific privilege specifies that all privileges that apply to the object will be granted.

To revoke a privilege, use the fittingly named *REVOKE* command:

```
REVOKE ALL ON accounts FROM PUBLIC;
```

The special privileges of an object's owner (i.e., the right to modify or destroy the object) are always implicit in being the owner, and cannot be granted or revoked. But the owner can choose to revoke his own ordinary privileges, for example to make a table read-only for himself as well as others.

An object can be assigned to a new owner with an `ALTER` command of the appropriate kind for the object. Superusers can always do this; ordinary roles can only do it if they are both the current owner of the object (or a member of the owning role) and a member of the new owning role.

## 19.4. Role Membership

It is frequently convenient to group users together to ease management of privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In PostgreSQL this is done by creating a role that represents the group, and then granting *membership* in the group role to individual user roles.

To set up a group role, first create the role:

```
CREATE ROLE name;
```

Typically a role being used as a group would not have the `LOGIN` attribute, though you can set it if you wish.

Once the group role exists, you can add and remove members using the `GRANT` and `REVOKE` commands:

```
GRANT group_role TO role1, ... ;
REVOKE group_role FROM role1, ... ;
```

You can grant membership to other group roles, too (since there isn't really any distinction between group roles and non-group roles). The database will not let you set up circular membership loops. Also, it is not permitted to grant membership in a role to `PUBLIC`.

The members of a role can use the privileges of the group role in two ways. First, every member of a group can explicitly do `SET ROLE` to temporarily “become” the group role. In this state, the database session has access to the privileges of the group role rather than the original login role, and any database objects created are considered owned by the group role not the login role. Second, member roles that have the `INHERIT` attribute automatically have use of privileges of roles they are members of. As an example, suppose we have done:

```
CREATE ROLE joe LOGIN INHERIT;
CREATE ROLE admin NOINHERIT;
CREATE ROLE wheel NOINHERIT;
GRANT admin TO joe;
GRANT wheel TO admin;
```

Immediately after connecting as role `joe`, a database session will have use of privileges granted directly to `joe` plus any privileges granted to `admin`, because `joe` “inherits” `admin`'s privileges. However, privileges granted to `wheel` are not available, because even though `joe` is indirectly a member of `wheel`, the membership is via `admin` which has the `NOINHERIT` attribute. After:

```
SET ROLE admin;
```

the session would have use of only those privileges granted to `admin`, and not those granted to `joe`. After:

```
SET ROLE wheel;
```

the session would have use of only those privileges granted to `wheel`, and not those granted to either `joe` or `admin`. The original privilege state can be restored with any of:

```
SET ROLE joe;
SET ROLE NONE;
RESET ROLE;
```

**Note:** The `SET ROLE` command always allows selecting any role that the original login role is directly or indirectly a member of. Thus, in the above example, it is not necessary to become `admin` before becoming `wheel`.

**Note:** In the SQL standard, there is a clear distinction between users and roles, and users do not automatically inherit privileges while roles do. This behavior can be obtained in PostgreSQL by giving roles being used as SQL roles the `INHERIT` attribute, while giving roles being used as SQL users the `NOINHERIT` attribute. However, PostgreSQL defaults to giving all roles the `INHERIT` attribute, for backwards compatibility with pre-8.1 releases in which users always had use of permissions granted to groups they were members of.

The role attributes `LOGIN`, `SUPERUSER`, `CREATEDB`, and `CREATEROLE` can be thought of as special privileges, but they are never inherited as ordinary privileges on database objects are. You must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. Continuing the above example, we might well choose to grant `CREATEDB` and `CREATEROLE` to the `admin` role. Then a session connecting as role `joe` would not have these privileges immediately, only after doing `SET ROLE admin`.

To destroy a group role, use *`DROP ROLE`*:

```
DROP ROLE name;
```

Any memberships in the group role are automatically revoked (but the member roles are not otherwise affected). Note however that any objects owned by the group role must first be dropped or reassigned to other owners; and any permissions granted to the group role must be revoked.

## 19.5. Functions and Triggers

Functions and triggers allow users to insert code into the backend server that other users might execute unintentionally. Hence, both mechanisms permit users to “Trojan horse” others with relative ease. The only real protection is tight control over who can define functions.

Functions run inside the backend server process with the operating system permissions of the database server daemon. If the programming language used for the function allows unchecked memory accesses, it is possible to change the server’s internal data structures. Hence, among many other things, such functions

can circumvent any system access controls. Function languages that allow such access are considered “untrusted”, and PostgreSQL allows only superusers to create functions written in those languages.

# Chapter 20. Managing Databases

Every instance of a running PostgreSQL server manages one or more databases. Databases are therefore the topmost hierarchical level for organizing SQL objects (“database objects”). This chapter describes the properties of databases, and how to create, manage, and destroy them.

## 20.1. Overview

A database is a named collection of SQL objects (“database objects”). Generally, every database object (tables, functions, etc.) belongs to one and only one database. (But there are a few system catalogs, for example `pg_database`, that belong to a whole cluster and are accessible from each database within the cluster.) More accurately, a database is a collection of schemas and the schemas contain the tables, functions, etc. So the full hierarchy is: server, database, schema, table (or some other kind of object, such as a function).

When connecting to the database server, a client must specify in its connection request the name of the database it wants to connect to. It is not possible to access more than one database per connection. (But an application is not restricted in the number of connections it opens to the same or other databases.) Databases are physically separated and access control is managed at the connection level. If one PostgreSQL server instance is to house projects or users that should be separate and for the most part unaware of each other, it is therefore recommendable to put them into separate databases. If the projects or users are interrelated and should be able to use each other’s resources they should be put in the same database, but possibly into separate schemas. Schemas are a purely logical structure and who can access what is managed by the privilege system. More information about managing schemas is in Section 5.7.

Databases are created with the `CREATE DATABASE` command (see Section 20.2) and destroyed with the `DROP DATABASE` command (see Section 20.5). To determine the set of existing databases, examine the `pg_database` system catalog, for example

```
SELECT datname FROM pg_database;
```

The `psql` program’s `\l` meta-command and `-l` command-line option are also useful for listing the existing databases.

**Note:** The SQL standard calls databases “catalogs”, but there is no difference in practice.

## 20.2. Creating a Database

In order to create a database, the PostgreSQL server must be up and running (see Section 17.3).

Databases are created with the SQL command `CREATE DATABASE`:

```
CREATE DATABASE name;
```

where *name* follows the usual rules for SQL identifiers. The current role automatically becomes the owner of the new database. It is the privilege of the owner of a database to remove it later on (which also removes all the objects in it, even if they have a different owner).

The creation of databases is a restricted operation. See Section 19.2 for how to grant permission.

Since you need to be connected to the database server in order to execute the `CREATE DATABASE` command, the question remains how the *first* database at any given site can be created. The first database is always created by the `initdb` command when the data storage area is initialized. (See Section 17.2.) This database is called `postgres`. So to create the first “ordinary” database you can connect to `postgres`.

A second database, `template1`, is also created by `initdb`. Whenever a new database is created within the cluster, `template1` is essentially cloned. This means that any changes you make in `template1` are propagated to all subsequently created databases. Therefore it is unwise to use `template1` for real work, but when used judiciously this feature can be convenient. More details appear in Section 20.3.

As a convenience, there is a program that you can execute from the shell to create new databases, `createdb`.

```
createdb dbname
```

`createdb` does no magic. It connects to the `postgres` database and issues the `CREATE DATABASE` command, exactly as described above. The `createdb` reference page contains the invocation details. Note that `createdb` without any arguments will create a database with the current user name, which might or might not be what you want.

**Note:** Chapter 21 contains information about how to restrict who can connect to a given database.

Sometimes you want to create a database for someone else. That role should become the owner of the new database, so he can configure and manage it himself. To achieve that, use one of the following commands:

```
CREATE DATABASE dbname OWNER rolename;
```

from the SQL environment, or:

```
createdb -O rolename dbname
```

from the shell. You must be a superuser to be allowed to create a database for someone else (that is, for a role you are not a member of).

## 20.3. Template Databases

`CREATE DATABASE` actually works by copying an existing database. By default, it copies the standard system database named `template1`. Thus that database is the “template” from which new databases are made. If you add objects to `template1`, these objects will be copied into subsequently created user databases. This behavior allows site-local modifications to the standard set of objects in databases. For example, if you install the procedural language PL/pgSQL in `template1`, it will automatically be available in user databases without any extra action being taken when those databases are made.

There is a second standard system database named `template0`. This database contains the same data as the initial contents of `template1`, that is, only the standard objects predefined by your version of PostgreSQL. `template0` should never be changed after `initdb`. By instructing `CREATE DATABASE` to copy `template0` instead of `template1`, you can create a “virgin” user database that contains none of the site-local additions in `template1`. This is particularly handy when restoring a `pg_dump` dump: the dump script should be restored in a virgin database to ensure that one recreates the correct contents of the dumped database, without any conflicts with additions that can now be present in `template1`.

To create a database by copying `template0`, use:

```
CREATE DATABASE dbname TEMPLATE template0;
```

from the SQL environment, or:

```
createdb -T template0 dbname
```

from the shell.

It is possible to create additional template databases, and indeed one can copy any database in a cluster by specifying its name as the template for `CREATE DATABASE`. It is important to understand, however, that this is not (yet) intended as a general-purpose “COPY DATABASE” facility. The principal limitation is that no other sessions can be connected to the source database while it is being copied. `CREATE DATABASE` will fail if any other connection exists when it starts; otherwise, new connections to the source database are locked out until `CREATE DATABASE` completes.

Two useful flags exist in `pg_database` for each database: the columns `datistemplate` and `dataallowconn`. `datistemplate` can be set to indicate that a database is intended as a template for `CREATE DATABASE`. If this flag is set, the database can be cloned by any user with `CREATEDB` privileges; if it is not set, only superusers and the owner of the database can clone it. If `dataallowconn` is false, then no new connections to that database will be allowed (but existing sessions are not killed simply by setting the flag false). The `template0` database is normally marked `dataallowconn = false` to prevent modification of it. Both `template0` and `template1` should always be marked with `datistemplate = true`.

**Note:** `template1` and `template0` do not have any special status beyond the fact that the name `template1` is the default source database name for `CREATE DATABASE`. For example, one could drop `template1` and recreate it from `template0` without any ill effects. This course of action might be advisable if one has carelessly added a bunch of junk in `template1`. (To delete `template1`, it must have `pg_database.datistemplate = false`.)

The `postgres` database is also created when a database cluster is initialized. This database is meant as a default database for users and applications to connect to. It is simply a copy of `template1` and can be dropped and recreated if required.

## 20.4. Database Configuration

Recall from Chapter 18 that the PostgreSQL server provides a large number of run-time configuration variables. You can set database-specific default values for many of these settings.

For example, if for some reason you want to disable the GEQO optimizer for a given database, you'd ordinarily have to either disable it for all databases or make sure that every connecting client is careful to issue `SET geqo TO off;`. To make this setting the default within a particular database, you can execute the command:

```
ALTER DATABASE mydb SET geqo TO off;
```

This will save the setting (but not set it immediately). In subsequent connections to this database it will appear as though `SET geqo TO off;` had been executed just before the session started. Note that users can still alter this setting during their sessions; it will only be the default. To undo any such setting, use `ALTER DATABASE dbname RESET varname;`.

## 20.5. Destroying a Database

Databases are destroyed with the command *DROP DATABASE*:

```
DROP DATABASE name;
```

Only the owner of the database, or a superuser, can drop a database. Dropping a database removes all objects that were contained within the database. The destruction of a database cannot be undone.

You cannot execute the `DROP DATABASE` command while connected to the victim database. You can, however, be connected to any other database, including the `template1` database. `template1` would be the only option for dropping the last user database of a given cluster.

For convenience, there is also a shell program to drop databases, `dropdb`:

```
dropdb dbname
```

(Unlike `createdb`, it is not the default action to drop the database with the current user name.)

## 20.6. Tablespaces

Tablespaces in PostgreSQL allow database administrators to define locations in the file system where the files representing database objects can be stored. Once created, a tablespace can be referred to by name when creating database objects.

By using tablespaces, an administrator can control the disk layout of a PostgreSQL installation. This is useful in at least two ways. First, if the partition or volume on which the cluster was initialized runs out of space and cannot be extended, a tablespace can be created on a different partition and used until the system can be reconfigured.

Second, tablespaces allow an administrator to use knowledge of the usage pattern of database objects to optimize performance. For example, an index which is very heavily used can be placed on a very fast, highly available disk, such as an expensive solid state device. At the same time a table storing archived data which is rarely used or not performance critical could be stored on a less expensive, slower disk system.

To define a tablespace, use the *CREATE TABLESPACE* command, for example::

```
CREATE TABLESPACE fastspace LOCATION '/mnt/sdal/postgresql/data';
```

The location must be an existing, empty directory that is owned by the PostgreSQL system user. All objects subsequently created within the tablespace will be stored in files underneath this directory.

**Note:** There is usually not much point in making more than one tablespace per logical file system, since you cannot control the location of individual files within a logical file system. However, PostgreSQL does not enforce any such limitation, and indeed it is not directly aware of the file system boundaries on your system. It just stores files in the directories you tell it to use.

Creation of the tablespace itself must be done as a database superuser, but after that you can allow ordinary database users to make use of it. To do that, grant them the `CREATE` privilege on it.

Tables, indexes, and entire databases can be assigned to particular tablespaces. To do so, a user with the `CREATE` privilege on a given tablespace must pass the tablespace name as a parameter to the relevant command. For example, the following creates a table in the tablespace `spacel`:

```
CREATE TABLE foo(i int) TABLESPACE spacel;
```

Alternatively, use the `default_tablespace` parameter:

```
SET default_tablespace = spacel;
CREATE TABLE foo(i int);
```

When `default_tablespace` is set to anything but an empty string, it supplies an implicit `TABLESPACE` clause for `CREATE TABLE` and `CREATE INDEX` commands that do not have an explicit one.

There is also a `temp_tablespaces` parameter, which determines the placement of temporary tables and indexes, as well as temporary files that are used for purposes such as sorting large data sets. This can be a list of tablespace names, rather than only one, so that the load associated with temporary objects can be spread over multiple tablespaces. A random member of the list is picked each time a temporary object is to be created.

The tablespace associated with a database is used to store the system catalogs of that database. Furthermore, it is the default tablespace used for tables, indexes, and temporary files created within the database, if no `TABLESPACE` clause is given and no other selection is specified by `default_tablespace` or `temp_tablespaces` (as appropriate). If a database is created without specifying a tablespace for it, it uses the same tablespace as the template database it is copied from.

Two tablespaces are automatically created by `initdb`. The `pg_global` tablespace is used for shared system catalogs. The `pg_default` tablespace is the default tablespace of the `template1` and `template0` databases (and, therefore, will be the default tablespace for other databases as well, unless overridden by a `TABLESPACE` clause in `CREATE DATABASE`).

Once created, a tablespace can be used from any database, provided the requesting user has sufficient privilege. This means that a tablespace cannot be dropped until all objects in all databases using the tablespace have been removed.

To remove an empty tablespace, use the `DROP TABLESPACE` command.

To determine the set of existing tablespaces, examine the `pg_tablespace` system catalog, for example

```
SELECT spcname FROM pg_tablespace;
```

The `psql` program's `\db` meta-command is also useful for listing the existing tablespaces.

PostgreSQL makes use of symbolic links to simplify the implementation of tablespaces. This means that tablespaces can be used *only* on systems that support symbolic links.

The directory `$PGDATA/pg_tblspc` contains symbolic links that point to each of the non-built-in tablespaces defined in the cluster. Although not recommended, it is possible to adjust the tablespace layout by hand by redefining these links. Two warnings: do not do so while the server is running; and after you restart the server, update the `pg_tablespace` catalog to show the new locations. (If you do not, `pg_dump` will continue to show the old tablespace locations.)

# Chapter 21. Client Authentication

When a client application connects to the database server, it specifies which PostgreSQL database user name it wants to connect as, much the same way one logs into a Unix computer as a particular user. Within the SQL environment the active database user name determines access privileges to database objects — see Chapter 19 for more information. Therefore, it is essential to restrict which database users can connect.

**Note:** As explained in Chapter 19, PostgreSQL actually does privilege management in terms of “roles”. In this chapter, we consistently use *database user* to mean “role with the `LOGIN` privilege”.

*Authentication* is the process by which the database server establishes the identity of the client, and by extension determines whether the client application (or the user who runs the client application) is permitted to connect with the database user name that was requested.

PostgreSQL offers a number of different client authentication methods. The method used to authenticate a particular client connection can be selected on the basis of (client) host address, database, and user.

PostgreSQL database user names are logically separate from user names of the operating system in which the server runs. If all the users of a particular server also have accounts on the server’s machine, it makes sense to assign database user names that match their operating system user names. However, a server that accepts remote connections might have many database users who have no local operating system account, and in such cases there need be no connection between database user names and OS user names.

## 21.1. The `pg_hba.conf` file

Client authentication is controlled by a configuration file, which traditionally is named `pg_hba.conf` and is stored in the database cluster’s data directory. (HBA stands for host-based authentication.) A default `pg_hba.conf` file is installed when the data directory is initialized by `initdb`. It is possible to place the authentication configuration file elsewhere, however; see the `hba_file` configuration parameter.

The general format of the `pg_hba.conf` file is a set of records, one per line. Blank lines are ignored, as is any text after the `#` comment character. A record is made up of a number of fields which are separated by spaces and/or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines.

Each record specifies a connection type, a client IP address range (if relevant for the connection type), a database name, a user name, and the authentication method to be used for connections matching these parameters. The first record with a matching connection type, client address, requested database, and user name is used to perform authentication. There is no “fall-through” or “backup”: if one record is chosen and the authentication fails, subsequent records are not considered. If no record matches, access is denied.

A record can have one of the seven formats

<code>local</code>	<code>database</code>	<code>user</code>	<code>auth-method</code>	<code>[auth-option]</code>	
<code>host</code>	<code>database</code>	<code>user</code>	<code>CIDR-address</code>	<code>auth-method</code>	<code>[auth-option]</code>
<code>hostssl</code>	<code>database</code>	<code>user</code>	<code>CIDR-address</code>	<code>auth-method</code>	<code>[auth-option]</code>
<code>hostnossl</code>	<code>database</code>	<code>user</code>	<code>CIDR-address</code>	<code>auth-method</code>	<code>[auth-option]</code>
<code>host</code>	<code>database</code>	<code>user</code>	<code>IP-address</code>	<code>IP-mask</code>	<code>auth-method [auth-option]</code>
<code>hostssl</code>	<code>database</code>	<code>user</code>	<code>IP-address</code>	<code>IP-mask</code>	<code>auth-method [auth-option]</code>

```
hostnossl database user IP-address IP-mask auth-method [auth-option]
```

The meaning of the fields is as follows:

`local`

This record matches connection attempts using Unix-domain sockets. Without a record of this type, Unix-domain socket connections are disallowed.

`host`

This record matches connection attempts made using TCP/IP. `host` records match either SSL or non-SSL connection attempts.

**Note:** Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the `listen_addresses` configuration parameter, since the default behavior is to listen for TCP/IP connections only on the local loopback address `localhost`.

`hostssl`

This record matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption.

To make use of this option the server must be built with SSL support. Furthermore, SSL must be enabled at server start time by setting the `ssl` configuration parameter (see Section 17.8 for more information).

`hostnossl`

This record type has the opposite logic to `hostssl`: it only matches connection attempts made over TCP/IP that do not use SSL.

`database`

Specifies which database names this record matches. The value `all` specifies that it matches all databases. The value `sameuser` specifies that the record matches if the requested database has the same name as the requested user. The value `samerole` specifies that the requested user must be a member of the role with the same name as the requested database. (`samegroup` is an obsolete but still accepted spelling of `samerole`.) Otherwise, this is the name of a specific PostgreSQL database. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with `@`.

`user`

Specifies which database user names this record matches. The value `all` specifies that it matches all users. Otherwise, this is either the name of a specific database user, or a group name preceded by `+`. (Recall that there is no real distinction between users and groups in PostgreSQL; a `+` mark really means “match any of the roles that are directly or indirectly members of this role”, while a name without a `+` mark matches only that specific role.) Multiple user names can be supplied by separating them with commas. A separate file containing user names can be specified by preceding the file name with `@`.

*CIDR-address*

Specifies the client machine IP address range that this record matches. It contains an IP address in standard dotted decimal notation and a CIDR mask length. (IP addresses can only be specified numerically, not as domain or host names.) The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this must be zero in the given IP address. There must not be any white space between the IP address, the /, and the CIDR mask length.

Typical examples of a *CIDR-address* are `172.20.143.89/32` for a single host, or `172.20.143.0/24` for a small network, or `10.6.0.0/16` for a larger one. To specify a single host, use a CIDR mask of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.

An IP address given in IPv4 format will match IPv6 connections that have the corresponding address, for example `127.0.0.1` will match the IPv6 address `::ffff:127.0.0.1`. An entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range. Note that entries in IPv6 format will be rejected if the system's C library does not have support for IPv6 addresses.

This field only applies to `host`, `hostssl`, and `hostnossl` records.

*IP-address**IP-mask*

These fields can be used as an alternative to the *CIDR-address* notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, `255.0.0.0` represents an IPv4 CIDR mask length of 8, and `255.255.255.255` represents a CIDR mask length of 32.

These fields only apply to `host`, `hostssl`, and `hostnossl` records.

*auth-method*

Specifies the authentication method to use when connecting via this record. The possible choices are summarized here; details are in Section 21.2.

*trust*

Allow the connection unconditionally. This method allows anyone that can connect to the PostgreSQL database server to login as any PostgreSQL user they like, without the need for a password. See Section 21.2.1 for details.

*reject*

Reject the connection unconditionally. This is useful for “filtering out” certain hosts from a group.

*md5*

Require the client to supply an MD5-encrypted password for authentication. See Section 21.2.2 for details.

*crypt*

**Note:** This option is recommended only for communicating with pre-7.2 clients.

Require the client to supply a `crypt()`-encrypted password for authentication. `md5` is now recommended over `crypt`. See Section 21.2.2 for details.

`password`

Require the client to supply an unencrypted password for authentication. Since the password is sent in clear text over the network, this should not be used on untrusted networks. It also does not usually work with threaded client applications. See Section 21.2.2 for details.

`gss`

Use GSSAPI to authenticate the user. This is only available for TCP/IP connections. See Section 21.2.3 for details.

`sspi`

Use SSPI to authenticate the user. This is only available on Windows. See Section 21.2.4 for details.

`krb5`

Use Kerberos V5 to authenticate the user. This is only available for TCP/IP connections. See Section 21.2.5 for details.

`ident`

Obtain the operating system user name of the client (for TCP/IP connections by contacting the ident server on the client, for local connections by getting it from the operating system) and check if the user is allowed to connect as the requested database user by consulting the map specified after the `ident` key word. See Section 21.2.6 for details.

`ldap`

Authenticate using LDAP to a central server. See Section 21.2.7 for details.

`pam`

Authenticate using the Pluggable Authentication Modules (PAM) service provided by the operating system. See Section 21.2.8 for details.

`auth-option`

The meaning of this optional field depends on the chosen authentication method. Details appear below.

Files included by `@` constructs are read as lists of names, which can be separated by either whitespace or commas. Comments are introduced by `#`, just as in `pg_hba.conf`, and nested `@` constructs are allowed. Unless the file name following `@` is an absolute path, it is taken to be relative to the directory containing the referencing file.

Since the `pg_hba.conf` records are examined sequentially for each connection attempt, the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example, one might wish to use `trust` authentication for local TCP/IP connections but require a password for remote TCP/IP connections. In this case a record specifying `trust` authentication for connections from 127.0.0.1 would appear before a record specifying password authentication for a wider range of allowed client IP addresses.

The `pg_hba.conf` file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you will need to signal the server (using `pg_ctl reload` or `kill -HUP`) to make it re-read the file.

**Tip:** To connect to a particular database, a user must not only pass the `pg_hba.conf` checks, but must have the `CONNECT` privilege for the database. If you wish to restrict which users can connect to which databases, it's usually easier to control this by granting/revoking `CONNECT` privilege than to put the rules into `pg_hba.conf` entries.

Some examples of `pg_hba.conf` entries are shown in Example 21-1. See the next section for details on the different authentication methods.

### Example 21-1. Example `pg_hba.conf` entries

```
# Allow any user on the local system to connect to any database under
# any database user name using Unix-domain sockets (the default for local
# connections).
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
local  all      all           trust

# The same using local loopback TCP/IP connections.
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
host    all      all     127.0.0.1/32   trust

# The same as the last line but using a separate netmask column
#
# TYPE  DATABASE  USER  IP-ADDRESS  IP-MASK  METHOD
host    all      all     127.0.0.1    255.255.255.255  trust

# Allow any user from any host with IP address 192.168.93.x to connect
# to database "postgres" as the same user name that ident reports for
# the connection (typically the Unix user name).
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
host    postgres  all     192.168.93.0/24  ident sameuser

# Allow a user from host 192.168.12.10 to connect to database
# "postgres" if the user's password is correctly supplied.
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
host    postgres  all     192.168.12.10/32  md5

# In the absence of preceding "host" lines, these two lines will
# reject all connection from 192.168.54.1 (since that entry will be
# matched first), but allow Kerberos 5 connections from anywhere else
# on the Internet. The zero mask means that no bits of the host IP
# address are considered so it matches any host.
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
```

```

host      all            all            192.168.54.1/32      reject
host      all            all            0.0.0.0/0            krb5

# Allow users from 192.168.x.x hosts to connect to any database, if
# they pass the ident check.  If, for example, ident says the user is
# "bryanh" and he requests to connect as PostgreSQL user "guest1", the
# connection is allowed if there is an entry in pg_ident.conf for map
# "omicron" that says "bryanh" is allowed to connect as "guest1".
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
host    all      all    192.168.0.0/16  ident omicron

# If these are the only three lines for local connections, they will
# allow local users to connect only to their own databases (databases
# with the same name as their database user name) except for administrators
# and members of role "support", who can connect to all databases.  The file
# $PGDATA/admins contains a list of names of administrators.  Passwords
# are required in all cases.
#
# TYPE  DATABASE  USER  CIDR-ADDRESS  METHOD
local   sameuser  all    all           md5
local   all      @admins    md5
local   all      +support   md5

# The last two lines above can be combined into a single line:
local   all      @admins,+support   md5

# The database column can also use lists and file names:
local   db1,db2,@demodbs  all    md5

```

## 21.2. Authentication methods

The following subsections describe the authentication methods in more detail.

### 21.2.1. Trust authentication

When `trust` authentication is specified, PostgreSQL assumes that anyone who can connect to the server is authorized to access the database with whatever database user name they specify (including superusers). Of course, restrictions made in the `database` and `user` columns still apply. This method should only be used when there is adequate operating-system-level protection on connections to the server.

`trust` authentication is appropriate and very convenient for local connections on a single-user workstation. It is usually *not* appropriate by itself on a multiuser machine. However, you might be able to use `trust` even on a multiuser machine, if you restrict access to the server's Unix-domain socket file using file-system permissions. To do this, set the `unix_socket_permissions` (and possibly `unix_socket_group`) configuration parameters as described in Section 18.3. Or you could set the `unix_socket_directory` configuration parameter to place the socket file in a suitably restricted directory.

Setting file-system permissions only helps for Unix-socket connections. Local TCP/IP connections are not restricted by it; therefore, if you want to use file-system permissions for local security, remove the `host ... 127.0.0.1 ...` line from `pg_hba.conf`, or change it to a non-`trust` authentication method.

`trust` authentication is only suitable for TCP/IP connections if you trust every user on every machine that is allowed to connect to the server by the `pg_hba.conf` lines that specify `trust`. It is seldom reasonable to use `trust` for any TCP/IP connections other than those from localhost (127.0.0.1).

### 21.2.2. Password authentication

The password-based authentication methods are `md5`, `crypt`, and `password`. These methods operate similarly except for the way that the password is sent across the connection: respectively, MD5-hashed, crypt-encrypted, and clear-text. A limitation is that the `crypt` method does not work with passwords that have been encrypted in `pg_authid`.

If you are at all concerned about password “sniffing” attacks then `md5` is preferred, with `crypt` to be used only if you must support pre-7.2 clients. Plain `password` should be avoided especially for connections over the open Internet (unless you use SSL, SSH, or another communications security wrapper around the connection).

PostgreSQL database passwords are separate from operating system user passwords. The password for each database user is stored in the `pg_authid` system catalog. Passwords can be managed with the SQL commands `CREATE USER` and `ALTER USER`, e.g., `CREATE USER foo WITH PASSWORD 'secret';`. By default, that is, if no password has been set up, the stored password is null and password authentication will always fail for that user.

### 21.2.3. GSSAPI authentication

GSSAPI is an industry-standard protocol for secure authentication defined in RFC 2743. PostgreSQL supports GSSAPI with Kerberos authentication according to RFC 1964. GSSAPI provides automatic authentication (single sign-on) for systems that support it. The authentication itself is secure, but the data sent over the connection will be in clear unless SSL is used.

When GSSAPI uses Kerberos, it uses a standard principal in format `servicename/hostname@realm`. For information about the parts of the principal, and how to set up the required keys, see Section 21.2.5. GSSAPI support has to be enabled when PostgreSQL is built; see Chapter 15 for more information.

### 21.2.4. SSPI authentication

SSPI is a Windows technology for secure authentication with single sign-on. PostgreSQL will use SSPI in `negotiate` mode, which will use Kerberos when possible and automatically fall back to NTLM in other cases. SSPI authentication only works when both server and client are running Windows.

When using Kerberos authentication, SSPI works the same way GSSAPI does. See Section 21.2.3 for details.

## 21.2.5. Kerberos authentication

**Note:** Native Kerberos authentication has been deprecated and should be used only for backward compatibility. New and upgraded installations are encouraged to use the industry-standard GSSAPI authentication (see Section 21.2.3) instead.

Kerberos is an industry-standard secure authentication system suitable for distributed computing over a public network. A description of the Kerberos system is far beyond the scope of this document; in full generality it can be quite complex (yet powerful). The Kerberos FAQ<sup>1</sup> or MIT Kerberos page<sup>2</sup> can be good starting points for exploration. Several sources for Kerberos distributions exist. Kerberos provides secure authentication but does not encrypt queries or data passed over the network; for that use SSL.

PostgreSQL supports Kerberos version 5. Kerberos support has to be enabled when PostgreSQL is built; see Chapter 15 for more information.

PostgreSQL operates like a normal Kerberos service. The name of the service principal is *servicename/hostname@realm*.

*servicename* can be set on the server side using the *krb\_srvname* configuration parameter, and on the client side using the *krbsrvname* connection parameter. (See also Section 30.1.) The installation default can be changed from the default *postgres* at build time using *./configure --with-krb-srvnam=whatever*. In most environments, this parameter never needs to be changed. However, to support multiple PostgreSQL installations on the same host it is necessary. Some Kerberos implementations might also require a different service name, such as Microsoft Active Directory which requires the service name to be in uppercase (*POSTGRES*).

*hostname* is the fully qualified host name of the server machine. The service principal's realm is the preferred realm of the server machine.

Client principals must have their PostgreSQL database user name as their first component, for example *pgusername@realm*. By default, the realm of the client is not checked by PostgreSQL. If you have cross-realm authentication enabled and need to verify the realm, use the *krb\_realm* parameter.

Make sure that your server keytab file is readable (and preferably only readable) by the PostgreSQL server account. (See also Section 17.1.) The location of the key file is specified by the *krb\_server\_keyfile* configuration parameter. The default is */usr/local/pgsql/etc/krb5.keytab* (or whichever directory was specified as *sysconfdir* at build time).

The keytab file is generated by the Kerberos software; see the Kerberos documentation for details. The following example is for MIT-compatible Kerberos 5 implementations:

```
kadmin% ank -randkey postgres/server.my.domain.org
kadmin% ktadd -k krb5.keytab postgres/server.my.domain.org
```

When connecting to the database make sure you have a ticket for a principal matching the requested database user name. For example, for database user name *fred*, both principal *fred@EXAMPLE.COM* and *fred/users.example.com@EXAMPLE.COM* could be used to authenticate to the database server.

1. <http://www.nrl.navy.mil/CCS/people/kenh/kerberos-faq.html>
2. <http://web.mit.edu/kerberos/www/>

If you use `mod_auth_kerb`<sup>3</sup> and `mod_perl` on your Apache web server, you can use `AuthType KerberosV5SaveCredentials` with a `mod_perl` script. This gives secure database access over the web, no extra passwords required.

## 21.2.6. Ident-based authentication

The ident authentication method works by obtaining the client's operating system user name, then determining the allowed database user names using a map file that lists the permitted corresponding pairs of names. The determination of the client's user name is the security-critical point, and it works differently depending on the connection type.

### 21.2.6.1. Ident Authentication over TCP/IP

The "Identification Protocol" is described in RFC 1413. Virtually every Unix-like operating system ships with an ident server that listens on TCP port 113 by default. The basic functionality of an ident server is to answer questions like "What user initiated the connection that goes out of your port *x* and connects to my port *y*?". Since PostgreSQL knows both *x* and *y* when a physical connection is established, it can interrogate the ident server on the host of the connecting client and could theoretically determine the operating system user for any given connection this way.

The drawback of this procedure is that it depends on the integrity of the client: if the client machine is untrusted or compromised an attacker could run just about any program on port 113 and return any user name he chooses. This authentication method is therefore only appropriate for closed networks where each client machine is under tight control and where the database and system administrators operate in close contact. In other words, you must trust the machine running the ident server. Heed the warning:

The Identification Protocol is not intended as an authorization or access control protocol.

—RFC 1413

Some ident servers have a nonstandard option that causes the returned user name to be encrypted, using a key that only the originating machine's administrator knows. This option *must not* be used when using the ident server with PostgreSQL, since PostgreSQL does not have any way to decrypt the returned string to determine the actual user name.

### 21.2.6.2. Ident Authentication over Local Sockets

On systems supporting `SO_PEERCRECRED` requests for Unix-domain sockets (currently Linux, FreeBSD, NetBSD, OpenBSD, and BSD/OS), ident authentication can also be applied to local connections. In this case, no security risk is added by using ident authentication; indeed it is a preferable choice for local connections on such systems.

On systems without `SO_PEERCRECRED` requests, ident authentication is only available for TCP/IP connections. As a work-around, it is possible to specify the localhost address 127.0.0.1 and make connections to this address. This method is trustworthy to the extent that you trust the local ident server.

---

3. <http://modauthkerb.sf.net>

### 21.2.6.3. Ident Maps

When using ident-based authentication, after having determined the name of the operating system user that initiated the connection, PostgreSQL checks whether that user is allowed to connect as the database user he is requesting to connect as. This is controlled by the ident map argument that follows the `ident` key word in the `pg_hba.conf` file. There is a predefined ident map `sameuser`, which allows any operating system user to connect as the database user of the same name (if the latter exists). Other maps must be created manually.

Ident maps other than `sameuser` are defined in the ident map file, which by default is named `pg_ident.conf` and is stored in the cluster's data directory. (It is possible to place the map file elsewhere, however; see the `ident_file` configuration parameter.) The ident map file contains lines of the general form:

```
map-name ident-username database-username
```

Comments and whitespace are handled in the same way as in `pg_hba.conf`. The `map-name` is an arbitrary name that will be used to refer to this mapping in `pg_hba.conf`. The other two fields specify which operating system user is allowed to connect as which database user. The same `map-name` can be used repeatedly to specify more user-mappings within a single map. There is no restriction regarding how many database users a given operating system user can correspond to, nor vice versa.

The `pg_ident.conf` file is read on start-up and when the main server process receives a SIGHUP signal. If you edit the file on an active system, you will need to signal the server (using `pg_ctl reload` or `kill -HUP`) to make it re-read the file.

A `pg_ident.conf` file that could be used in conjunction with the `pg_hba.conf` file in Example 21-1 is shown in Example 21-2. In this example setup, anyone logged in to a machine on the 192.168 network that does not have the Unix user name `bryanh`, `ann`, or `robert` would not be granted access. Unix user `robert` would only be allowed access when he tries to connect as PostgreSQL user `bob`, not as `robert` or anyone else. `ann` would only be allowed to connect as `ann`. User `bryanh` would be allowed to connect as either `bryanh` himself or as `guest1`.

#### Example 21-2. An example `pg_ident.conf` file

```
# MAPNAME          IDENT-USERNAME      PG-USERNAME

omicron            bryanh              bryanh
omicron            ann                ann
# bob has user name robert on these machines
omicron            robert             bob
# bryanh can also connect as guest1
omicron            bryanh              guest1
```

### 21.2.7. LDAP authentication

This authentication method operates similarly to `password` except that it uses LDAP as the authentication method. LDAP is used only to validate the user name/password pairs. Therefore the user must already exist

in the database before LDAP can be used for authentication. The server and parameters used are specified after the `ldap` key word in the file `pg_hba.conf`. The format of this parameter is:

```
ldap[s]://servername[:port]/base dn[:prefix[:suffix]]
```

Commas are used to specify multiple items in an `ldap` component. However, because unquoted commas are treated as item separators in `pg_hba.conf`, it is wise to double-quote the `ldap` URL to preserve any commas present, e.g.:

```
"ldap://ldap.example.net/dc=example,dc=net;EXAMPLE\"
```

If `ldaps` is specified instead of `ldap`, TLS encryption will be enabled for the connection. Note that this will encrypt only the connection between the PostgreSQL server and the LDAP server. The connection between the client and the PostgreSQL server is not affected by this setting. To make use of TLS encryption, you might need to configure the LDAP library prior to configuring PostgreSQL. Note that encrypted LDAP is available only if the platform's LDAP library supports it.

If no port is specified, the default port as configured in the LDAP library will be used.

The server will bind to the distinguished name specified as `base dn` using the user name supplied by the client. If `prefix` and `suffix` is specified, it will be prepended and appended to the user name before the bind. Typically, the prefix parameter is used to specify `cn=`, or `DOMAIN\` in an Active Directory environment.

## 21.2.8. PAM authentication

This authentication method operates similarly to `password` except that it uses PAM (Pluggable Authentication Modules) as the authentication mechanism. The default PAM service name is `postgresql`. You can optionally supply your own service name after the `pam` key word in the file `pg_hba.conf`. PAM is used only to validate user name/password pairs. Therefore the user must already exist in the database before PAM can be used for authentication. For more information about PAM, please read the [Linux-PAM Page](http://www.kernel.org/pub/linux/libs/pam/)<sup>4</sup> and the [Solaris PAM Page](http://www.sun.com/software/solaris/pam/)<sup>5</sup>.

**Note:** If PAM is set up to read `/etc/shadow`, authentication will fail because the PostgreSQL server is started by a non-root user. However, this is not an issue with LDAP or other authentication methods.

## 21.3. Authentication problems

Genuine authentication failures and related problems generally manifest themselves through error messages like the following.

4. <http://www.kernel.org/pub/linux/libs/pam/>

5. <http://www.sun.com/software/solaris/pam/>

```
FATAL: no pg_hba.conf entry for host "123.123.123.123", user "andym", database "testdb"
```

This is what you are most likely to get if you succeed in contacting the server, but it does not want to talk to you. As the message suggests, the server refused the connection request because it found no matching entry in its `pg_hba.conf` configuration file.

```
FATAL: Password authentication failed for user "andym"
```

Messages like this indicate that you contacted the server, and it is willing to talk to you, but not until you pass the authorization method specified in the `pg_hba.conf` file. Check the password you are providing, or check your Kerberos or ident software if the complaint mentions one of those authentication types.

```
FATAL: user "andym" does not exist
```

The indicated user name was not found.

```
FATAL: database "testdb" does not exist
```

The database you are trying to connect to does not exist. Note that if you do not specify a database name, it defaults to the database user name, which might or might not be the right thing.

**Tip:** The server log might contain more information about an authentication failure than is reported to the client. If you are confused about the reason for a failure, check the log.

# Chapter 22. Localization

This chapter describes the available localization features from the point of view of the administrator. PostgreSQL supports localization with two approaches:

- Using the locale features of the operating system to provide locale-specific collation order, number formatting, translated messages, and other aspects.
- Providing a number of different character sets defined in the PostgreSQL server, including multiple-byte character sets, to support storing text in all kinds of languages, and providing character set translation between client and server.

## 22.1. Locale Support

*Locale* support refers to an application respecting cultural preferences regarding alphabets, sorting, number formatting, etc. PostgreSQL uses the standard ISO C and POSIX locale facilities provided by the server operating system. For additional information refer to the documentation of your system.

### 22.1.1. Overview

Locale support is automatically initialized when a database cluster is created using `initdb`. `initdb` will initialize the database cluster with the locale setting of its execution environment by default, so if your system is already set to use the locale that you want in your database cluster then there is nothing else you need to do. If you want to use a different locale (or you are not sure which locale your system is set to), you can instruct `initdb` exactly which locale to use by specifying the `--locale` option. For example:

```
initdb --locale=sv_SE
```

This example sets the locale to Swedish (`sv`) as spoken in Sweden (`SE`). Other possibilities might be `en_US` (U.S. English) and `fr_CA` (French Canadian). If more than one character set can be useful for a locale then the specifications look like this: `cs_CZ.ISO8859-2`. What locales are available under what names on your system depends on what was provided by the operating system vendor and what was installed. (On most systems, the command `locale -a` will provide a list of available locales.)

Occasionally it is useful to mix rules from several locales, e.g., use English collation rules but Spanish messages. To support that, a set of locale subcategories exist that control only a certain aspect of the localization rules:

LC_COLLATE	String sort order
LC_CTYPE	Character classification (What is a letter? Its upper-case equivalent?)
LC_MESSAGES	Language of messages

LC_MONETARY	Formatting of currency amounts
LC_NUMERIC	Formatting of numbers
LC_TIME	Formatting of dates and times

The category names translate into names of `initdb` options to override the locale choice for a specific category. For instance, to set the locale to French Canadian, but use U.S. rules for formatting currency, use `initdb --locale=fr_CA --lc-monetary=en_US`.

If you want the system to behave as if it had no locale support, use the special locale `C` or `POSIX`.

The nature of some locale categories is that their value has to be fixed for the lifetime of a database cluster. That is, once `initdb` has run, you cannot change them anymore. `LC_COLLATE` and `LC_CTYPE` are those categories. They affect the sort order of indexes, so they must be kept fixed, or indexes on text columns will become corrupt. PostgreSQL enforces this by recording the values of `LC_COLLATE` and `LC_CTYPE` that are seen by `initdb`. The server automatically adopts those two values when it is started.

The other locale categories can be changed as desired whenever the server is running by setting the run-time configuration variables that have the same name as the locale categories (see Section 18.10.2 for details). The defaults that are chosen by `initdb` are actually only written into the configuration file `postgresql.conf` to serve as defaults when the server is started. If you delete these assignments from `postgresql.conf` then the server will inherit the settings from its execution environment.

Note that the locale behavior of the server is determined by the environment variables seen by the server, not by the environment of any client. Therefore, be careful to configure the correct locale settings before starting the server. A consequence of this is that if client and server are set up in different locales, messages might appear in different languages depending on where they originated.

**Note:** When we speak of inheriting the locale from the execution environment, this means the following on most operating systems: For a given locale category, say the collation, the following environment variables are consulted in this order until one is found to be set: `LC_ALL`, `LC_COLLATE` (the variable corresponding to the respective category), `LANG`. If none of these environment variables are set then the locale defaults to `C`.

Some message localization libraries also look at the environment variable `LANGUAGE` which overrides all other locale settings for the purpose of setting the language of messages. If in doubt, please refer to the documentation of your operating system, in particular the documentation about `gettext`, for more information.

To enable messages to be translated to the user's preferred language, NLS must have been enabled at build time. This choice is independent of the other locale support.

## 22.1.2. Behavior

The locale settings influence the following SQL features:

- Sort order in queries using `ORDER BY` on textual data
- The ability to use indexes with `LIKE` clauses

- The `upper`, `lower`, and `initcap` functions
- The `to_char` family of functions

The drawback of using locales other than `C` or `POSIX` in PostgreSQL is its performance impact. It slows character handling and prevents ordinary indexes from being used by `LIKE`. For this reason use locales only if you actually need them.

As a workaround to allow PostgreSQL to use indexes with `LIKE` clauses under a non-`C` locale, several custom operator classes exist. These allow the creation of an index that performs a strict character-by-character comparison, ignoring locale comparison rules. Refer to Section 11.9 for more information.

### 22.1.3. Problems

If locale support doesn't work according to the explanation above, check that the locale support in your operating system is correctly configured. To check what locales are installed on your system, you can use the command `locale -a` if your operating system provides it.

Check that PostgreSQL is actually using the locale that you think it is. `LC_COLLATE` and `LC_CTYPE` settings are determined at `initdb` time and cannot be changed without repeating `initdb`. Other locale settings including `LC_MESSAGES` and `LC_MONETARY` are initially determined by the environment the server is started in, but can be changed on-the-fly. You can check the active locale settings using the `SHOW` command.

The directory `src/test/locale` in the source distribution contains a test suite for PostgreSQL's locale support.

Client applications that handle server-side errors by parsing the text of the error message will obviously have problems when the server's messages are in a different language. Authors of such applications are advised to make use of the error code scheme instead.

Maintaining catalogs of message translations requires the on-going efforts of many volunteers that want to see PostgreSQL speak their preferred language well. If messages in your language are currently not available or not fully translated, your assistance would be appreciated. If you want to help, refer to Chapter 47 or write to the developers' mailing list.

## 22.2. Character Set Support

The character set support in PostgreSQL allows you to store text in a variety of character sets (also called encodings), including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your PostgreSQL database cluster using `initdb`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

An important restriction, however, is that each database character set must be compatible with the server's `LC_CTYPE` setting. When `LC_CTYPE` is `C` or `POSIX`, any character set is allowed, but for other settings of

`LC_CTYPE` there is only one character set that will work correctly. Since the `LC_CTYPE` setting is frozen by `initdb`, the apparent flexibility to use different encodings in different databases of a cluster is more theoretical than real, except when you select `C` or `POSIX` locale (thus disabling any real locale awareness). It is likely that these mechanisms will be revisited in future versions of PostgreSQL.

## 22.2.1. Supported Character Sets

Table 22-1 shows the character sets available for use in PostgreSQL.

**Table 22-1. PostgreSQL Character Sets**

Name	Description	Language	Server?	Bytes/Char	Aliases
BIG5	Big Five	Traditional Chinese	No	1-2	WIN950, Windows950
EUC_CN	Extended UNIX Code-CN	Simplified Chinese	Yes	1-3	
EUC_JP	Extended UNIX Code-JP	Japanese	Yes	1-3	
EUC_JIS_2004	Extended UNIX Code-JP, JIS X 0213	Japanese	Yes	1-3	
EUC_KR	Extended UNIX Code-KR	Korean	Yes	1-3	
EUC_TW	Extended UNIX Code-TW	Traditional Chinese, Taiwanese	Yes	1-3	
GB18030	National Standard	Chinese	No	1-2	
GBK	Extended National Standard	Simplified Chinese	No	1-2	WIN936, Windows936
ISO_8859_5	ISO 8859-5, ECMA 113	Latin/Cyrillic	Yes	1	
ISO_8859_6	ISO 8859-6, ECMA 114	Latin/Arabic	Yes	1	
ISO_8859_7	ISO 8859-7, ECMA 118	Latin/Greek	Yes	1	
ISO_8859_8	ISO 8859-8, ECMA 121	Latin/Hebrew	Yes	1	
JOHAB	JOHAB	Korean (Hangul)	No	1-3	
KOI8	KOI8-R(U)	Cyrillic	Yes	1	KOI8R

Name	Description	Language	Server?	Bytes/Char	Aliases
LATIN1	ISO 8859-1, ECMA 94	Western European	Yes	1	ISO88591
LATIN2	ISO 8859-2, ECMA 94	Central European	Yes	1	ISO88592
LATIN3	ISO 8859-3, ECMA 94	South European	Yes	1	ISO88593
LATIN4	ISO 8859-4, ECMA 94	North European	Yes	1	ISO88594
LATIN5	ISO 8859-9, ECMA 128	Turkish	Yes	1	ISO88599
LATIN6	ISO 8859-10, ECMA 144	Nordic	Yes	1	ISO885910
LATIN7	ISO 8859-13	Baltic	Yes	1	ISO885913
LATIN8	ISO 8859-14	Celtic	Yes	1	ISO885914
LATIN9	ISO 8859-15	LATIN1 with Euro and accents	Yes	1	ISO885915
LATIN10	ISO 8859-16, ASRO SR 14111	Romanian	Yes	1	ISO885916
MULE_INTERNAL	Mule internal code	Multilingual Emacs	Yes	1-4	
SJIS	Shift JIS	Japanese	No	1-2	Mskanji, ShiftJIS, WIN932, Windows932
SHIFT_JIS_2000	Shift JIS, JIS X 0213	Japanese	No	1-2	
SQL_ASCII	unspecified (see text)	<i>any</i>	Yes	1	
UHC	Unified Hangul Code	Korean	No	1-2	WIN949, Windows949
UTF8	Unicode, 8-bit	<i>all</i>	Yes	1-4	Unicode
WIN866	Windows CP866	Cyrillic	Yes	1	ALT
WIN874	Windows CP874	Thai	Yes	1	
WIN1250	Windows CP1250	Central European	Yes	1	
WIN1251	Windows CP1251	Cyrillic	Yes	1	WIN

Name	Description	Language	Server?	Bytes/Char	Aliases
WIN1252	Windows CP1252	Western European	Yes	1	
WIN1253	Windows CP1253	Greek	Yes	1	
WIN1254	Windows CP1254	Turkish	Yes	1	
WIN1255	Windows CP1255	Hebrew	Yes	1	
WIN1256	Windows CP1256	Arabic	Yes	1	
WIN1257	Windows CP1257	Baltic	Yes	1	
WIN1258	Windows CP1258	Vietnamese	Yes	1	ABC, TCVN, TCVN5712, VSCII

Not all APIs support all the listed character sets. For example, the PostgreSQL JDBC driver does not support `MULE_INTERNAL`, `LATIN6`, `LATIN8`, and `LATIN10`.

The `SQL_ASCII` setting behaves considerably differently from the other settings. When the server character set is `SQL_ASCII`, the server interprets byte values 0-127 according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. No encoding conversion will be done when the setting is `SQL_ASCII`. Thus, this setting is not so much a declaration that a specific encoding is in use, as a declaration of ignorance about the encoding. In most cases, if you are working with any non-ASCII data, it is unwise to use the `SQL_ASCII` setting, because PostgreSQL will be unable to help you by converting or validating non-ASCII characters.

## 22.2.2. Setting the Character Set

`initdb` defines the default character set for a PostgreSQL cluster. For example,

```
initdb -E EUC_JP
```

sets the default character set (encoding) to `EUC_JP` (Extended Unix Code for Japanese). You can use `--encoding` instead of `-E` if you prefer to type longer option strings. If no `-E` or `--encoding` option is given, `initdb` attempts to determine the appropriate encoding to use based on the specified or default locale.

If you have selected `C` or `POSIX` locale, you can create a database with a different character set:

```
createdb -E EUC_KR korean
```

This will create a database named `korean` that uses the character set `EUC_KR`. Another way to accomplish this is to use this SQL command:

```
CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

The encoding for a database is stored in the system catalog `pg_database`. You can see it by using the `-l` option or the `\l` command of `psql`.

```
$ psql -l
          List of databases
 Database | Owner  | Encoding
-----+-----+-----
 euc_cn   | t-ishii | EUC_CN
 euc_jp   | t-ishii | EUC_JP
 euc_kr   | t-ishii | EUC_KR
 euc_tw   | t-ishii | EUC_TW
 mule_internal | t-ishii | MULE_INTERNAL
 postgres | t-ishii | EUC_JP
 regression | t-ishii | SQL_ASCII
 template1 | t-ishii | EUC_JP
 test     | t-ishii | EUC_JP
 utf8     | t-ishii | UTF8
(9 rows)
```

**Important:** On most modern operating systems, PostgreSQL can determine which character set is implied by an `LC_CTYPE` setting, and it will enforce that only the correct database encoding is used. On older systems it is your responsibility to ensure that you use the encoding expected by the locale you have selected. A mistake in this area is likely to lead to strange misbehavior of locale-dependent operations such as sorting.

PostgreSQL will allow superusers to create databases with `SQL_ASCII` encoding even when `LC_CTYPE` is not `C` or `POSIX`. As noted above, `SQL_ASCII` does not enforce that the data stored in the database has any particular encoding, and so this choice poses risks of locale-dependent misbehavior. Using this combination of settings is deprecated and may someday be forbidden altogether.

### 22.2.3. Automatic Character Set Conversion Between Server and Client

PostgreSQL supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the `pg_conversion` system catalog. PostgreSQL comes with some predefined conversions, as shown in Table 22-2. You can create a new conversion using the SQL command `CREATE CONVERSION`.

**Table 22-2. Client/Server Character Set Conversions**

Server Character Set	Available Client Character Sets
BIG5	<i>not supported as a server encoding</i>
EUC_CN	<i>EUC_CN</i> , <i>MULE_INTERNAL</i> , <i>UTF8</i>
EUC_JP	<i>EUC_JP</i> , <i>MULE_INTERNAL</i> , <i>SJIS</i> , <i>UTF8</i>
EUC_KR	<i>EUC_KR</i> , <i>MULE_INTERNAL</i> , <i>UTF8</i>

Server Character Set	Available Client Character Sets
EUC_TW	<i>EUC_TW</i> , BIG5, MULE_INTERNAL, UTF8
GB18030	<i>not supported as a server encoding</i>
GBK	<i>not supported as a server encoding</i>
ISO_8859_5	<i>ISO_8859_5</i> , KOI8, MULE_INTERNAL, UTF8, WIN866, WIN1251
ISO_8859_6	<i>ISO_8859_6</i> , UTF8
ISO_8859_7	<i>ISO_8859_7</i> , UTF8
ISO_8859_8	<i>ISO_8859_8</i> , UTF8
JOHAB	<i>JOHAB</i> , UTF8
KOI8	<i>KOI8</i> , ISO_8859_5, MULE_INTERNAL, UTF8, WIN866, WIN1251
LATIN1	<i>LATIN1</i> , MULE_INTERNAL, UTF8
LATIN2	<i>LATIN2</i> , MULE_INTERNAL, UTF8, WIN1250
LATIN3	<i>LATIN3</i> , MULE_INTERNAL, UTF8
LATIN4	<i>LATIN4</i> , MULE_INTERNAL, UTF8
LATIN5	<i>LATIN5</i> , UTF8
LATIN6	<i>LATIN6</i> , UTF8
LATIN7	<i>LATIN7</i> , UTF8
LATIN8	<i>LATIN8</i> , UTF8
LATIN9	<i>LATIN9</i> , UTF8
LATIN10	<i>LATIN10</i> , UTF8
MULE_INTERNAL	<i>MULE_INTERNAL</i> , BIG5, EUC_CN, EUC_JP, EUC_KR, EUC_TW, ISO_8859_5, KOI8, LATIN1 to LATIN4, SJIS, WIN866, WIN1250, WIN1251
SJIS	<i>not supported as a server encoding</i>
SQL_ASCII	<i>any (no conversion will be performed)</i>
UHC	<i>not supported as a server encoding</i>
UTF8	<i>all supported encodings</i>
WIN866	<i>WIN866</i> , ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN1251
WIN874	<i>WIN874</i> , UTF8
WIN1250	<i>WIN1250</i> , LATIN2, MULE_INTERNAL, UTF8
WIN1251	<i>WIN1251</i> , ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866
WIN1252	<i>WIN1252</i> , UTF8
WIN1253	<i>WIN1253</i> , UTF8
WIN1254	<i>WIN1254</i> , UTF8
WIN1255	<i>WIN1255</i> , UTF8
WIN1256	<i>WIN1256</i> , UTF8

Server Character Set	Available Client Character Sets
WIN1257	WIN1257, UTF8
WIN1258	WIN1258, UTF8

To enable automatic character set conversion, you have to tell PostgreSQL the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`. `\encoding` allows you to change client encoding on the fly. For example, to change the encoding to `SJIS`, type:

```
\encoding SJIS
```

- `libpq` (Section 30.9) has functions to control the client encoding.
- Using `SET client_encoding TO`. Setting the client encoding can be done with this SQL command:

```
SET CLIENT_ENCODING TO 'value';
```

Also you can use the standard SQL syntax `SET NAMES` for this purpose:

```
SET NAMES 'value';
```

To query the current client encoding:

```
SHOW client_encoding;
```

To return to the default encoding:

```
RESET client_encoding;
```

- Using `PGCLIENTENCODING`. If the environment variable `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)
- Using the configuration variable `client_encoding`. If the `client_encoding` variable is set, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1` — then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is disabled, regardless of the server's character set. Just as for the server, use of `SQL_ASCII` is unwise unless you are working with all-ASCII data.

## 22.2.4. Further Reading

These are good sources to start learning about various kinds of encoding systems.

UTF-8 is defined here.

# Chapter 23. Routine Database Maintenance Tasks

PostgreSQL, like any database software, requires that certain tasks be performed regularly to achieve optimum performance. The tasks discussed here are *required*, but they are repetitive in nature and can easily be automated using standard Unix tools such as cron scripts or Windows' Task Scheduler. But it is the database administrator's responsibility to set up appropriate scripts, and to check that they execute successfully.

One obvious maintenance task is creation of backup copies of the data on a regular schedule. Without a recent backup, you have no chance of recovery after a catastrophe (disk failure, fire, mistakenly dropping a critical table, etc.). The backup and recovery mechanisms available in PostgreSQL are discussed at length in Chapter 24.

The other main category of maintenance task is periodic "vacuuming" of the database. This activity is discussed in Section 23.1. Closely related to this is updating the statistics that will be used by the query planner, as discussed in Section 23.1.2.

Another task that might need periodic attention is log file management. This is discussed in Section 23.3.

PostgreSQL is low-maintenance compared to some other database management systems. Nonetheless, appropriate attention to these tasks will go far towards ensuring a pleasant and productive experience with the system.

## 23.1. Routine Vacuuming

PostgreSQL's *VACUUM* command has to run on a regular basis for several reasons:

1. To recover or reuse disk space occupied by updated or deleted rows.
2. To update data statistics used by the PostgreSQL query planner.
3. To protect against loss of very old data due to *transaction ID wraparound*.

The standard form of *VACUUM* can run in parallel with production database operations. Commands such as *SELECT*, *INSERT*, *UPDATE*, and *DELETE* will continue to function as normal, though you will not be able to modify the definition of a table with commands such as *ALTER TABLE ADD COLUMN* while it is being vacuumed. Also, *VACUUM* requires a substantial amount of I/O traffic, which can cause poor performance for other active sessions. There are configuration parameters that can be adjusted to reduce the performance impact of background vacuuming — see Section 18.4.4.

Fortunately, *The Auto-Vacuum Daemon* monitors table activity and performs *VACUUMS* when necessary. Autovacuum works dynamically so it is often better administration-scheduled vacuuming.

### 23.1.1. Recovering Disk Space

In normal PostgreSQL operation, an `UPDATE` or `DELETE` of a row does not immediately remove the old version of the row. This approach is necessary to gain the benefits of multiversion concurrency control (see Chapter 13): the row versions must not be deleted while it is still potentially visible to other transactions. But eventually, an outdated or deleted row version is no longer of interest to any transaction. The space it occupies must be reclaimed for reuse by new rows, to avoid infinite growth of disk space requirements. This is done by running `VACUUM`.

There are two variants of the `VACUUM` command. The first form, known as “lazy vacuum” or just `VACUUM`, marks dead data in tables and indexes for future reuse; it does *not* attempt to reclaim the space used by this dead data unless the space is at the end of the table and an exclusive table lock can be easily obtained. Unused space at the start or middle of the file does not result in the file being shortened and space returned to the operating system. This variant of `VACUUM` can be run concurrently with normal database operations.

The second form is the `VACUUM FULL` command. This uses a more aggressive algorithm for reclaiming the space consumed by dead row versions. Any space that is freed by `VACUUM FULL` is immediately returned to the operating system, and the table data is physically compacted on the disk. Unfortunately, this variant of the `VACUUM` command acquires an exclusive lock on each table while `VACUUM FULL` is processing it. Therefore, frequently using `VACUUM FULL` can have an extremely negative effect on the performance of concurrent database queries.

Fortunately, *The Auto-Vacuum Daemon* monitors table activity and performs `VACUUMS` when necessary. This eliminates the need for administrators to worry about disk space recovery in all but the most unusual cases.

For administrators who want to control `VACUUM` themselves, the standard form of `VACUUM` is best used to maintain a steady-state usage of disk space. If you need to return disk space to the operating system, you can use `VACUUM FULL`, but this is unwise if the table will just grow again in the future. Moderately-frequent standard `VACUUM` runs are a better approach than infrequent `VACUUM FULL` runs for maintaining heavily-updated tables. However, if some heavily-updated tables have gone too long with infrequent `VACUUM`, you can use `VACUUM FULL` or `CLUSTER` to get performance back (it is much slower to scan a table containing almost only dead rows).

For those not using autovacuum, one approach is to schedule a database-wide `VACUUM` once a day during low-usage period, supplemented by more frequent vacuuming of heavily-updated tables if necessary. (Some installations with extremely high update rates vacuum their busiest tables as often as once every few minutes.) If you have multiple databases in a cluster, don’t forget to `VACUUM` each one; the program *vacuumdb* might be helpful.

`VACUUM FULL` is recommended for cases where you know you have deleted the majority of rows in a table, so that the steady-state size of the table can be shrunk substantially with `VACUUM FULL`’s more aggressive approach. Use plain `VACUUM`, not `VACUUM FULL`, for routine vacuuming for space recovery.

If you have a table whose entire contents are deleted on a periodic basis, consider doing it with `TRUNCATE` rather than using `DELETE` followed by `VACUUM`. `TRUNCATE` removes the entire content of the table immediately, without requiring a subsequent `VACUUM` or `VACUUM FULL` to reclaim the now-unused disk space.

### 23.1.2. Updating Planner Statistics

The PostgreSQL query planner relies on statistical information about the contents of tables in order to

generate good plans for queries. These statistics are gathered by the *ANALYZE* command, which can be invoked by itself or as an optional step in *VACUUM*. It is important to have reasonably accurate statistics, otherwise poor choices of plans might degrade database performance.

As with vacuuming for space recovery, frequent updates of statistics are more useful for heavily-updated tables than for seldom-updated ones. But even for a heavily-updated table, there might be no need for statistics updates if the statistical distribution of the data is not changing much. A simple rule of thumb is to think about how much the minimum and maximum values of the columns in the table change. For example, a `timestamp` column that contains the time of row update will have a constantly-increasing maximum value as rows are added and updated; such a column will probably need more frequent statistics updates than, say, a column containing URLs for pages accessed on a website. The URL column might receive changes just as often, but the statistical distribution of its values probably changes relatively slowly.

It is possible to run *ANALYZE* on specific tables and even just specific columns of a table, so the flexibility exists to update some statistics more frequently than others if your application requires it. In practice, however, it is usually best to just analyze the entire database because it is a fast operation. It uses a statistical random sampling of the rows of a table rather than reading every single row.

**Tip:** Although per-column tweaking of *ANALYZE* frequency might not be very productive, you might well find it worthwhile to do per-column adjustment of the level of detail of the statistics collected by *ANALYZE*. Columns that are heavily used in *WHERE* clauses and have highly irregular data distributions might require a finer-grain data histogram than other columns. See *ALTER TABLE SET STATISTICS*.

Fortunately, *The Auto-Vacuum Daemon* monitors table activity and performs *ANALYZE*s when necessary. This eliminates the need for administrators to manually schedule *ANALYZE*.

For those not using autovacuum, one approach is to schedule a database-wide *ANALYZE* once a day at a low-usage time of day; this can usefully be combined with a nightly *VACUUM*. However, sites with relatively slowly changing table statistics might find that this is overkill, and that less-frequent *ANALYZE* runs are sufficient.

### 23.1.3. Preventing Transaction ID Wraparound Failures

PostgreSQL's MVCC transaction semantics depend on being able to compare transaction ID (XID) numbers: a row version with an insertion XID greater than the current transaction's XID is "in the future" and should not be visible to the current transaction. But since transaction IDs have limited size (32 bits at this writing) a cluster that runs for a long time (more than 4 billion transactions) would suffer *transaction ID wraparound*: the XID counter wraps around to zero, and all of a sudden transactions that were in the past appear to be in the future — which means their outputs become invisible. In short, catastrophic data loss. (Actually the data is still there, but that's cold comfort if you cannot get at it.) To avoid this, it is necessary to vacuum every table in every database at least once every two billion transactions.

The reason that periodic vacuuming solves the problem is that PostgreSQL distinguishes a special XID `FrozenXID`. This XID is always considered older than every normal XID. Normal XIDs are compared using modulo-2<sup>31</sup> arithmetic. This means that for every normal XID, there are two billion XIDs that are "older" and two billion that are "newer"; another way to say it is that the normal XID space is circular with no endpoint. Therefore, once a row version has been created with a particular normal XID, the row version will appear to be "in the past" for the next two billion transactions, no matter which normal XID

we are talking about. If the row version still exists after more than two billion transactions, it will suddenly appear to be in the future. To prevent data loss, old row versions must be reassigned the `XID_FrozenXID` sometime before they reach the two-billion-transactions-old mark. Once they are assigned this special XID, they will appear to be “in the past” to all normal transactions regardless of wraparound issues, and so such row versions will be good until deleted, no matter how long that is. This reassignment of old XIDs is handled by `VACUUM`.

`VACUUM`’s behavior is controlled by the configuration parameter `vacuum_freeze_min_age`: any XID older than `vacuum_freeze_min_age` transactions is replaced by `FrozenXID`. Larger values of `vacuum_freeze_min_age` preserve transactional information longer, while smaller values increase the number of transactions that can elapse before the table must be vacuumed again.

The maximum time that a table can go unvacuumed is two billion transactions minus the `vacuum_freeze_min_age` that was used when it was last vacuumed. If it were to go unvacuumed for longer than that, data loss could result. To ensure that this does not happen, *The Auto-Vacuum Daemon* is invoked on any table that might contain XIDs older than the age specified by the configuration parameter `autovacuum_freeze_max_age`. (This will happen even if `autovacuum` is otherwise disabled.)

This implies that if a table is not otherwise vacuumed, `autovacuum` will be invoked on it approximately once every `autovacuum_freeze_max_age` minus `vacuum_freeze_min_age` transactions. For tables that are regularly vacuumed for space reclamation purposes, this is of little importance. However, for static tables (including tables that receive inserts, but no updates or deletes), there is no need for vacuuming for space reclamation, and so it can be useful to try to maximize the interval between forced `autovacuum`s on very large static tables. Obviously one can do this either by increasing `autovacuum_freeze_max_age` or by decreasing `vacuum_freeze_min_age`.

The sole disadvantage of increasing `autovacuum_freeze_max_age` is that the `pg_clog` subdirectory of the database cluster will take more space, because it must store the commit status for all transactions back to the `autovacuum_freeze_max_age` horizon. The commit status uses two bits per transaction, so if `autovacuum_freeze_max_age` has its maximum allowed value of a little less than two billion, `pg_clog` can be expected to grow to about half a gigabyte. If this is trivial compared to your total database size, setting `autovacuum_freeze_max_age` to its maximum allowed value is recommended. Otherwise, set it depending on what you are willing to allow for `pg_clog` storage. (The default, 200 million transactions, translates to about 50MB of `pg_clog` storage.)

One disadvantage of decreasing `vacuum_freeze_min_age` is that it might cause `VACUUM` to do useless work: changing a table row’s XID to `FrozenXID` is a waste of time if the row is modified soon thereafter (causing it to acquire a new XID). So the setting should be large enough that rows are not frozen until they are unlikely to change any more. Another disadvantage of decreasing this setting is that details about exactly which transaction inserted or modified a row will be lost sooner. This information sometimes comes in handy, particularly when trying to analyze what went wrong after a database failure. For these two reasons, decreasing this setting is not recommended except for completely static tables.

To track the age of the oldest XIDs in a database, `VACUUM` stores XID statistics in the system tables `pg_class` and `pg_database`. In particular, the `relfrozenxid` column of a table’s `pg_class` row contains the freeze cutoff XID that was used by the last `VACUUM` for that table. All normal XIDs older than this cutoff XID are guaranteed to have been replaced by `FrozenXID` within the table. Similarly, the `datfrozenxid` column of a database’s `pg_database` row is a lower bound on the normal XIDs appearing in that database — it is just the minimum of the per-table `relfrozenxid` values within the database. A convenient way to examine this information is to execute queries such as:

```
SELECT relname, age(relfrozenxid) FROM pg_class WHERE relkind = 'r';
```

```
SELECT datname, age(datfrozenxid) FROM pg_database;
```

The `age` column measures the number of transactions from the cutoff XID to the current transaction's XID. Immediately after a `VACUUM`, `age(relfrozenxid)` should be a little more than the `vacuum_freeze_min_age` setting that was used (more by the number of transactions started since the `VACUUM` started). If `age(relfrozenxid)` exceeds `autovacuum_freeze_max_age`, an autovacuum will soon be forced for the table.

If for some reason autovacuum fails to clear old XIDs from a table, the system will begin to emit warning messages like this when the database's oldest XIDs reach ten million transactions from the wraparound point:

```
WARNING: database "mydb" must be vacuumed within 177009986 transactions
HINT: To avoid a database shutdown, execute a full-database VACUUM in "mydb".
```

If these warnings are ignored, the system will shut down and refuse to execute any new transactions once there are fewer than 1 million transactions left until wraparound:

```
ERROR: database is not accepting commands to avoid wraparound data loss in database "mydb"
HINT: Stop the postmaster and use a standalone backend to VACUUM in "mydb".
```

The 1-million-transaction safety margin exists to let the administrator recover without data loss, by manually executing the required `VACUUM` commands. However, since the system will not execute commands once it has gone into the safety shutdown mode, the only way to do this is to stop the server and use a single-user backend to execute `VACUUM`. The shutdown mode is not enforced by a single-user backend. See the postgres reference page for details about using a single-user backend.

### 23.1.4. The Auto-Vacuum Daemon

Beginning in PostgreSQL 8.1, there is an optional feature called *autovacuum*, whose purpose is to automate the execution of `VACUUM` and `ANALYZE` commands. When enabled, autovacuum checks for tables that have had a large number of inserted, updated or deleted tuples. These checks use the statistics collection facility; therefore, autovacuum cannot be used unless `track_counts` is set to `true`. In the default configuration, autovacuuming is enabled and the related configuration parameters are appropriately set.

Beginning in PostgreSQL 8.3, autovacuum has a multiprocess architecture: There is a daemon process, called the *autovacuum launcher*, which is in charge of starting an *autovacuum worker* process on each database every `autovacuum_naptime` seconds. On each run, the worker process checks each table within that database, and `VACUUM` or `ANALYZE` commands are issued as needed.

The `autovacuum_max_workers` setting limits how many workers may be running at any time. If several large tables all become eligible for vacuuming in a short amount of time, all autovacuum workers may end up vacuuming those tables for a very long time. This would result in other tables and databases not being vacuumed until a worker became available. There is not a limit on how many workers might be in a single database, but workers do try to avoid repeating work that has already been done by other workers. Note that the number of running workers does not count towards the `max_connections` nor the `superuser_reserved_connections` limits.

Tables whose `relfrozenxid` value is more than `autovacuum_freeze_max_age` transactions old are always vacuumed. Otherwise, two conditions are used to determine which operation(s) to apply. If the

number of obsolete tuples since the last `VACUUM` exceeds the “vacuum threshold”, the table is vacuumed. The vacuum threshold is defined as:

$$\text{vacuum threshold} = \text{vacuum base threshold} + \text{vacuum scale factor} * \text{number of tuples}$$

where the vacuum base threshold is `autovacuum_vacuum_threshold`, the vacuum scale factor is `autovacuum_vacuum_scale_factor`, and the number of tuples is `pg_class.reltuples`. The number of obsolete tuples is obtained from the statistics collector; it is a semi-accurate count updated by each `UPDATE` and `DELETE` operation. (It is only semi-accurate because some information might be lost under heavy load.) For analyze, a similar condition is used: the threshold, defined as:

$$\text{analyze threshold} = \text{analyze base threshold} + \text{analyze scale factor} * \text{number of tuples}$$

is compared to the total number of tuples inserted or updated since the last `ANALYZE`.

The default thresholds and scale factors are taken from `postgresql.conf`, but it is possible to override them on a table-by-table basis by making entries in the system catalog `pg_autovacuum`. If a `pg_autovacuum` row exists for a particular table, the settings it specifies are applied; otherwise the global settings are used. See Section 18.9 for more details on the global settings.

Besides the base threshold values and scale factors, there are five more parameters that can be set for each table in `pg_autovacuum`. The first, `pg_autovacuum.enabled`, can be set to `false` to instruct the autovacuum daemon to skip that particular table entirely. In this case autovacuum will only touch the table if it must do so to prevent transaction ID wraparound. The next two parameters, the vacuum cost delay (`pg_autovacuum.vac_cost_delay`) and the vacuum cost limit (`pg_autovacuum.vac_cost_limit`), are used to set table-specific values for the *Cost-Based Vacuum Delay* feature. The last two parameters, (`pg_autovacuum.freeze_min_age`) and (`pg_autovacuum.freeze_max_age`), are used to set table-specific values for `vacuum_freeze_min_age` and `autovacuum_freeze_max_age` respectively.

If any of the values in `pg_autovacuum` are set to a negative number, or if a row is not present at all in `pg_autovacuum` for any particular table, the corresponding values from `postgresql.conf` are used.

There is not currently any support for making `pg_autovacuum` entries, except by doing manual `INSERTS` into the catalog. This feature will be improved in future releases, and it is likely that the catalog definition will change.

### Caution

The contents of the `pg_autovacuum` system catalog are currently not saved in database dumps created by the tools `pg_dump` and `pg_dumpall`. If you want to preserve them across a dump/reload cycle, make sure you dump the catalog manually.

When multiple workers are running, the cost limit is “balanced” among all the running workers, so that the total impact on the system is the same, regardless of the number of workers actually running.

## 23.2. Routine Reindexing

In some situations it is worthwhile to rebuild indexes periodically with the `REINDEX` command.

In PostgreSQL releases before 7.4, periodic reindexing was frequently necessary to avoid “index bloat”, due to lack of internal space reclamation in B-tree indexes. Any situation in which the range of index keys changed over time — for example, an index on timestamps in a table where old entries are eventually deleted — would result in bloat, because index pages for no-longer-needed portions of the key range were not reclaimed for re-use. Over time, the index size could become indefinitely much larger than the amount of useful data in it.

In PostgreSQL 7.4 and later, index pages that have become completely empty are reclaimed for re-use. There is still a possibility for inefficient use of space: if all but a few index keys on a page have been deleted, the page remains allocated. So a usage pattern in which all but a few keys in each range are eventually deleted will see poor use of space. For such usage patterns, periodic reindexing is recommended.

The potential for bloat in non-B-tree indexes has not been well characterized. It is a good idea to keep an eye on the index’s physical size when using any non-B-tree index type.

Also, for B-tree indexes a freshly-constructed index is somewhat faster to access than one that has been updated many times, because logically adjacent pages are usually also physically adjacent in a newly built index. (This consideration does not currently apply to non-B-tree indexes.) It might be worthwhile to reindex periodically just to improve access speed.

## 23.3. Log File Maintenance

It is a good idea to save the database server’s log output somewhere, rather than just routing it to `/dev/null`. The log output is invaluable when it comes time to diagnose problems. However, the log output tends to be voluminous (especially at higher debug levels) and you won’t want to save it indefinitely. You need to “rotate” the log files so that new log files are started and old ones removed after a reasonable period of time.

If you simply direct the `stderr` of `postgres` into a file, you will have log output, but the only way to truncate the log file is to stop and restart the server. This might be OK if you are using PostgreSQL in a development environment, but few production servers would find this behavior acceptable.

A better approach is to send the server’s `stderr` output to some type of log rotation program. There is a built-in log rotation program, which you can use by setting the configuration parameter `logging_collector` to `true` in `postgresql.conf`. The control parameters for this program are described in Section 18.7.1. You can also use this approach to capture the log data in machine readable CSV format.

Alternatively, you might prefer to use an external log rotation program, if you have one that you are already using with other server software. For example, the `rotatelogs` tool included in the Apache distribution can be used with PostgreSQL. To do this, just pipe the server’s `stderr` output to the desired program. If you start the server with `pg_ctl`, then `stderr` is already redirected to `stdout`, so you just need a pipe command, for example:

```
pg_ctl start | rotatelogs /var/log/pgsql_log 86400
```

Another production-grade approach to managing log output is to send it all to `syslog` and let `syslog` deal with file rotation. To do this, set the configuration parameter `log_destination` to `syslog` (to log to `syslog` only) in `postgresql.conf`. Then you can send a `SIGHUP` signal to the `syslog` daemon whenever

you want to force it to start writing a new log file. If you want to automate log rotation, the logrotate program can be configured to work with log files from syslog.

On many systems, however, syslog is not very reliable, particularly with large log messages; it might truncate or drop messages just when you need them the most. Also, on Linux, syslog will sync each message to disk, yielding poor performance. (You can use a `-` at the start of the file name in the syslog configuration file to disable this behavior.)

Note that all the solutions described above take care of starting new log files at configurable intervals, but they do not handle deletion of old, no-longer-interesting log files. You will probably want to set up a batch job to periodically delete old log files. Another possibility is to configure the rotation program so that old log files are overwritten cyclically.

# Chapter 24. Backup and Restore

As with everything that contains valuable data, PostgreSQL databases should be backed up regularly. While the procedure is essentially simple, it is important to have a clear understanding of the underlying techniques and assumptions.

There are three fundamentally different approaches to backing up PostgreSQL data:

- SQL dump
- File system level backup
- Continuous archiving

Each has its own strengths and weaknesses. Each is discussed in turn below.

## 24.1. SQL Dump

The idea behind this dump method is to generate a text file with SQL commands that, when fed back to the server, will recreate the database in the same state as it was at the time of the dump. PostgreSQL provides the utility program `pg_dump` for this purpose. The basic usage of this command is:

```
pg_dump dbname > outfile
```

As you see, `pg_dump` writes its results to the standard output. We will see below how this can be useful.

`pg_dump` is a regular PostgreSQL client application (albeit a particularly clever one). This means that you can do this backup procedure from any remote host that has access to the database. But remember that `pg_dump` does not operate with special permissions. In particular, it must have read access to all tables that you want to back up, so in practice you almost always have to run it as a database superuser.

To specify which database server `pg_dump` should contact, use the command line options `-h host` and `-p port`. The default host is the local host or whatever your `PGHOST` environment variable specifies. Similarly, the default port is indicated by the `PGPORT` environment variable or, failing that, by the compiled-in default. (Conveniently, the server will normally have the same compiled-in default.)

Like any other PostgreSQL client application, `pg_dump` will by default connect with the database user name that is equal to the current operating system user name. To override this, either specify the `-U` option or set the environment variable `PGUSER`. Remember that `pg_dump` connections are subject to the normal client authentication mechanisms (which are described in Chapter 21).

Dumps created by `pg_dump` are internally consistent, that is, the dump represents a snapshot of the database as of the time `pg_dump` begins running. `pg_dump` does not block other operations on the database while it is working. (Exceptions are those operations that need to operate with an exclusive lock, such as most forms of `ALTER TABLE`.)

**Important:** If your database schema relies on OIDs (for instance as foreign keys) you must instruct `pg_dump` to dump the OIDs as well. To do this, use the `-o` command line option.

### 24.1.1. Restoring the dump

The text files created by `pg_dump` are intended to be read in by the `psql` program. The general command form to restore a dump is

```
psql dbname < infile
```

where *infile* is what you used as *outfile* for the `pg_dump` command. The database *dbname* will not be created by this command, so you must create it yourself from `template0` before executing `psql` (e.g., with `createdb -T template0 dbname`). `psql` supports options similar to `pg_dump`'s for specifying the database server to connect to and the user name to use. See the `psql` reference page for more information.

Before restoring a SQL dump, all the users who own objects or were granted permissions on objects in the dumped database must already exist. If they do not, then the restore will fail to recreate the objects with the original ownership and/or permissions. (Sometimes this is what you want, but usually it is not.)

By default, the `psql` script will continue to execute after an SQL error is encountered. You might wish to use the following command at the top of the script to alter that behaviour and have `psql` exit with an exit status of 3 if an SQL error occurs:

```
\set ON_ERROR_STOP
```

Either way, you will have an only partially restored database. Alternatively, you can specify that the whole dump should be restored as a single transaction, so the restore is either fully completed or fully rolled back. This mode can be specified by passing the `-1` or `--single-transaction` command-line options to `psql`. When using this mode, be aware that even the smallest of errors can rollback a restore that has already run for many hours. However, that might still be preferable to manually cleaning up a complex database after a partially restored dump.

The ability of `pg_dump` and `psql` to write to or read from pipes makes it possible to dump a database directly from one server to another, for example:

```
pg_dump -h host1 dbname | psql -h host2 dbname
```

**Important:** The dumps produced by `pg_dump` are relative to `template0`. This means that any languages, procedures, etc. added via `template1` will also be dumped by `pg_dump`. As a result, when restoring, if you are using a customized `template1`, you must create the empty database from `template0`, as in the example above.

After restoring a backup, it is wise to run `ANALYZE` on each database so the query optimizer has useful statistics. An easy way to do this is to run `vacuumdb -a -z`; this is equivalent to running `VACUUM ANALYZE` on each database manually. For more advice on how to load large amounts of data into PostgreSQL efficiently, refer to Section 14.4.

### 24.1.2. Using pg\_dumpall

`pg_dump` dumps only a single database at a time, and it does not dump information about roles or tablespaces (because those are cluster-wide rather than per-database). To support convenient dumping of

the entire contents of a database cluster, the `pg_dumpall` program is provided. `pg_dumpall` backs up each database in a given cluster, and also preserves cluster-wide data such as role and tablespace definitions. The basic usage of this command is:

```
pg_dumpall > outfile
```

The resulting dump can be restored with `psql`:

```
psql -f infile postgres
```

(Actually, you can specify any existing database name to start from, but if you are reloading into an empty cluster then `postgres` should usually be used.) It is always necessary to have database superuser access when restoring a `pg_dumpall` dump, as that is required to restore the role and tablespace information. If you use tablespaces, be careful that the tablespace paths in the dump are appropriate for the new installation.

`pg_dumpall` works by emitting commands to re-create roles, tablespaces, and empty databases, then invoking `pg_dump` for each database. This means that while each database will be internally consistent, the snapshots of different databases might not be exactly in-sync.

### 24.1.3. Handling large databases

Since PostgreSQL allows tables larger than the maximum file size on your system, it can be problematic to dump such a table to a file, since the resulting file will likely be larger than the maximum size allowed by your system. Since `pg_dump` can write to the standard output, you can use standard Unix tools to work around this possible problem. There are several ways to do it:

**Use compressed dumps.** You can use your favorite compression program, for example `gzip`:

```
pg_dump dbname | gzip > filename.gz
```

Reload with:

```
gunzip -c filename.gz | psql dbname
```

or:

```
cat filename.gz | gunzip | psql dbname
```

**Use `split`.** The `split` command allows you to split the output into pieces that are acceptable in size to the underlying file system. For example, to make chunks of 1 megabyte:

```
pg_dump dbname | split -b 1m - filename
```

Reload with:

```
cat filename* | psql dbname
```

**Use `pg_dump`'s custom dump format.** If PostgreSQL was built on a system with the `zlib` compression library installed, the custom dump format will compress data as it writes it to the output file. This will

produce dump file sizes similar to using `gzip`, but it has the added advantage that tables can be restored selectively. The following command dumps a database using the custom dump format:

```
pg_dump -Fc dbname > filename
```

A custom-format dump is not a script for `psql`, but instead must be restored with `pg_restore`, for example:

```
pg_restore -d dbname filename
```

See the `pg_dump` and `pg_restore` reference pages for details.

For very large databases, you might need to combine `split` with one of the other two approaches.

## 24.2. File System Level Backup

An alternative backup strategy is to directly copy the files that PostgreSQL uses to store the data in the database. In Section 17.2 it is explained where these files are located, but you have probably found them already if you are interested in this method. You can use whatever method you prefer for doing usual file system backups, for example:

```
tar -cf backup.tar /usr/local/pgsql/data
```

There are two restrictions, however, which make this method impractical, or at least inferior to the `pg_dump` method:

1. The database server *must* be shut down in order to get a usable backup. Half-way measures such as disallowing all connections will *not* work (in part because `tar` and similar tools do not take an atomic snapshot of the state of the file system, but also because of internal buffering within the server). Information about stopping the server can be found in Section 17.5. Needless to say that you also need to shut down the server before restoring the data.
2. If you have dug into the details of the file system layout of the database, you might be tempted to try to back up or restore only certain individual tables or databases from their respective files or directories. This will *not* work because the information contained in these files contains only half the truth. The other half is in the commit log files `pg_clog/*`, which contain the commit status of all transactions. A table file is only usable with this information. Of course it is also impossible to restore only a table and the associated `pg_clog` data because that would render all other tables in the database cluster useless. So file system backups only work for complete backup and restoration of an entire database cluster.

An alternative file-system backup approach is to make a “consistent snapshot” of the data directory, if the file system supports that functionality (and you are willing to trust that it is implemented correctly). The typical procedure is to make a “frozen snapshot” of the volume containing the database, then copy the whole data directory (not just parts, see above) from the snapshot to a backup device, then release the frozen snapshot. This will work even while the database server is running. However, a backup created in this way saves the database files in a state where the database server was not properly shut down; therefore,

when you start the database server on the backed-up data, it will think the previous server instance had crashed and replay the WAL log. This is not a problem, just be aware of it (and be sure to include the WAL files in your backup).

If your database is spread across multiple file systems, there might not be any way to obtain exactly-simultaneous frozen snapshots of all the volumes. For example, if your data files and WAL log are on different disks, or if tablespaces are on different file systems, it might not be possible to use snapshot backup because the snapshots *must* be simultaneous. Read your file system documentation very carefully before trusting to the consistent-snapshot technique in such situations. The safest approach is to shut down the database server for long enough to establish all the frozen snapshots.

Another option is to use rsync to perform a file system backup. This is done by first running rsync while the database server is running, then shutting down the database server just long enough to do a second rsync. The second rsync will be much quicker than the first, because it has relatively little data to transfer, and the end result will be consistent because the server was down. This method allows a file system backup to be performed with minimal downtime.

Note that a file system backup will not necessarily be smaller than an SQL dump. On the contrary, it will most likely be larger. (pg\_dump does not need to dump the contents of indexes for example, just the commands to recreate them.) However, taking a file system backup might be faster.

## 24.3. Continuous Archiving and Point-In-Time Recovery (PITR)

At all times, PostgreSQL maintains a *write ahead log* (WAL) in the `pg_xlog/` subdirectory of the cluster's data directory. The log describes every change made to the database's data files. This log exists primarily for crash-safety purposes: if the system crashes, the database can be restored to consistency by "replaying" the log entries made since the last checkpoint. However, the existence of the log makes it possible to use a third strategy for backing up databases: we can combine a file-system-level backup with backup of the WAL files. If recovery is needed, we restore the backup and then replay from the backed-up WAL files to bring the backup up to current time. This approach is more complex to administer than either of the previous approaches, but it has some significant benefits:

- We do not need a perfectly consistent backup as the starting point. Any internal inconsistency in the backup will be corrected by log replay (this is not significantly different from what happens during crash recovery). So we don't need file system snapshot capability, just tar or a similar archiving tool.
- Since we can string together an indefinitely long sequence of WAL files for replay, continuous backup can be achieved simply by continuing to archive the WAL files. This is particularly valuable for large databases, where it might not be convenient to take a full backup frequently.
- There is nothing that says we have to replay the WAL entries all the way to the end. We could stop the replay at any point and have a consistent snapshot of the database as it was at that time. Thus, this technique supports *point-in-time recovery*: it is possible to restore the database to its state at any time since your base backup was taken.
- If we continuously feed the series of WAL files to another machine that has been loaded with the same base backup file, we have a *warm standby* system: at any point we can bring up the second machine

and it will have a nearly-current copy of the database.

As with the plain file-system-backup technique, this method can only support restoration of an entire database cluster, not a subset. Also, it requires a lot of archival storage: the base backup might be bulky, and a busy system will generate many megabytes of WAL traffic that have to be archived. Still, it is the preferred backup technique in many situations where high reliability is needed.

To recover successfully using continuous archiving (also called “online backup” by many database vendors), you need a continuous sequence of archived WAL files that extends back at least as far as the start time of your backup. So to get started, you should set up and test your procedure for archiving WAL files *before* you take your first base backup. Accordingly, we first discuss the mechanics of archiving WAL files.

### 24.3.1. Setting up WAL archiving

In an abstract sense, a running PostgreSQL system produces an indefinitely long sequence of WAL records. The system physically divides this sequence into WAL *segment files*, which are normally 16MB apiece (although the segment size can be altered when building PostgreSQL). The segment files are given numeric names that reflect their position in the abstract WAL sequence. When not using WAL archiving, the system normally creates just a few segment files and then “recycles” them by renaming no-longer-needed segment files to higher segment numbers. It’s assumed that a segment file whose contents precede the checkpoint-before-last is no longer of interest and can be recycled.

When archiving WAL data, we need to capture the contents of each segment file once it is filled, and save that data somewhere before the segment file is recycled for reuse. Depending on the application and the available hardware, there could be many different ways of “saving the data somewhere”: we could copy the segment files to an NFS-mounted directory on another machine, write them onto a tape drive (ensuring that you have a way of identifying the original name of each file), or batch them together and burn them onto CDs, or something else entirely. To provide the database administrator with as much flexibility as possible, PostgreSQL tries not to make any assumptions about how the archiving will be done. Instead, PostgreSQL lets the administrator specify a shell command to be executed to copy a completed segment file to wherever it needs to go. The command could be as simple as a `cp`, or it could invoke a complex shell script — it’s all up to you.

To enable WAL archiving, set the `archive_mode` configuration parameter to `on`, and specify the shell command to use in the `archive_command` configuration parameter. In practice these settings will always be placed in the `postgresql.conf` file. In `archive_command`, any `%p` is replaced by the path name of the file to archive, while any `%f` is replaced by the file name only. (The path name is relative to the current working directory, i.e., the cluster’s data directory.) Write `%%` if you need to embed an actual `%` character in the command. The simplest useful command is something like:

```
archive_command = 'cp -i %p /mnt/server/archivedir/%f </dev/null'
```

which will copy archivable WAL segments to the directory `/mnt/server/archivedir`. (This is an example, not a recommendation, and might not work on all platforms.) After the `%p` and `%f` parameters have been replaced, the actual command executed might look like this:

```
cp -i pg_xlog/00000001000000A9000000065 /mnt/server/archivedir/00000001000000A9000000065 </dev/null
```

A similar command will be generated for each new file to be archived.

The archive command will be executed under the ownership of the same user that the PostgreSQL server is running as. Since the series of WAL files being archived contains effectively everything in your database, you will want to be sure that the archived data is protected from prying eyes; for example, archive into a directory that does not have group or world read access.

It is important that the archive command return zero exit status if and only if it succeeded. Upon getting a zero result, PostgreSQL will assume that the WAL segment file has been successfully archived, and will remove or recycle it. However, a nonzero status tells PostgreSQL that the file was not archived; it will try again periodically until it succeeds.

The archive command should generally be designed to refuse to overwrite any pre-existing archive file. This is an important safety feature to preserve the integrity of your archive in case of administrator error (such as sending the output of two different servers to the same archive directory). It is advisable to test your proposed archive command to ensure that it indeed does not overwrite an existing file, *and that it returns nonzero status in this case*. We have found that `cp -i` does this correctly on some platforms but not others. If the chosen command does not itself handle this case correctly, you should add a command to test for pre-existence of the archive file. For example, something like:

```
archive_command = 'test ! -f ../%f && cp %p ../%f'
```

works correctly on most Unix variants.

While designing your archiving setup, consider what will happen if the archive command fails repeatedly because some aspect requires operator intervention or the archive runs out of space. For example, this could occur if you write to tape without an autochanger; when the tape fills, nothing further can be archived until the tape is swapped. You should ensure that any error condition or request to a human operator is reported appropriately so that the situation can be resolved reasonably quickly. The `pg_xlog/` directory will continue to fill with WAL segment files until the situation is resolved. (If the filesystem containing `pg_xlog/` fills up, PostgreSQL will do a PANIC shutdown. No prior transactions will be lost, but the database will be unavailable until you free some space.)

The speed of the archiving command is not important, so long as it can keep up with the average rate at which your server generates WAL data. Normal operation continues even if the archiving process falls a little behind. If archiving falls significantly behind, this will increase the amount of data that would be lost in the event of a disaster. It will also mean that the `pg_xlog/` directory will contain large numbers of not-yet-archived segment files, which could eventually exceed available disk space. You are advised to monitor the archiving process to ensure that it is working as you intend.

In writing your archive command, you should assume that the file names to be archived can be up to 64 characters long and can contain any combination of ASCII letters, digits, and dots. It is not necessary to remember the original relative path (`%p`) but it is necessary to remember the file name (`%f`).

Note that although WAL archiving will allow you to restore any modifications made to the data in your PostgreSQL database, it will not restore changes made to configuration files (that is, `postgresql.conf`, `pg_hba.conf` and `pg_ident.conf`), since those are edited manually rather than through SQL operations. You might wish to keep the configuration files in a location that will be backed up by your regular file system backup procedures. See Section 18.2 for how to relocate the configuration files.

The archive command is only invoked on completed WAL segments. Hence, if your server generates only little WAL traffic (or has slack periods where it does so), there could be a long delay between the completion of a transaction and its safe recording in archive storage. To put a limit on how old unarchived

data can be, you can set `archive_timeout` to force the server to switch to a new WAL segment file at least that often. Note that archived files that are ended early due to a forced switch are still the same length as completely full files. It is therefore unwise to set a very short `archive_timeout` — it will bloat your archive storage. `archive_timeout` settings of a minute or so are usually reasonable.

Also, you can force a segment switch manually with `pg_switch_xlog`, if you want to ensure that a just-finished transaction is archived as soon as possible. Other utility functions related to WAL management are listed in Table 9-53.

When `archive_mode` is `off` some SQL commands are optimized to avoid WAL logging, as described in Section 14.4.7. If archiving were turned on during execution of one of these statements, WAL would not contain enough information for archive recovery. (Crash recovery is unaffected.) For this reason, `archive_mode` can only be changed at server start. However, `archive_command` can be changed with a configuration file reload. If you wish to temporarily stop archiving, one way to do it is to set `archive_command` to the empty string (`''`). This will cause WAL files to accumulate in `pg_xlog/` until a working `archive_command` is re-established.

### 24.3.2. Making a Base Backup

The procedure for making a base backup is relatively simple:

1. Ensure that WAL archiving is enabled and working.
2. Connect to the database as a superuser, and issue the command:

```
SELECT pg_start_backup('label');
```

where `label` is any string you want to use to uniquely identify this backup operation. (One good practice is to use the full path where you intend to put the backup dump file.) `pg_start_backup` creates a *backup label* file, called `backup_label`, in the cluster directory with information about your backup.

It does not matter which database within the cluster you connect to to issue this command. You can ignore the result returned by the function; but if it reports an error, deal with that before proceeding.

`pg_start_backup` can take a long time to finish. This is because it performs a checkpoint, and the I/O required for a checkpoint will be spread out over a significant period of time, by default half your inter-checkpoint interval (see the configuration parameter `checkpoint_completion_target`). Usually this is what you want because it minimizes the impact on query processing. If you just want to start the backup as soon as possible, execute a `CHECKPOINT` command (which performs a checkpoint as quickly as possible) and then immediately execute `pg_start_backup`. Then there will be very little for `pg_start_backup`'s checkpoint to do, and it won't take long.

3. Perform the backup, using any convenient file-system-backup tool such as `tar` or `cpio`. It is neither necessary nor desirable to stop normal operation of the database while you do this.
4. Again connect to the database as a superuser, and issue the command:

```
SELECT pg_stop_backup();
```

This terminates the backup mode and performs an automatic switch to the next WAL segment. The reason for the switch is to arrange that the last WAL segment file written during the backup interval is immediately ready to archive.

5. Once the WAL segment files used during the backup are archived, you are done. The file identified by `pg_stop_backup`'s result is the last segment that needs to be archived to complete the backup. Archival of these files will happen automatically, since you have already configured `archive_command`. In many cases, this happens fairly quickly, but you are advised to monitor your archival system to ensure this has taken place so that you can be certain you have a complete backup.

Some backup tools that you might wish to use emit warnings or errors if the files they are trying to copy change while the copy proceeds. This situation is normal, and not an error, when taking a base backup of an active database; so you need to ensure that you can distinguish complaints of this sort from real errors. For example, some versions of `rsync` return a separate exit code for “vanished source files”, and you can write a driver script to accept this exit code as a non-error case. Also, some versions of GNU `tar` return an error code indistinguishable from a fatal error if a file was truncated while `tar` was copying it. Fortunately, GNU `tar` versions 1.16 and later exit with 1 if a file was changed during the backup, and 2 for other errors.

It is not necessary to be very concerned about the amount of time elapsed between `pg_start_backup` and the start of the actual backup, nor between the end of the backup and `pg_stop_backup`; a few minutes' delay won't hurt anything. (However, if you normally run the server with `full_page_writes` disabled, you might notice a drop in performance between `pg_start_backup` and `pg_stop_backup`, since `full_page_writes` is effectively forced on during backup mode.) You must ensure that these steps are carried out in sequence without any possible overlap, or you will invalidate the backup.

Be certain that your backup dump includes all of the files underneath the database cluster directory (e.g., `/usr/local/pgsql/data`). If you are using tablespaces that do not reside underneath this directory, be careful to include them as well (and be sure that your backup dump archives symbolic links as links, otherwise the restore will mess up your tablespaces).

You can, however, omit from the backup dump the files within the `pg_xlog/` subdirectory of the cluster directory. This slight complication is worthwhile because it reduces the risk of mistakes when restoring. This is easy to arrange if `pg_xlog/` is a symbolic link pointing to someplace outside the cluster directory, which is a common setup anyway for performance reasons.

To make use of the backup, you will need to keep around all the WAL segment files generated during and after the file system backup. To aid you in doing this, the `pg_stop_backup` function creates a *backup history file* that is immediately stored into the WAL archive area. This file is named after the first WAL segment file that you need to have to make use of the backup. For example, if the starting WAL file is `0000000100001234000055CD` the backup history file will be named something like `0000000100001234000055CD.007C9330.backup`. (The second part of the file name stands for an exact position within the WAL file, and can ordinarily be ignored.) Once you have safely archived the file system backup and the WAL segment files used during the backup (as specified in the backup history file), all archived WAL segments with names numerically less are no longer needed to recover the file system backup and can be deleted. However, you should consider keeping several backup sets to be absolutely certain that you can recover your data.

The backup history file is just a small text file. It contains the label string you gave to `pg_start_backup`, as well as the starting and ending times and WAL segments of the backup. If you used the label to identify where the associated dump file is kept, then the archived history file is enough to tell you which dump file to restore, should you need to do so.

Since you have to keep around all the archived WAL files back to your last base backup, the interval between base backups should usually be chosen based on how much storage you want to expend on archived WAL files. You should also consider how long you are prepared to spend recovering, if recovery

should be necessary — the system will have to replay all those WAL segments, and that could take awhile if it has been a long time since the last base backup.

It's also worth noting that the `pg_start_backup` function makes a file named `backup_label` in the database cluster directory, which is then removed again by `pg_stop_backup`. This file will of course be archived as a part of your backup dump file. The backup label file includes the label string you gave to `pg_start_backup`, as well as the time at which `pg_start_backup` was run, and the name of the starting WAL file. In case of confusion it will therefore be possible to look inside a backup dump file and determine exactly which backup session the dump file came from.

It is also possible to make a backup dump while the server is stopped. In this case, you obviously cannot use `pg_start_backup` or `pg_stop_backup`, and you will therefore be left to your own devices to keep track of which backup dump is which and how far back the associated WAL files go. It is generally better to follow the continuous archiving procedure above.

### 24.3.3. Recovering using a Continuous Archive Backup

Okay, the worst has happened and you need to recover from your backup. Here is the procedure:

1. Stop the server, if it's running.
2. If you have the space to do so, copy the whole cluster data directory and any tablespaces to a temporary location in case you need them later. Note that this precaution will require that you have enough free space on your system to hold two copies of your existing database. If you do not have enough space, you need at the least to copy the contents of the `pg_xlog` subdirectory of the cluster data directory, as it might contain logs which were not archived before the system went down.
3. Clean out all existing files and subdirectories under the cluster data directory and under the root directories of any tablespaces you are using.
4. Restore the database files from your backup dump. Be careful that they are restored with the right ownership (the database system user, not `root`!) and with the right permissions. If you are using tablespaces, you should verify that the symbolic links in `pg_tblspc/` were correctly restored.
5. Remove any files present in `pg_xlog/`; these came from the backup dump and are therefore probably obsolete rather than current. If you didn't archive `pg_xlog/` at all, then recreate it, being careful to ensure that you re-establish it as a symbolic link if you had it set up that way before. Be sure to recreate the subdirectory `pg_xlog/archive_status/` as well.
6. If you had unarchived WAL segment files that you saved in step 2, copy them into `pg_xlog/`. (It is best to copy them, not move them, so that you still have the unmodified files if a problem occurs and you have to start over.)
7. Create a recovery command file `recovery.conf` in the cluster data directory (see Recovery Settings). You might also want to temporarily modify `pg_hba.conf` to prevent ordinary users from connecting until you are sure the recovery has worked.
8. Start the server. The server will go into recovery mode and proceed to read through the archived WAL files it needs. Should the recovery be terminated because of an external error, the server can simply be restarted and it will continue recovery. Upon completion of the recovery process, the server will rename `recovery.conf` to `recovery.done` (to prevent accidentally re-entering recovery mode in case of a crash later) and then commence normal database operations.

9. Inspect the contents of the database to ensure you have recovered to where you want to be. If not, return to step 1. If all is well, let in your users by restoring `pg_hba.conf` to normal.

The key part of all this is to set up a recovery command file that describes how you want to recover and how far the recovery should run. You can use `recovery.conf.sample` (normally installed in the installation `share/` directory) as a prototype. The one thing that you absolutely must specify in `recovery.conf` is the `restore_command`, which tells PostgreSQL how to get back archived WAL file segments. Like the `archive_command`, this is a shell command string. It can contain `%f`, which is replaced by the name of the desired log file, and `%p`, which is replaced by the path name to copy the log file to. (The path name is relative to the current working directory, i.e., the cluster's data directory.) Write `%%` if you need to embed an actual `%` character in the command. The simplest useful command is something like:

```
restore_command = 'cp /mnt/server/archivedir/%f %p'
```

which will copy previously archived WAL segments from the directory `/mnt/server/archivedir`. You could of course use something much more complicated, perhaps even a shell script that requests the operator to mount an appropriate tape.

It is important that the command return nonzero exit status on failure. The command *will* be asked for log files that are not present in the archive; it must return nonzero when so asked. This is not an error condition. Be aware also that the base name of the `%p` path will be different from `%f`; do not expect them to be interchangeable.

WAL segments that cannot be found in the archive will be sought in `pg_xlog/`; this allows use of recent un-archived segments. However segments that are available from the archive will be used in preference to files in `pg_xlog/`. The system will not overwrite the existing contents of `pg_xlog/` when retrieving archived files.

Normally, recovery will proceed through all available WAL segments, thereby restoring the database to the current point in time (or as close as we can get given the available WAL segments). So a normal recovery will end with a “file not found” message, the exact text of the error message depending upon your choice of `restore_command`. You may also see an error message at the start of recovery for a file named something like `00000001.history`. This is also normal and does not indicate a problem in simple recovery situations. See Section 24.3.4 for discussion.

If you want to recover to some previous point in time (say, right before the junior DBA dropped your main transaction table), just specify the required stopping point in `recovery.conf`. You can specify the stop point, known as the “recovery target”, either by date/time or by completion of a specific transaction ID. As of this writing only the date/time option is very usable, since there are no tools to help you identify with any accuracy which transaction ID to use.

**Note:** The stop point must be after the ending time of the base backup, i.e., the time of `pg_stop_backup`. You cannot use a base backup to recover to a time when that backup was still going on. (To recover to such a time, you must go back to your previous base backup and roll forward from there.)

If recovery finds a corruption in the WAL data then recovery will complete at that point and the server will not start. In such a case the recovery process could be re-run from the beginning, specifying a “recovery target” before the point of corruption so that recovery can complete normally. If recovery fails for an

external reason, such as a system crash or if the WAL archive has become inaccessible, then the recovery can simply be restarted and it will restart almost from where it failed. Recovery restart works much like checkpointing in normal operation: the server periodically forces all its state to disk, and then updates the `pg_control` file to indicate that the already-processed WAL data need not be scanned again.

### 24.3.3.1. Recovery Settings

These settings can only be made in the `recovery.conf` file, and apply only for the duration of the recovery. They must be reset for any subsequent recovery you wish to perform. They cannot be changed once recovery has begun.

`restore_command(string)`

The shell command to execute to retrieve an archived segment of the WAL file series. This parameter is required. Any `%f` in the string is replaced by the name of the file to retrieve from the archive, and any `%p` is replaced by the path name to copy it to on the server. (The path name is relative to the current working directory, i.e., the cluster's data directory.) Any `%r` is replaced by the name of the file containing the last valid restart point. That is the earliest file that must be kept to allow a restore to be restartable, so this information can be used to truncate the archive to just the minimum required to support restart of the current restore. `%r` would only be used in a warm-standby configuration (see Section 24.4). Write `%%` to embed an actual `%` character in the command.

It is important for the command to return a zero exit status if and only if it succeeds. The command *will* be asked for file names that are not present in the archive; it must return nonzero when so asked. Examples:

```
restore_command = 'cp /mnt/server/archivedir/%f "%p"'
restore_command = 'copy /mnt/server/archivedir/%f "%p"' # Windows
```

`recovery_target_time(timestamp)`

This parameter specifies the time stamp up to which recovery will proceed. At most one of `recovery_target_time` and `recovery_target_xid` can be specified. The default is to recover to the end of the WAL log. The precise stopping point is also influenced by `recovery_target_inclusive`.

`recovery_target_xid(string)`

This parameter specifies the transaction ID up to which recovery will proceed. Keep in mind that while transaction IDs are assigned sequentially at transaction start, transactions can complete in a different numeric order. The transactions that will be recovered are those that committed before (and optionally including) the specified one. At most one of `recovery_target_xid` and `recovery_target_time` can be specified. The default is to recover to the end of the WAL log. The precise stopping point is also influenced by `recovery_target_inclusive`.

`recovery_target_inclusive(boolean)`

Specifies whether we stop just after the specified recovery target (`true`), or just before the recovery target (`false`). Applies to both `recovery_target_time` and `recovery_target_xid`, whichever one is specified for this recovery. This indicates whether transactions having exactly the target commit time or ID, respectively, will be included in the recovery. Default is `true`.

`recovery_target_timeline(string)`

Specifies recovering into a particular timeline. The default is to recover along the same timeline that was current when the base backup was taken. You would only need to set this parameter in complex

re-recovery situations, where you need to return to a state that itself was reached after a point-in-time recovery. See Section 24.3.4 for discussion.

`log_restartpoints` (boolean)

Specifies whether to log each restart point as it occurs. This can be helpful to track the progress of a long recovery. Default is `false`.

### 24.3.4. Timelines

The ability to restore the database to a previous point in time creates some complexities that are akin to science-fiction stories about time travel and parallel universes. In the original history of the database, perhaps you dropped a critical table at 5:15PM on Tuesday evening, but didn't realize your mistake until Wednesday noon. Unfazed, you get out your backup, restore to the point-in-time 5:14PM Tuesday evening, and are up and running. In *this* history of the database universe, you never dropped the table at all. But suppose you later realize this wasn't such a great idea after all, and would like to return to sometime Wednesday morning in the original history. You won't be able to if, while your database was up-and-running, it overwrote some of the sequence of WAL segment files that led up to the time you now wish you could get back to. So you really want to distinguish the series of WAL records generated after you've done a point-in-time recovery from those that were generated in the original database history.

To deal with these problems, PostgreSQL has a notion of *timelines*. Whenever an archive recovery is completed, a new timeline is created to identify the series of WAL records generated after that recovery. The timeline ID number is part of WAL segment file names, and so a new timeline does not overwrite the WAL data generated by previous timelines. It is in fact possible to archive many different timelines. While that might seem like a useless feature, it's often a lifesaver. Consider the situation where you aren't quite sure what point-in-time to recover to, and so have to do several point-in-time recoveries by trial and error until you find the best place to branch off from the old history. Without timelines this process would soon generate an unmanageable mess. With timelines, you can recover to *any* prior state, including states in timeline branches that you later abandoned.

Each time a new timeline is created, PostgreSQL creates a "timeline history" file that shows which timeline it branched off from and when. These history files are necessary to allow the system to pick the right WAL segment files when recovering from an archive that contains multiple timelines. Therefore, they are archived into the WAL archive area just like WAL segment files. The history files are just small text files, so it's cheap and appropriate to keep them around indefinitely (unlike the segment files which are large). You can, if you like, add comments to a history file to make your own notes about how and why this particular timeline came to be. Such comments will be especially valuable when you have a thicket of different timelines as a result of experimentation.

The default behavior of recovery is to recover along the same timeline that was current when the base backup was taken. If you want to recover into some child timeline (that is, you want to return to some state that was itself generated after a recovery attempt), you need to specify the target timeline ID in `recovery.conf`. You cannot recover into timelines that branched off earlier than the base backup.

### 24.3.5. Tips and Examples

Some tips for configuring continuous archiving are given here.

### 24.3.5.1. Standalone hot backups

It is possible to use PostgreSQL's backup facilities to produce standalone hot backups. These are backups that cannot be used for point-in-time recovery, yet are typically much faster to backup and restore than `pg_dump` dumps. (They are also much larger than `pg_dump` dumps, so in some cases the speed advantage could be negated.)

To prepare for standalone hot backups, set `archive_mode` to on, and set up an `archive_command` that performs archiving only when a “switch file” exists. For example:

```
archive_command = 'test ! -f /var/lib/pgsql/backup_in_progress || cp -i %p /var/lib/pgsql/a
```

This command will perform archiving when `/var/lib/pgsql/backup_in_progress` exists, and otherwise silently return zero exit status (allowing PostgreSQL to recycle the unwanted WAL file).

With this preparation, a backup can be taken using a script like the following:

```
touch /var/lib/pgsql/backup_in_progress
psql -c "select pg_start_backup('hot_backup');"
tar -cf /var/lib/pgsql/backup.tar /var/lib/pgsql/data/
psql -c "select pg_stop_backup();"
sleep 20
rm /var/lib/pgsql/backup_in_progress
tar -rf /var/lib/pgsql/backup.tar /var/lib/pgsql/archive/
```

The switch file `/var/lib/pgsql/backup_in_progress` is created first, enabling archiving of completed WAL files to occur. After the backup the switch file is removed. Archived WAL files are then added to the backup so that both base backup and all required WAL files are part of the same tar file.

### 24.3.5.2. archive\_command scripts

Many people choose to use scripts to define their `archive_command`, so that their `postgresql.conf` entry looks very simple:

```
archive_command = 'local_backup_script.sh'
```

Using a separate script file is advisable any time you want to use more than a single command in the archiving process. This allows all complexity to be managed within the script, which can be written in a popular scripting language such as bash or perl. Any messages written to `stderr` from the script will appear in the database server log, allowing complex configurations to be diagnosed easily if they fail.

Examples of requirements that might be solved within a script include:

- Copying data to secure off-site data storage
- Batching WAL files so that they are transferred every three hours, rather than one at a time
- Interfacing with other backup and recovery software
- Interfacing with monitoring software to report errors

### 24.3.6. Caveats

At this writing, there are several limitations of the continuous archiving technique. These will probably be fixed in future releases:

- Operations on hash indexes are not presently WAL-logged, so replay will not update these indexes. The recommended workaround is to manually *REINDEX* each such index after completing a recovery operation.
- If a *CREATE DATABASE* command is executed while a base backup is being taken, and then the template database that the *CREATE DATABASE* copied is modified while the base backup is still in progress, it is possible that recovery will cause those modifications to be propagated into the created database as well. This is of course undesirable. To avoid this risk, it is best not to modify any template databases while taking a base backup.
- *CREATE TABLESPACE* commands are WAL-logged with the literal absolute path, and will therefore be replayed as tablespace creations with the same absolute path. This might be undesirable if the log is being replayed on a different machine. It can be dangerous even if the log is being replayed on the same machine, but into a new data directory: the replay will still overwrite the contents of the original tablespace. To avoid potential gotchas of this sort, the best practice is to take a new base backup after creating or dropping tablespaces.

It should also be noted that the default WAL format is fairly bulky since it includes many disk page snapshots. These page snapshots are designed to support crash recovery, since we might need to fix partially-written disk pages. Depending on your system hardware and software, the risk of partial writes might be small enough to ignore, in which case you can significantly reduce the total volume of archived logs by turning off page snapshots using the *full\_page\_writes* parameter. (Read the notes and warnings in Chapter 28 before you do so.) Turning off page snapshots does not prevent use of the logs for PITR operations. An area for future development is to compress archived WAL data by removing unnecessary page copies even when *full\_page\_writes* is on. In the meantime, administrators might wish to reduce the number of page snapshots included in WAL by increasing the checkpoint interval parameters as much as feasible.

## 24.4. Warm Standby Servers for High Availability

Continuous archiving can be used to create a *high availability* (HA) cluster configuration with one or more *standby servers* ready to take over operations if the primary server fails. This capability is widely referred to as *warm standby* or *log shipping*.

The primary and standby server work together to provide this capability, though the servers are only loosely coupled. The primary server operates in continuous archiving mode, while each standby server operates in continuous recovery mode, reading the WAL files from the primary. No changes to the database tables are required to enable this capability, so it offers low administration overhead in comparison with some other replication approaches. This configuration also has relatively low performance impact on the primary server.

Directly moving WAL records from one database server to another is typically described as log shipping. PostgreSQL implements file-based log shipping, which means that WAL records are transferred one file

(WAL segment) at a time. WAL files (16MB) can be shipped easily and cheaply over any distance, whether it be to an adjacent system, another system on the same site or another system on the far side of the globe. The bandwidth required for this technique varies according to the transaction rate of the primary server. Record-based log shipping is also possible with custom-developed procedures, as discussed in Section 24.4.4.

It should be noted that the log shipping is asynchronous, i.e. the WAL records are shipped after transaction commit. As a result there is a window for data loss should the primary server suffer a catastrophic failure: transactions not yet shipped will be lost. The length of the window of data loss can be limited by use of the `archive_timeout` parameter, which can be set as low as a few seconds if required. However such low settings will substantially increase the bandwidth requirements for file shipping. If you need a window of less than a minute or so, it's probably better to look into record-based log shipping.

The standby server is not available for access, since it is continually performing recovery processing. Recovery performance is sufficiently good that the standby will typically be only moments away from full availability once it has been activated. As a result, we refer to this capability as a warm standby configuration that offers high availability. Restoring a server from an archived base backup and rollforward will take considerably longer, so that technique only offers a solution for disaster recovery, not high availability.

## 24.4.1. Planning

It is usually wise to create the primary and standby servers so that they are as similar as possible, at least from the perspective of the database server. In particular, the path names associated with tablespaces will be passed across as-is, so both primary and standby servers must have the same mount paths for tablespaces if that feature is used. Keep in mind that if `CREATE TABLESPACE` is executed on the primary, any new mount point needed for it must be created on both the primary and all standby servers before the command is executed. Hardware need not be exactly the same, but experience shows that maintaining two identical systems is easier than maintaining two dissimilar ones over the lifetime of the application and system. In any case the hardware architecture must be the same — shipping from, say, a 32-bit to a 64-bit system will not work.

In general, log shipping between servers running different major PostgreSQL release levels will not be possible. It is the policy of the PostgreSQL Global Development Group not to make changes to disk formats during minor release upgrades, so it is likely that running different minor release levels on primary and standby servers will work successfully. However, no formal support for that is offered and you are advised to keep primary and standby servers at the same release level as much as possible. When updating to a new minor release, the safest policy is to update the standby servers first — a new minor release is more likely to be able to read WAL files from a previous minor release than vice versa.

There is no special mode required to enable a standby server. The operations that occur on both primary and standby servers are entirely normal continuous archiving and recovery tasks. The only point of contact between the two database servers is the archive of WAL files that both share: primary writing to the archive, standby reading from the archive. Care must be taken to ensure that WAL archives for separate primary servers do not become mixed together or confused. The archive need not be large, if it is only required for the standby operation.

The magic that makes the two loosely coupled servers work together is simply a `restore_command` used on the standby that waits for the next WAL file to become available from the primary. The `restore_command` is specified in the `recovery.conf` file on the standby server. Normal recovery

processing would request a file from the WAL archive, reporting failure if the file was unavailable. For standby processing it is normal for the next file to be unavailable, so we must be patient and wait for it to appear. A waiting `restore_command` can be written as a custom script that loops after polling for the existence of the next WAL file. There must also be some way to trigger failover, which should interrupt the `restore_command`, break the loop and return a file-not-found error to the standby server. This ends recovery and the standby will then come up as a normal server.

Pseudocode for a suitable `restore_command` is:

```
triggered = false;
while (!NextWALFileReady() && !triggered)
{
    sleep(100000L);          /* wait for ~0.1 sec */
    if (CheckForExternalTrigger())
        triggered = true;
}
if (!triggered)
    CopyWALFileForRecovery();
```

A working example of a waiting `restore_command` is provided as a contrib module named `pg_standby`. This example can be extended as needed to support specific configurations or environments.

PostgreSQL does not provide the system software required to identify a failure on the primary and notify the standby system and then the standby database server. Many such tools exist and are well integrated with other aspects required for successful failover, such as IP address migration.

The means for triggering failover is an important part of planning and design. The `restore_command` is executed in full once for each WAL file. The process running the `restore_command` is therefore created and dies for each file, so there is no daemon or server process and so we cannot use signals and a signal handler. A more permanent notification is required to trigger the failover. It is possible to use a simple timeout facility, especially if used in conjunction with a known `archive_timeout` setting on the primary. This is somewhat error prone since a network problem or busy primary server might be sufficient to initiate failover. A notification mechanism such as the explicit creation of a trigger file is less error prone, if this can be arranged.

The size of the WAL archive can be minimized by using the `%r` option of the `restore_command`. This option specifies the last archive file name that needs to be kept to allow the recovery to restart correctly. This can be used to truncate the archive once files are no longer required, if the archive is writable from the standby server.

## 24.4.2. Implementation

The short procedure for configuring a standby server is as follows. For full details of each step, refer to previous sections as noted.

1. Set up primary and standby systems as near identically as possible, including two identical copies of PostgreSQL at the same release level.

2. Set up continuous archiving from the primary to a WAL archive located in a directory on the standby server. Ensure that `archive_mode`, `archive_command` and `archive_timeout` are set appropriately on the primary (see Section 24.3.1).
3. Make a base backup of the primary server (see Section 24.3.2), and load this data onto the standby.
4. Begin recovery on the standby server from the local WAL archive, using a `recovery.conf` that specifies a `restore_command` that waits as described previously (see Section 24.3.3).

Recovery treats the WAL archive as read-only, so once a WAL file has been copied to the standby system it can be copied to tape at the same time as it is being read by the standby database server. Thus, running a standby server for high availability can be performed at the same time as files are stored for longer term disaster recovery purposes.

For testing purposes, it is possible to run both primary and standby servers on the same system. This does not provide any worthwhile improvement in server robustness, nor would it be described as HA.

### 24.4.3. Failover

If the primary server fails then the standby server should begin failover procedures.

If the standby server fails then no failover need take place. If the standby server can be restarted, even some time later, then the recovery process can also be immediately restarted, taking advantage of restartable recovery. If the standby server cannot be restarted, then a full new standby server instance should be created.

If the primary server fails and then immediately restarts, you must have a mechanism for informing it that it is no longer the primary. This is sometimes known as STONITH (Shoot the Other Node In The Head), which is necessary to avoid situations where both systems think they are the primary, which will lead to confusion and ultimately data loss.

Many failover systems use just two systems, the primary and the standby, connected by some kind of heart-beat mechanism to continually verify the connectivity between the two and the viability of the primary. It is also possible to use a third system (called a witness server) to prevent some cases of inappropriate failover, but the additional complexity might not be worthwhile unless it is set up with sufficient care and rigorous testing.

Once failover to the standby occurs, we have only a single server in operation. This is known as a de-generate state. The former standby is now the primary, but the former primary is down and might stay down. To return to normal operation we must fully recreate a standby server, either on the former primary system when it comes up, or on a third, possibly new, system. Once complete the primary and standby can be considered to have switched roles. Some people choose to use a third server to provide backup to the new primary until the new standby server is recreated, though clearly this complicates the system configuration and operational processes.

So, switching from primary to standby server can be fast but requires some time to re-prepare the failover cluster. Regular switching from primary to standby is useful, since it allows regular downtime on each system for maintenance. This also serves as a test of the failover mechanism to ensure that it will really work when you need it. Written administration procedures are advised.

### 24.4.4. Record-based Log Shipping

PostgreSQL directly supports file-based log shipping as described above. It is also possible to implement record-based log shipping, though this requires custom development.

An external program can call the `pg_xlogfile_name_offset()` function (see Section 9.23) to find out the file name and the exact byte offset within it of the current end of WAL. It can then access the WAL file directly and copy the data from the last known end of WAL through the current end over to the standby server(s). With this approach, the window for data loss is the polling cycle time of the copying program, which can be very small, but there is no wasted bandwidth from forcing partially-used segment files to be archived. Note that the standby servers' `restore_command` scripts still deal in whole WAL files, so the incrementally copied data is not ordinarily made available to the standby servers. It is of use only when the primary dies — then the last partial WAL file is fed to the standby before allowing it to come up. So correct implementation of this process requires cooperation of the `restore_command` script with the data copying program.

### 24.4.5. Incrementally Updated Backups

In a warm standby configuration, it is possible to offload the expense of taking periodic base backups from the primary server; instead base backups can be made by backing up a standby server's files. This concept is generally known as incrementally updated backups, log change accumulation, or more simply, change accumulation.

If we take a backup of the standby server's data directory while it is processing logs shipped from the primary, we will be able to reload that data and restart the standby's recovery process from the last restart point. We no longer need to keep WAL files from before the restart point. If we need to recover, it will be faster to recover from the incrementally updated backup than from the original base backup.

Since the standby server is not “live”, it is not possible to use `pg_start_backup()` and `pg_stop_backup()` to manage the backup process; it will be up to you to determine how far back you need to keep WAL segment files to have a recoverable backup. You can do this by running `pg_controldata` on the standby server to inspect the control file and determine the current checkpoint WAL location, or by using the `log_restartpoints` option to print values to the server log.

## 24.5. Migration Between Releases

This section discusses how to migrate your database data from one PostgreSQL release to a newer one. The software installation procedure *per se* is not the subject of this section; those details are in Chapter 15.

As a general rule, the internal data storage format is subject to change between major releases of PostgreSQL (where the number after the first dot changes). This does not apply to different minor releases under the same major release (where the number after the second dot changes); these always have compatible storage formats. For example, releases 8.1.1, 8.2.3, and 8.3 are not compatible, whereas 8.2.3 and 8.2.4 are. When you update between compatible versions, you can simply replace the executables and reuse the data directory on disk. Otherwise you need to back up your data and restore it on the new server. This has to be done using `pg_dump`; file system level backup methods obviously won't work. There are

checks in place that prevent you from using a data directory with an incompatible version of PostgreSQL, so no great harm can be done by trying to start the wrong server version on a data directory.

It is recommended that you use the `pg_dump` and `pg_dumpall` programs from the newer version of PostgreSQL, to take advantage of any enhancements that might have been made in these programs. Current releases of the dump programs can read data from any server version back to 7.0.

The least downtime can be achieved by installing the new server in a different directory and running both the old and the new servers in parallel, on different ports. Then you can use something like:

```
pg_dumpall -p 5432 | psql -d postgres -p 6543
```

to transfer your data. Or use an intermediate file if you want. Then you can shut down the old server and start the new server at the port the old one was running at. You should make sure that the old database is not updated after you begin to run `pg_dumpall`, otherwise you will lose that data. See Chapter 21 for information on how to prohibit access.

It is also possible to use replication methods, such as Slony, to create a slave server with the updated version of PostgreSQL. The slave can be on the same computer or a different computer. Once it has synced up with the master server (running the older version of PostgreSQL), you can switch masters and make the slave the master and shut down the older database instance. Such a switch-over results in only several seconds of downtime for an upgrade.

In practice you probably want to test your client applications on the new setup before switching over completely. This is another reason for setting up concurrent installations of old and new versions.

If you cannot or do not want to run two servers in parallel, you can do the backup step before installing the new version, bring down the server, move the old version out of the way, install the new version, start the new server, and restore the data. For example:

```
pg_dumpall > backup
pg_ctl stop
mv /usr/local/pgsql /usr/local/pgsql.old
cd ~/postgresql-8.3.1
gmake install
initdb -D /usr/local/pgsql/data
postgres -D /usr/local/pgsql/data
psql -f backup postgres
```

See Chapter 17 about ways to start and stop the server and other details. The installation instructions will advise you of strategic places to perform these steps.

**Note:** When you “move the old installation out of the way” it might no longer be perfectly usable. Some of the executable programs contain absolute paths to various installed programs and data files. This is usually not a big problem, but if you plan on using two installations in parallel for a while you should assign them different installation directories at build time. (This problem is rectified in PostgreSQL 8.0 and later, so long as you move all subdirectories containing installed files together; for example if `/usr/local/postgres/bin/` goes to `/usr/local/postgres.old/bin/`, then `/usr/local/postgres/share/` must go to `/usr/local/postgres.old/share/`. In pre-8.0 releases moving an installation like this will not work.)

# Chapter 25. High Availability, Load Balancing, and Replication

Database servers can work together to allow a second server to take over quickly if the primary server fails (high availability), or to allow several computers to serve the same data (load balancing). Ideally, database servers could work together seamlessly. Web servers serving static web pages can be combined quite easily by merely load-balancing web requests to multiple machines. In fact, read-only database servers can be combined relatively easily too. Unfortunately, most database servers have a read/write mix of requests, and read/write servers are much harder to combine. This is because though read-only data needs to be placed on each server only once, a write to any server has to be propagated to all servers so that future read requests to those servers return consistent results.

This synchronization problem is the fundamental difficulty for servers working together. Because there is no single solution that eliminates the impact of the sync problem for all use cases, there are multiple solutions. Each solution addresses this problem in a different way, and minimizes its impact for a specific workload.

Some solutions deal with synchronization by allowing only one server to modify the data. Servers that can modify data are called read/write or "master" servers. Servers that can reply to read-only queries are called "slave" servers. Servers that cannot be accessed until they are changed to master servers are called "standby" servers.

Some solutions are synchronous, meaning that a data-modifying transaction is not considered committed until all servers have committed the transaction. This guarantees that a failover will not lose any data and that all load-balanced servers will return consistent results no matter which server is queried. In contrast, asynchronous solutions allow some delay between the time of a commit and its propagation to the other servers, opening the possibility that some transactions might be lost in the switch to a backup server, and that load balanced servers might return slightly stale results. Asynchronous communication is used when synchronous would be too slow.

Solutions can also be categorized by their granularity. Some solutions can deal only with an entire database server, while others allow control at the per-table or per-database level.

Performance must be considered in any choice. There is usually a trade-off between functionality and performance. For example, a full synchronous solution over a slow network might cut performance by more than half, while an asynchronous one might have a minimal performance impact.

The remainder of this section outlines various failover, replication, and load balancing solutions. A glossary<sup>1</sup> is also available.

## Shared Disk Failover

Shared disk failover avoids synchronization overhead by having only one copy of the database. It uses a single disk array that is shared by multiple servers. If the main database server fails, the standby server is able to mount and start the database as though it was recovering from a database crash. This allows rapid failover with no data loss.

Shared hardware functionality is common in network storage devices. Using a network file system is also possible, though care must be taken that the file system has full POSIX behavior (see Section 17.2.1). One significant limitation of this method is that if the shared disk array fails or becomes

---

1. <http://www.postgres-r.org/documentation/terms>

corrupt, the primary and standby servers are both nonfunctional. Another issue is that the standby server should never access the shared storage while the primary server is running.

#### File System (Block-Device) Replication

A modified version of shared hardware functionality is file system replication, where all changes to a file system are mirrored to a file system residing on another computer. The only restriction is that the mirroring must be done in a way that ensures the standby server has a consistent copy of the file system — specifically, writes to the standby must be done in the same order as those on the master. DRBD is a popular file system replication solution for Linux.

#### Warm Standby Using Point-In-Time Recovery (PITR)

A warm standby server (see Section 24.4) can be kept current by reading a stream of write-ahead log (WAL) records. If the main server fails, the warm standby contains almost all of the data of the main server, and can be quickly made the new master database server. This is asynchronous and can only be done for the entire database server.

#### Master-Slave Replication

A master-slave replication setup sends all data modification queries to the master server. The master server asynchronously sends data changes to the slave server. The slave can answer read-only queries while the master server is running. The slave server is ideal for data warehouse queries.

Slony-I is an example of this type of replication, with per-table granularity, and support for multiple slaves. Because it updates the slave server asynchronously (in batches), there is possible data loss during fail over.

#### Statement-Based Replication Middleware

With statement-based replication middleware, a program intercepts every SQL query and sends it to one or all servers. Each server operates independently. Read-write queries are sent to all servers, while read-only queries can be sent to just one server, allowing the read workload to be distributed.

If queries are simply broadcast unmodified, functions like `random()`, `CURRENT_TIMESTAMP`, and sequences would have different values on different servers. This is because each server operates independently, and because SQL queries are broadcast (and not actual modified rows). If this is unacceptable, either the middleware or the application must query such values from a single server and then use those values in write queries. Also, care must be taken that all transactions either commit or abort on all servers, perhaps using two-phase commit (*PREPARE TRANSACTION* and *COMMIT PREPARED*). Pgpool-II and Sequoia are examples of this type of replication.

#### Asynchronous Multimaster Replication

For servers that are not regularly connected, like laptops or remote servers, keeping data consistent among servers is a challenge. Using asynchronous multimaster replication, each server works independently, and periodically communicates with the other servers to identify conflicting transactions. The conflicts can be resolved by users or conflict resolution rules.

#### Synchronous Multimaster Replication

In synchronous multimaster replication, each server can accept write requests, and modified data is transmitted from the original server to every other server before each transaction commits. Heavy write activity can cause excessive locking, leading to poor performance. In fact, write performance is often worse than that of a single server. Read requests can be sent to any server. Some implementations use shared disk to reduce the communication overhead. Synchronous multimaster replication is

best for mostly read workloads, though its big advantage is that any server can accept write requests — there is no need to partition workloads between master and slave servers, and because the data changes are sent from one server to another, there is no problem with non-deterministic functions like `random()`.

PostgreSQL does not offer this type of replication, though PostgreSQL two-phase commit (*PREPARE TRANSACTION* and *COMMIT PREPARED*) can be used to implement this in application code or middleware.

#### Commercial Solutions

Because PostgreSQL is open source and easily extended, a number of companies have taken PostgreSQL and created commercial closed-source solutions with unique failover, replication, and load balancing capabilities.

Table 25-1 summarizes the capabilities of the various solutions listed above.

**Table 25-1. High Availability, Load Balancing, and Replication Feature Matrix**

<b>Feature</b>	<b>Shared Disk Failover</b>	<b>File System Replication</b>	<b>Warm Standby Using PITR</b>	<b>Master-Slave Replication</b>	<b>Statement-Based Replication Middleware</b>	<b>Asynchronous Multi-master Replication</b>	<b>Synchronous Multi-master Replication</b>
No special hardware required		•	•	•	•	•	•
Allows multiple master servers					•	•	•
No master server overhead	•		•		•		
No waiting for multiple servers	•		•	•		•	
Master failure will never lose data	•	•			•		•
Slaves accept read-only queries				•	•	•	•

Feature	Shared Disk Failover	File System Replication	Warm Standby Using PITR	Master-Slave Replication	Statement-Based Replication Middleware	Asynchronous Multi-master Replication	Synchronous Multi-master Replication
Per-table granularity				•		•	•
No conflict resolution necessary	•	•	•	•			•
Communication Method	shared disk	disk blocks	WAL	table rows	SQL	table rows	table rows and row locks

There are a few solutions that do not fit into the above categories:

#### Data Partitioning

Data partitioning splits tables into data sets. Each set can be modified by only one server. For example, data can be partitioned by offices, e.g. London and Paris, with a server in each office. If queries combining London and Paris data are necessary, an application can query both servers, or master/slave replication can be used to keep a read-only copy of the other office's data on each server.

#### Multiple-Server Parallel Query Execution

Many of the above solutions allow multiple servers to handle multiple queries, but none allow a single query to use multiple servers to complete faster. This solution allows multiple servers to work concurrently on a single query. It is usually accomplished by splitting the data among servers and having each server execute its part of the query and return results to a central server where they are combined and returned to the user. Pgpool-II has this capability. Also, this can be implemented using the PL/Proxy toolset.

# Chapter 26. Monitoring Database Activity

A database administrator frequently wonders, “What is the system doing right now?” This chapter discusses how to find that out.

Several tools are available for monitoring database activity and analyzing performance. Most of this chapter is devoted to describing PostgreSQL’s statistics collector, but one should not neglect regular Unix monitoring programs such as `ps`, `top`, `iostat`, and `vmstat`. Also, once one has identified a poorly-performing query, further investigation might be needed using PostgreSQL’s `EXPLAIN` command. Section 14.1 discusses `EXPLAIN` and other methods for understanding the behavior of an individual query.

## 26.1. Standard Unix Tools

On most platforms, PostgreSQL modifies its command title as reported by `ps`, so that individual server processes can readily be identified. A sample display is

```
$ ps auxww | grep ^postgres
postgres  960  0.0  1.1  6104 1480 pts/1      SN   13:17   0:00 postgres -i
postgres  963  0.0  1.1  7084 1472 pts/1      SN   13:17   0:00 postgres: writer process
postgres  965  0.0  1.1  6152 1512 pts/1      SN   13:17   0:00 postgres: stats collector pr
postgres  998  0.0  2.3  6532 2992 pts/1      SN   13:18   0:00 postgres: tgl runbug 127.0.0
postgres 1003  0.0  2.4  6532 3128 pts/1      SN   13:19   0:00 postgres: tgl regression [lo
postgres 1016  0.1  2.4  6532 3080 pts/1      SN   13:19   0:00 postgres: tgl regression [lo
```

(The appropriate invocation of `ps` varies across different platforms, as do the details of what is shown. This example is from a recent Linux system.) The first process listed here is the master server process. The command arguments shown for it are the same ones given when it was launched. The next two processes are background worker processes automatically launched by the master process. (The “stats collector” process will not be present if you have set the system not to start the statistics collector.) Each of the remaining processes is a server process handling one client connection. Each such process sets its command line display in the form

```
postgres: user database host activity
```

The user, database, and connection source host items remain the same for the life of the client connection, but the activity indicator changes. The activity can be `idle` (i.e., waiting for a client command), `idle in transaction` (waiting for client inside a `BEGIN` block), or a command type name such as `SELECT`. Also, `waiting` is attached if the server process is presently waiting on a lock held by another server process. In the above example we can infer that process 1003 is waiting for process 1016 to complete its transaction and thereby release some lock or other.

If you have turned off `update_process_title` then the activity indicator is not updated; the process title is set only once when a new process is launched. On some platforms this saves a useful amount of per-command overhead, on others it’s insignificant.

**Tip:** Solaris requires special handling. You must use `/usr/ucb/ps`, rather than `/bin/ps`. You also must use two `w` flags, not just one. In addition, your original invocation of the `postgres` command must have a shorter `ps` status display than that provided by each server process. If you fail to do all three things, the `ps` output for each server process will be the original `postgres` command line.

## 26.2. The Statistics Collector

PostgreSQL's *statistics collector* is a subsystem that supports collection and reporting of information about server activity. Presently, the collector can count accesses to tables and indexes in both disk-block and individual-row terms. It also tracks total numbers of rows in each table, and the last vacuum and analyze times for each table.

PostgreSQL also supports determining the exact command currently being executed by other server processes. This is an independent facility that does not depend on the collector process.

### 26.2.1. Statistics Collection Configuration

Since collection of statistics adds some overhead to query execution, the system can be configured to collect or not collect information. This is controlled by configuration parameters that are normally set in `postgresql.conf`. (See Chapter 18 for details about setting configuration parameters.)

The parameter `track_counts` controls whether information is actually sent to the collector process and thus determines whether any run-time overhead occurs for event counting.

The parameter `track_activities` enables monitoring of the current command being executed by any server process.

Normally these parameters are set in `postgresql.conf` so that they apply to all server processes, but it is possible to turn them on or off in individual sessions using the *SET* command. (To prevent ordinary users from hiding their activity from the administrator, only superusers are allowed to change these parameters with *SET*.)

### 26.2.2. Viewing Collected Statistics

Several predefined views, listed in Table 26-1, are available to show the results of statistics collection. Alternatively, one can build custom views using the underlying statistics functions.

When using the statistics to monitor current activity, it is important to realize that the information does not update instantaneously. Each individual server process transmits new statistical counts to the collector just before going idle; so a query or transaction still in progress does not affect the displayed totals. Also, the collector itself emits a new report at most once per `PGSTAT_STAT_INTERVAL` milliseconds (500 unless altered while building the server). So the displayed information lags behind actual activity. However, current-query information collected by `track_activities` is always up-to-date.

Another important point is that when a server process is asked to display any of these statistics, it first fetches the most recent report emitted by the collector process and then continues to use this snapshot for all statistical views and functions until the end of its current transaction. So the statistics will appear not to change as long as you continue the current transaction. Similarly, information about the current queries of all processes is collected when any such information is first requested within a transaction, and the same information will be displayed throughout the transaction. This is a feature, not a bug, because it allows you to perform several queries on the statistics and correlate the results without worrying that the numbers

are changing underneath you. But if you want to see new results with each query, be sure to do the queries outside any transaction block. Alternatively, you can invoke `pg_stat_clear_snapshot()`, which will discard the current transaction's statistics snapshot (if any). The next use of statistical information will cause a new snapshot to be fetched.

**Table 26-1. Standard Statistics Views**

View Name	Description
<code>pg_stat_activity</code>	One row per server process, showing database OID, database name, process ID, user OID, user name, current query, query's waiting status, time at which the current transaction and current query began execution, time at which the process was started, and client's address and port number. The columns that report data on the current query are available unless the parameter <code>track_activities</code> has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.
<code>pg_stat_bgwriter</code>	One row only, showing cluster-wide statistics from the background writer: number of scheduled checkpoints, requested checkpoints, buffers written by checkpoints and cleaning scans, and the number of times the background writer stopped a cleaning scan because it had written too many buffers. Also includes statistics about the shared buffer pool, including buffers written by backends (that is, not by the background writer) and total buffers allocated.
<code>pg_stat_database</code>	One row per database, showing database OID, database name, number of active server processes connected to that database, number of transactions committed and rolled back in that database, total disk blocks read, total buffer hits (i.e., block read requests avoided by finding the block already in buffer cache), number of rows returned, inserted, updated and deleted.

View Name	Description
<code>pg_stat_all_tables</code>	For each table in the current database (including TOAST tables), the table OID, schema and table name, number of sequential scans initiated, number of live rows fetched by sequential scans, number of index scans initiated (over all indexes belonging to the table), number of live rows fetched by index scans, numbers of row insertions, updates, and deletions, number of row updates that were HOT (i.e., no separate index update), numbers of live and dead rows, the last time the table was vacuumed manually, the last time it was vacuumed by the autovacuum daemon, the last time it was analyzed manually, and the last time it was analyzed by the autovacuum daemon.
<code>pg_stat_sys_tables</code>	Same as <code>pg_stat_all_tables</code> , except that only system tables are shown.
<code>pg_stat_user_tables</code>	Same as <code>pg_stat_all_tables</code> , except that only user tables are shown.
<code>pg_stat_all_indexes</code>	For each index in the current database, the table and index OID, schema, table and index name, number of index scans initiated on that index, number of index entries returned by index scans, and number of live table rows fetched by simple index scans using that index.
<code>pg_stat_sys_indexes</code>	Same as <code>pg_stat_all_indexes</code> , except that only indexes on system tables are shown.
<code>pg_stat_user_indexes</code>	Same as <code>pg_stat_all_indexes</code> , except that only indexes on user tables are shown.
<code>pg_statio_all_tables</code>	For each table in the current database (including TOAST tables), the table OID, schema and table name, number of disk blocks read from that table, number of buffer hits, numbers of disk blocks read and buffer hits in all indexes of that table, numbers of disk blocks read and buffer hits from that table's auxiliary TOAST table (if any), and numbers of disk blocks read and buffer hits for the TOAST table's index.
<code>pg_statio_sys_tables</code>	Same as <code>pg_statio_all_tables</code> , except that only system tables are shown.
<code>pg_statio_user_tables</code>	Same as <code>pg_statio_all_tables</code> , except that only user tables are shown.

View Name	Description
<code>pg_statio_all_indexes</code>	For each index in the current database, the table and index OID, schema, table and index name, numbers of disk blocks read and buffer hits in that index.
<code>pg_statio_sys_indexes</code>	Same as <code>pg_statio_all_indexes</code> , except that only indexes on system tables are shown.
<code>pg_statio_user_indexes</code>	Same as <code>pg_statio_all_indexes</code> , except that only indexes on user tables are shown.
<code>pg_statio_all_sequences</code>	For each sequence object in the current database, the sequence OID, schema and sequence name, numbers of disk blocks read and buffer hits in that sequence.
<code>pg_statio_sys_sequences</code>	Same as <code>pg_statio_all_sequences</code> , except that only system sequences are shown. (Presently, no system sequences are defined, so this view is always empty.)
<code>pg_statio_user_sequences</code>	Same as <code>pg_statio_all_sequences</code> , except that only user sequences are shown.

The per-index statistics are particularly useful to determine which indexes are being used and how effective they are.

Beginning in PostgreSQL 8.1, indexes can be used either directly or via “bitmap scans”. In a bitmap scan the output of several indexes can be combined via AND or OR rules; so it is difficult to associate individual heap row fetches with specific indexes when a bitmap scan is used. Therefore, a bitmap scan increments the `pg_stat_all_indexes.idx_tup_read` count(s) for the index(es) it uses, and it increments the `pg_stat_all_tables.idx_tup_fetch` count for the table, but it does not affect `pg_stat_all_indexes.idx_tup_fetch`.

**Note:** Before PostgreSQL 8.1, the `idx_tup_read` and `idx_tup_fetch` counts were essentially always equal. Now they can be different even without considering bitmap scans, because `idx_tup_read` counts index entries retrieved from the index while `idx_tup_fetch` counts live rows fetched from the table; the latter will be less if any dead or not-yet-committed rows are fetched using the index.

The `pg_statio_` views are primarily useful to determine the effectiveness of the buffer cache. When the number of actual disk reads is much smaller than the number of buffer hits, then the cache is satisfying most read requests without invoking a kernel call. However, these statistics do not give the entire story: due to the way in which PostgreSQL handles disk I/O, data that is not in the PostgreSQL buffer cache might still reside in the kernel’s I/O cache, and might therefore still be fetched without requiring a physical read. Users interested in obtaining more detailed information on PostgreSQL I/O behavior are advised to use the PostgreSQL statistics collector in combination with operating system utilities that allow insight into the kernel’s handling of I/O.

Other ways of looking at the statistics can be set up by writing queries that use the same underlying statistics access functions as these standard views do. These functions are listed in Table 26-2. The per-database access functions take a database OID as argument to identify which database to report on. The

per-table and per-index functions take a table or index OID. (Note that only tables and indexes in the current database can be seen with these functions.) The per-server-process access functions take a server process number, which ranges from one to the number of currently active server processes.

**Table 26-2. Statistics Access Functions**

Function	Return Type	Description
<code>pg_stat_get_db_numbackends(oid)</code>	integer	Number of active server processes for database
<code>pg_stat_get_db_xact_commit(oid)</code>	bigint	Transactions committed in database
<code>pg_stat_get_db_xact_rollback(oid)</code>	bigint	Transactions rolled back in database
<code>pg_stat_get_db_blocks_fetched(oid)</code>	bigint	Number of disk block fetch requests for database
<code>pg_stat_get_db_blocks_hit(oid)</code>	bigint	Number of disk block fetch requests found in cache for database
<code>pg_stat_get_db_tuples_returned(oid)</code>	bigint	Number of tuples returned for database
<code>pg_stat_get_db_tuples_fetched(oid)</code>	bigint	Number of tuples fetched for database
<code>pg_stat_get_db_tuples_inserted(oid)</code>	bigint	Number of tuples inserted in database
<code>pg_stat_get_db_tuples_updated(oid)</code>	bigint	Number of tuples updated in database
<code>pg_stat_get_db_tuples_deleted(oid)</code>	bigint	Number of tuples deleted in database
<code>pg_stat_get_numscans(oid)</code>	bigint	Number of sequential scans done when argument is a table, or number of index scans done when argument is an index
<code>pg_stat_get_tuples_returned(oid)</code>	bigint	Number of rows read by sequential scans when argument is a table, or number of index entries returned when argument is an index
<code>pg_stat_get_tuples_fetched(oid)</code>	bigint	Number of table rows fetched by bitmap scans when argument is a table, or table rows fetched by simple index scans using the index when argument is an index
<code>pg_stat_get_tuples_inserted(oid)</code>	bigint	Number of rows inserted into table

Function	Return Type	Description
<code>pg_stat_get_tuples_updated(oid)</code>	<code>bigint</code>	Number of rows updated in table (includes HOT updates)
<code>pg_stat_get_tuples_deleted(oid)</code>	<code>bigint</code>	Number of rows deleted from table
<code>pg_stat_get_tuples_hot_updated(oid)</code>	<code>bigint</code>	Number of rows HOT-updated in table
<code>pg_stat_get_live_tuples(oid)</code>	<code>bigint</code>	Number of live rows in table
<code>pg_stat_get_dead_tuples(oid)</code>	<code>bigint</code>	Number of dead rows in table
<code>pg_stat_get_blocks_fetched(oid)</code>	<code>bigint</code>	Number of disk block fetch requests for table or index
<code>pg_stat_get_blocks_hit(oid)</code>	<code>bigint</code>	Number of disk block requests found in cache for table or index
<code>pg_stat_get_last_vacuum_time(oid)</code>	<code>timestampz</code>	Time of the last vacuum initiated by the user on this table
<code>pg_stat_get_last_autovacuum_time(oid)</code>	<code>timestampz</code>	Time of the last vacuum initiated by the autovacuum daemon on this table
<code>pg_stat_get_last_analyze_time(oid)</code>	<code>timestampz</code>	Time of the last analyze initiated by the user on this table
<code>pg_stat_get_last_autoanalyze_time(oid)</code>	<code>timestampz</code>	Time of the last analyze initiated by the autovacuum daemon on this table
<code>pg_stat_get_backend_idset()</code>	<code>setof integer</code>	Set of currently active server process numbers (from 1 to the number of active server processes). See usage example in the text
<code>pg_backend_pid()</code>	<code>integer</code>	Process ID of the server process attached to the current session
<code>pg_stat_get_backend_pid(integer)</code>	<code>integer</code>	Process ID of the given server process
<code>pg_stat_get_backend_dbid(integer)</code>	<code>integer</code>	Database ID of the given server process
<code>pg_stat_get_backend_userid(integer)</code>	<code>integer</code>	User ID of the given server process
<code>pg_stat_get_backend_activity(integer)</code>	<code>text</code>	Active command of the given server process, but only if the current user is a superuser or the same user as that of the session being queried (and <code>track_activities</code> is on)

Function	Return Type	Description
<code>pg_stat_get_backend_waiting(integer)</code>	<code>boolean</code>	True if the given server process is waiting for a lock, but only if the current user is a superuser or the same user as that of the session being queried (and <code>track_activities</code> is on)
<code>pg_stat_get_backend_activity_timestamp(integer)</code>	<code>timestamp with time zone</code>	The time at which the given server process' currently executing query was started, but only if the current user is a superuser or the same user as that of the session being queried (and <code>track_activities</code> is on)
<code>pg_stat_get_backend_xact_start_timestamp(integer)</code>	<code>timestamp with time zone</code>	The time at which the given server process' currently executing transaction was started, but only if the current user is a superuser or the same user as that of the session being queried (and <code>track_activities</code> is on)
<code>pg_stat_get_backend_start_timestamp(integer)</code>	<code>timestamp with time zone</code>	The time at which the given server process was started, or null if the current user is not a superuser nor the same user as that of the session being queried
<code>pg_stat_get_backend_client_address(integer)</code>	<code>inet</code>	The IP address of the client connected to the given server process. Null if the connection is over a Unix domain socket. Also null if the current user is not a superuser nor the same user as that of the session being queried
<code>pg_stat_get_backend_client_port(integer)</code>	<code>integer</code>	The IP port number of the client connected to the given server process. -1 if the connection is over a Unix domain socket. Null if the current user is not a superuser nor the same user as that of the session being queried
<code>pg_stat_get_bgwriter_timed_checkpoints()</code>	<code>integer</code>	The number of times the background writer has started timed checkpoints (because the <code>checkpoint_timeout</code> time has expired)

Function	Return Type	Description
<code>pg_stat_get_bgwriter_requests_done()</code>	bigint	The number of times the background writer has started checkpoints based on requests from backends because the <code>checkpoint_segments</code> has been exceeded or because the <code>CHECKPOINT</code> command has been issued
<code>pg_stat_get_bgwriter_buf_written_checkpoints()</code>	bigint	The number of buffers written by the background writer during checkpoints
<code>pg_stat_get_bgwriter_buf_written_clean()</code>	bigint	The number of buffers written by the background writer for routine cleaning of dirty pages
<code>pg_stat_get_bgwriter_maxwritten_clean()</code>	bigint	The number of times the background writer has stopped its cleaning scan because it has written more buffers than specified in the <code>bgwriter_lru_maxpages</code> parameter
<code>pg_stat_get_buf_written_backend()</code>	bigint	The number of buffers written by backends because they needed to allocate a new buffer
<code>pg_stat_get_buf_alloc()</code>	bigint	The total number of buffer allocations
<code>pg_stat_clear_snapshot()</code>	void	Discard the current statistics snapshot
<code>pg_stat_reset()</code>	void	Reset all statistics counters for the current database to zero (requires superuser privileges)

**Note:** `blocks_fetched` minus `blocks_hit` gives the number of kernel `read()` calls issued for the table, index, or database; but the actual number of physical reads is usually lower due to kernel-level buffering.

The function `pg_stat_get_backend_idset` provides a convenient way to generate one row for each active server process. For example, to show the PIDs and current queries of all server processes:

```
SELECT pg_stat_get_backend_pid(s.backendid) AS procpid,
       pg_stat_get_backend_activity(s.backendid) AS current_query
FROM (SELECT pg_stat_get_backend_idset() AS backendid) AS s;
```

## 26.3. Viewing Locks

Another useful tool for monitoring database activity is the `pg_locks` system table. It allows the database administrator to view information about the outstanding locks in the lock manager. For example, this capability can be used to:

- View all the locks currently outstanding, all the locks on relations in a particular database, all the locks on a particular relation, or all the locks held by a particular PostgreSQL session.
- Determine the relation in the current database with the most ungranted locks (which might be a source of contention among database clients).
- Determine the effect of lock contention on overall database performance, as well as the extent to which contention varies with overall database traffic.

Details of the `pg_locks` view appear in Section 44.46. For more information on locking and managing concurrency with PostgreSQL, refer to Chapter 13.

## 26.4. Dynamic Tracing

PostgreSQL provides facilities to support dynamic tracing of the database server. This allows an external utility to be called at specific points in the code and thereby trace execution. Currently, this facility is primarily intended for use by database developers, as it requires substantial familiarity with the code.

A number of trace points, often called probes, are already inserted into the source code. By default these probes are disabled, and the user needs to explicitly tell the configure script to make the probes available in PostgreSQL.

Currently, only the DTrace utility is supported, which is only available on Solaris Express and Solaris 10+. It is expected that DTrace will be available in the future on FreeBSD and Mac OS X. Supporting other dynamic tracing utilities is theoretically possible by changing the definitions for the `PG_TRACE` macros in `src/include/pg_trace.h`.

### 26.4.1. Compiling for Dynamic Tracing

By default, trace points are disabled, so you will need to explicitly tell the configure script to make the probes available in PostgreSQL. To include DTrace support specify `--enable-dtrace` to configure. See Section 15.5 for further information.

### 26.4.2. Built-in Trace Points

A few standard trace points are provided in the source code (of course, more can be added as needed for a particular problem). These are shown in Table 26-3.

**Table 26-3. Built-in Trace Points**

Name	Parameters	Overview
------	------------	----------

Name	Parameters	Overview
transaction__start	(int transactionId)	The start of a new transaction.
transaction__commit	(int transactionId)	The successful completion of a transaction.
transaction__abort	(int transactionId)	The unsuccessful completion of a transaction.
lwlock__acquire	(int lockid, int mode)	An LWLock has been acquired.
lwlock__release	(int lockid, int mode)	An LWLock has been released.
lwlock__startwait	(int lockid, int mode)	An LWLock was not immediately available and a backend has begun to wait for the lock to become available.
lwlock__endwait	(int lockid, int mode)	A backend has been released from its wait for an LWLock.
lwlock__condacquire	(int lockid, int mode)	An LWLock was successfully acquired when the caller specified no waiting.
lwlock__condacquire__fail	(int lockid, int mode)	An LWLock was not successfully acquired when the caller specified no waiting.
lock__startwait	(int locktag_field2, int lockmode)	A request for a heavyweight lock (lmgr lock) has begun to wait because the lock is not available.
lock__endwait	(int locktag_field2, int lockmode)	A request for a heavyweight lock (lmgr lock) has finished waiting (i.e., has acquired the lock).

### 26.4.3. Using Trace Points

The example below shows a DTrace script for analyzing transaction counts on the system, as an alternative to snapshotting `pg_stat_database` before and after a performance test:

```
#!/usr/sbin/dtrace -qs

postgresql$1:::transaction-start
{
    @start["Start"] = count();
    self->ts = timestamp;
}

postgresql$1:::transaction-abort
{
    @abort["Abort"] = count();
}
```

```

postgresql$1::transaction-commit
/self->ts/
{
    @commit["Commit"] = count();
    @time["Total time (ns)"] = sum(timestamp - self->ts);
    self->ts=0;
}

```

Note how the double underline in trace point names needs to be replaced by a hyphen when using D script. When executed, the example D script gives output such as:

```

# ./txn_count.d `pgrep -n postgres`
^C

Start                                71
Commit                              70
Total time (ns)                      2312105013

```

You should remember that trace programs need to be carefully written and debugged prior to their use, otherwise the trace information collected might be meaningless. In most cases where problems are found it is the instrumentation that is at fault, not the underlying system. When discussing information found using dynamic tracing, be sure to enclose the script used to allow that too to be checked and discussed.

## 26.4.4. Defining Trace Points

New trace points can be defined within the code wherever the developer desires, though this will require a recompilation.

A trace point can be inserted by using one of the trace macros. These are chosen according to how many variables will be made available for inspection at that trace point. Tracing the occurrence of an event can be achieved with a single line, using just the trace point name, e.g.:

```
PG_TRACE (my__new__trace__point);
```

More complex trace points can be provided with one or more variables for inspection by the dynamic tracing utility by using the `PG_TRACEn` macro that corresponds to the number of parameters after the trace point name:

```
PG_TRACE3 (my__complex__event, varX, varY, varZ);
```

The definition of the `transaction__start` trace point is shown below:

```

static void
StartTransaction(void)
{
    ...

    /*
     * generate a new transaction id

```

```

    */
    s->transactionId = GetNewTransactionId(false);

    XactLockTableInsert(s->transactionId);

    PG_TRACE1(transaction__start, s->transactionId);

    ...
}

```

Note how the transaction ID is made available to the dynamic tracing utility.

The dynamic tracing utility might require you to further define these trace points. For example, DTrace requires you to add new probes to the file `src/backend/utils/probes.d` as shown here:

```

provider postgresql {
    ...
    probe transaction__start(int);
    ...
};

```

You should take care that the data types specified for the probe arguments match the data types of the variables used in the `PG_TRACE` macro. This is not checked at compile time. You can check that your newly added trace point is available by recompiling, then running the new binary, and as root, executing a DTrace command such as:

```

dtrace -l -n transaction-start

```

# Chapter 27. Monitoring Disk Usage

This chapter discusses how to monitor the disk usage of a PostgreSQL database system.

## 27.1. Determining Disk Usage

Each table has a primary heap disk file where most of the data is stored. If the table has any columns with potentially-wide values, there is also a TOAST file associated with the table, which is used to store values too wide to fit comfortably in the main table (see Section 53.2). There will be one index on the TOAST table, if present. There might also be indexes associated with the base table. Each table and index is stored in a separate disk file — possibly more than one file, if the file would exceed one gigabyte. Naming conventions for these files are described in Section 53.1.

You can monitor disk space from three ways: using SQL functions listed in Table 9-54, using `VACUUM` information, and from the command line using the tools in `contrib/oid2name`. The SQL functions are the easiest to use and report information about tables, tables with indexes and long value storage (TOAST), databases, and tablespaces.

Using `psql` on a recently vacuumed or analyzed database, you can issue queries to see the disk usage of any table:

```
SELECT relfilenode, relpages FROM pg_class WHERE relname = 'customer';
```

```
 relfilenode | relpages
-----+-----
          16806 |          60
(1 row)
```

Each page is typically 8 kilobytes. (Remember, `relpages` is only updated by `VACUUM`, `ANALYZE`, and a few DDL commands such as `CREATE INDEX`.) The `relfilenode` value is of interest if you want to examine the table's disk file directly.

To show the space used by TOAST tables, use a query like the following:

```
SELECT relname, relpages
FROM pg_class,
     (SELECT reltoastrelid FROM pg_class
      WHERE relname = 'customer') ss
WHERE oid = ss.reltoastrelid
      OR oid = (SELECT reltoastidxid FROM pg_class
               WHERE oid = ss.reltoastrelid)
ORDER BY relname;
```

```
 relname          | relpages
-----+-----
pg_toast_16806    |          0
pg_toast_16806_index |          1
```

You can easily display index sizes, too:

```
SELECT c2.relname, c2.relpages
FROM pg_class c, pg_class c2, pg_index i
WHERE c.relname = 'customer'
      AND c.oid = i.indrelid
      AND c2.oid = i.indexrelid
ORDER BY c2.relname;
```

relname	relpages
customer_id_index	26

It is easy to find your largest tables and indexes using this information:

```
SELECT relname, relpages FROM pg_class ORDER BY relpages DESC;
```

relname	relpages
bigtable	3290
customer	3144

You can also use `contrib/oid2name` to show disk usage. See `README.oid2name` in that directory for examples. It includes a script that shows disk usage for each database.

## 27.2. Disk Full Failure

The most important disk monitoring task of a database administrator is to make sure the disk doesn't grow full. A filled data disk will not result in data corruption, but it might prevent useful activity from occurring. If the disk holding the WAL files grows full, database server panic and consequent shutdown might occur.

If you cannot free up additional space on the disk by deleting other things, you can move some of the database files to other file systems by making use of tablespaces. See Section 20.6 for more information about that.

**Tip:** Some file systems perform badly when they are almost full, so do not wait until the disk is completely full to take action.

If your system supports per-user disk quotas, then the database will naturally be subject to whatever quota is placed on the user the server runs as. Exceeding the quota will have the same bad effects as running out of space entirely.

# Chapter 28. Reliability and the Write-Ahead Log

This chapter explains how the Write-Ahead Log is used to obtain efficient, reliable operation.

## 28.1. Reliability

Reliability is an important property of any serious database system, and PostgreSQL does everything possible to guarantee reliable operation. One aspect of reliable operation is that all data recorded by a committed transaction should be stored in a nonvolatile area that is safe from power loss, operating system failure, and hardware failure (except failure of the nonvolatile area itself, of course). Successfully writing the data to the computer's permanent storage (disk drive or equivalent) ordinarily meets this requirement. In fact, even if a computer is fatally damaged, if the disk drives survive they can be moved to another computer with similar hardware and all committed transactions will remain intact.

While forcing data periodically to the disk platters might seem like a simple operation, it is not. Because disk drives are dramatically slower than main memory and CPUs, several layers of caching exist between the computer's main memory and the disk platters. First, there is the operating system's buffer cache, which caches frequently requested disk blocks and combines disk writes. Fortunately, all operating systems give applications a way to force writes from the buffer cache to disk, and PostgreSQL uses those features. (See the `wal_sync_method` parameter to adjust how this is done.)

Next, there might be a cache in the disk drive controller; this is particularly common on RAID controller cards. Some of these caches are *write-through*, meaning writes are passed along to the drive as soon as they arrive. Others are *write-back*, meaning data is passed on to the drive at some later time. Such caches can be a reliability hazard because the memory in the disk controller cache is volatile, and will lose its contents in a power failure. Better controller cards have *battery-backed* caches, meaning the card has a battery that maintains power to the cache in case of system power loss. After power is restored the data will be written to the disk drives.

And finally, most disk drives have caches. Some are write-through while some are write-back, and the same concerns about data loss exist for write-back drive caches as exist for disk controller caches. Consumer-grade IDE and SATA drives are particularly likely to have write-back caches that will not survive a power failure. To check write caching on Linux use `hdparm -I`; it is enabled if there is a `*` next to `Write cache`. `hdparm -W` to turn off write caching. On FreeBSD use `atacontrol`. (For SCSI disks use `sdparm`<sup>1</sup> to turn off `WCE`.) On Solaris the disk write cache is controlled by `format -e`<sup>2</sup>. (The Solaris ZFS file system is safe with disk write-cache enabled because it issues its own disk cache flush commands.) On Windows if `wal_sync_method` is `open_datasync` (the default), write caching is disabled by unchecking `My Computer\Open\{select disk drive}\Properties\Hardware\Properties\Policies\Enable write caching on the disk`. Also on Windows, `fsync` and `fsync_writethrough` never do write caching.

When the operating system sends a write request to the disk hardware, there is little it can do to make sure the data has arrived at a truly non-volatile storage area. Rather, it is the administrator's responsibility to be sure that all storage components ensure data integrity. Avoid disk controllers that have non-battery-backed write caches. At the drive level, disable write-back caching if the drive cannot guarantee the data will be written before shutdown.

1. <http://sg.torque.net/sg/sdparm.html>

2. [http://www.sun.com/bigadmin/content/submitted/format\\_utility.jsp](http://www.sun.com/bigadmin/content/submitted/format_utility.jsp)

Another risk of data loss is posed by the disk platter write operations themselves. Disk platters are divided into sectors, commonly 512 bytes each. Every physical read or write operation processes a whole sector. When a write request arrives at the drive, it might be for 512 bytes, 1024 bytes, or 8192 bytes, and the process of writing could fail due to power loss at any time, meaning some of the 512-byte sectors were written, and others were not. To guard against such failures, PostgreSQL periodically writes full page images to permanent storage *before* modifying the actual page on disk. By doing this, during crash recovery PostgreSQL can restore partially-written pages. If you have a battery-backed disk controller or file-system software that prevents partial page writes (e.g., ReiserFS 4), you can turn off this page imaging by using the `full_page_writes` parameter.

## 28.2. Write-Ahead Logging (WAL)

*Write-Ahead Logging* (WAL) is a standard method for ensuring data integrity. A detailed description can be found in most (if not all) books about transaction processing. Briefly, WAL's central concept is that changes to data files (where tables and indexes reside) must be written only after those changes have been logged, that is, after log records describing the changes have been flushed to permanent storage. If we follow this procedure, we do not need to flush data pages to disk on every transaction commit, because we know that in the event of a crash we will be able to recover the database using the log: any changes that have not been applied to the data pages can be redone from the log records. (This is roll-forward recovery, also known as REDO.)

Using WAL results in a significantly reduced number of disk writes, because only the log file needs to be flushed to disk to guarantee that a transaction is committed, rather than every data file changed by the transaction. The log file is written sequentially, and so the cost of syncing the log is much less than the cost of flushing the data pages. This is especially true for servers handling many small transactions touching different parts of the data store. Furthermore, when the server is processing many small concurrent transactions, one `fsync` of the log file may suffice to commit many transactions.

WAL also makes it possible to support on-line backup and point-in-time recovery, as described in Section 24.3. By archiving the WAL data we can support reverting to any time instant covered by the available WAL data: we simply install a prior physical backup of the database, and replay the WAL log just as far as the desired time. What's more, the physical backup doesn't have to be an instantaneous snapshot of the database state — if it is made over some period of time, then replaying the WAL log for that period will fix any internal inconsistencies.

## 28.3. Asynchronous Commit

*Asynchronous commit* is an option that allows transactions to complete more quickly, at the cost that the most recent transactions may be lost if the database should crash. In many applications this is an acceptable trade-off.

As described in the previous section, transaction commit is normally *synchronous*: the server waits for the transaction's WAL records to be flushed to permanent storage before returning a success indication to the client. The client is therefore guaranteed that a transaction reported to be committed will be preserved, even in the event of a server crash immediately after. However, for short transactions this delay is a major component of the total transaction time. Selecting asynchronous commit mode means that the server

returns success as soon as the transaction is logically completed, before the WAL records it generated have actually made their way to disk. This can provide a significant boost in throughput for small transactions.

Asynchronous commit introduces the risk of data loss. There is a short time window between the report of transaction completion to the client and the time that the transaction is truly committed (that is, it is guaranteed not to be lost if the server crashes). Thus asynchronous commit should not be used if the client will take external actions relying on the assumption that the transaction will be remembered. As an example, a bank would certainly not use asynchronous commit for a transaction recording an ATM's dispensing of cash. But in many scenarios, such as event logging, there is no need for a strong guarantee of this kind.

The risk that is taken by using asynchronous commit is of data loss, not data corruption. If the database should crash, it will recover by replaying WAL up to the last record that was flushed. The database will therefore be restored to a self-consistent state, but any transactions that were not yet flushed to disk will not be reflected in that state. The net effect is therefore loss of the last few transactions. Because the transactions are replayed in commit order, no inconsistency can be introduced — for example, if transaction B made changes relying on the effects of a previous transaction A, it is not possible for A's effects to be lost while B's effects are preserved.

The user can select the commit mode of each transaction, so that it is possible to have both synchronous and asynchronous commit transactions running concurrently. This allows flexible trade-offs between performance and certainty of transaction durability. The commit mode is controlled by the user-settable parameter `synchronous_commit`, which can be changed in any of the ways that a configuration parameter can be set. The mode used for any one transaction depends on the value of `synchronous_commit` when transaction commit begins.

Certain utility commands, for instance `DROP TABLE`, are forced to commit synchronously regardless of the setting of `synchronous_commit`. This is to ensure consistency between the server's file system and the logical state of the database. The commands supporting two-phase commit, such as `PREPARE TRANSACTION`, are also always synchronous.

If the database crashes during the risk window between an asynchronous commit and the writing of the transaction's WAL records, then changes made during that transaction *will* be lost. The duration of the risk window is limited because a background process (the “WAL writer”) flushes unwritten WAL records to disk every `wal_writer_delay` milliseconds. The actual maximum duration of the risk window is three times `wal_writer_delay` because the WAL writer is designed to favor writing whole pages at a time during busy periods.

### Caution

An immediate-mode shutdown is equivalent to a server crash, and will therefore cause loss of any unflushed asynchronous commits.

Asynchronous commit provides behavior different from setting `fsync = off`. `fsync` is a server-wide setting that will alter the behavior of all transactions. It disables all logic within PostgreSQL that attempts to synchronize writes to different portions of the database, and therefore a system crash (that is, a hardware or operating system crash, not a failure of PostgreSQL itself) could result in arbitrarily bad corruption of the database state. In many scenarios, asynchronous commit provides most of the performance improvement that could be obtained by turning off `fsync`, but without the risk of data corruption.

`commit_delay` also sounds very similar to asynchronous commit, but it is actually a synchronous commit method (in fact, `commit_delay` is ignored during an asynchronous commit). `commit_delay` causes a

delay just before a synchronous commit attempts to flush WAL to disk, in the hope that a single flush executed by one such transaction can also serve other transactions committing at about the same time. Setting `commit_delay` can only help when there are many concurrently committing transactions, and it is difficult to tune it to a value that actually helps rather than hurting throughput.

## 28.4. WAL Configuration

There are several WAL-related configuration parameters that affect database performance. This section explains their use. Consult Chapter 18 for general information about setting server configuration parameters.

*Checkpoints* are points in the sequence of transactions at which it is guaranteed that the data files have been updated with all information written before the checkpoint. At checkpoint time, all dirty data pages are flushed to disk and a special checkpoint record is written to the log file. In the event of a crash, the crash recovery procedure looks at the latest checkpoint record to determine the point in the log (known as the redo record) from which it should start the REDO operation. Any changes made to data files before that point are known to be already on disk. Hence, after a checkpoint has been made, any log segments preceding the one containing the redo record are no longer needed and can be recycled or removed. (When WAL archiving is being done, the log segments must be archived before being recycled or removed.)

The server's background writer process will automatically perform a checkpoint every so often. A checkpoint is created every `checkpoint_segments` log segments, or every `checkpoint_timeout` seconds, whichever comes first. The default settings are 3 segments and 300 seconds respectively. It is also possible to force a checkpoint by using the SQL command `CHECKPOINT`.

Reducing `checkpoint_segments` and/or `checkpoint_timeout` causes checkpoints to be done more often. This allows faster after-crash recovery (since less work will need to be redone). However, one must balance this against the increased cost of flushing dirty data pages more often. If `full_page_writes` is set (as is the default), there is another factor to consider. To ensure data page consistency, the first modification of a data page after each checkpoint results in logging the entire page content. In that case, a smaller checkpoint interval increases the volume of output to the WAL log, partially negating the goal of using a smaller interval, and in any case causing more disk I/O.

Checkpoints are fairly expensive, first because they require writing out all currently dirty buffers, and second because they result in extra subsequent WAL traffic as discussed above. It is therefore wise to set the checkpointing parameters high enough that checkpoints don't happen too often. As a simple sanity check on your checkpointing parameters, you can set the `checkpoint_warning` parameter. If checkpoints happen closer together than `checkpoint_warning` seconds, a message will be output to the server log recommending increasing `checkpoint_segments`. Occasional appearance of such a message is not cause for alarm, but if it appears often then the checkpoint control parameters should be increased. Bulk operations such as large `COPY` transfers might cause a number of such warnings to appear if you have not set `checkpoint_segments` high enough.

To avoid flooding the I/O system with a burst of page writes, writing dirty buffers during a checkpoint is spread over a period of time. That period is controlled by `checkpoint_completion_target`, which is given as a fraction of the checkpoint interval. The I/O rate is adjusted so that the checkpoint finishes when the given fraction of `checkpoint_segments` WAL segments have been consumed since checkpoint start, or the given fraction of `checkpoint_timeout` seconds have elapsed, whichever is sooner. With the default value of 0.5, PostgreSQL can be expected to complete each checkpoint in about half

the time before the next checkpoint starts. On a system that's very close to maximum I/O throughput during normal operation, you might want to increase `checkpoint_completion_target` to reduce the I/O load from checkpoints. The disadvantage of this is that prolonging checkpoints affects recovery time, because more WAL segments will need to be kept around for possible use in recovery. Although `checkpoint_completion_target` can be set as high as 1.0, it is best to keep it less than that (perhaps 0.9 at most) since checkpoints include some other activities besides writing dirty buffers. A setting of 1.0 is quite likely to result in checkpoints not being completed on time, which would result in performance loss due to unexpected variation in the number of WAL segments needed.

There will always be at least one WAL segment file, and will normally not be more than  $(2 + \text{checkpoint\_completion\_target}) * \text{checkpoint\_segments} + 1$  files. Each segment file is normally 16 MB (though this size can be altered when building the server). You can use this to estimate space requirements for WAL. Ordinarily, when old log segment files are no longer needed, they are recycled (renamed to become the next segments in the numbered sequence). If, due to a short-term peak of log output rate, there are more than  $3 * \text{checkpoint\_segments} + 1$  segment files, the unneeded segment files will be deleted instead of recycled until the system gets back under this limit.

There are two commonly used internal WAL functions: `LogInsert` and `LogFlush`. `LogInsert` is used to place a new record into the WAL buffers in shared memory. If there is no space for the new record, `LogInsert` will have to write (move to kernel cache) a few filled WAL buffers. This is undesirable because `LogInsert` is used on every database low level modification (for example, row insertion) at a time when an exclusive lock is held on affected data pages, so the operation needs to be as fast as possible. What is worse, writing WAL buffers might also force the creation of a new log segment, which takes even more time. Normally, WAL buffers should be written and flushed by a `LogFlush` request, which is made, for the most part, at transaction commit time to ensure that transaction records are flushed to permanent storage. On systems with high log output, `LogFlush` requests might not occur often enough to prevent `LogInsert` from having to do writes. On such systems one should increase the number of WAL buffers by modifying the configuration parameter `wal_buffers`. The default number of WAL buffers is 8. Increasing this value will correspondingly increase shared memory usage. When `full_page_writes` is set and the system is very busy, setting this value higher will help smooth response times during the period immediately following each checkpoint.

The `commit_delay` parameter defines for how many microseconds the server process will sleep after writing a commit record to the log with `LogInsert` but before performing a `LogFlush`. This delay allows other server processes to add their commit records to the log so as to have all of them flushed with a single log sync. No sleep will occur if `fsync` is not enabled, nor if fewer than `commit_siblings` other sessions are currently in active transactions; this avoids sleeping when it's unlikely that any other session will commit soon. Note that on most platforms, the resolution of a sleep request is ten milliseconds, so that any nonzero `commit_delay` setting between 1 and 10000 microseconds would have the same effect. Good values for these parameters are not yet clear; experimentation is encouraged.

The `wal_sync_method` parameter determines how PostgreSQL will ask the kernel to force WAL updates out to disk. All the options should be the same as far as reliability goes, but it's quite platform-specific which one will be the fastest. Note that this parameter is irrelevant if `fsync` has been turned off.

Enabling the `wal_debug` configuration parameter (provided that PostgreSQL has been compiled with support for it) will result in each `LogInsert` and `LogFlush` WAL call being logged to the server log. This option might be replaced by a more general mechanism in the future.

## 28.5. WAL Internals

WAL is automatically enabled; no action is required from the administrator except ensuring that the disk-space requirements for the WAL logs are met, and that any necessary tuning is done (see Section 28.4).

WAL logs are stored in the directory `pg_xlog` under the data directory, as a set of segment files, normally each 16 MB in size. Each segment is divided into pages, normally 8 kB each. The log record headers are described in `access/xlog.h`; the record content is dependent on the type of event that is being logged. Segment files are given ever-increasing numbers as names, starting at `000000010000000000000000`. The numbers do not wrap, at present, but it should take a very very long time to exhaust the available stock of numbers.

It is of advantage if the log is located on another disk than the main database files. This can be achieved by moving the directory `pg_xlog` to another location (while the server is shut down, of course) and creating a symbolic link from the original location in the main data directory to the new location.

The aim of WAL, to ensure that the log is written before database records are altered, can be subverted by disk drives that falsely report a successful write to the kernel, when in fact they have only cached the data and not yet stored it on the disk. A power failure in such a situation might still lead to irrecoverable data corruption. Administrators should try to ensure that disks holding PostgreSQL's WAL log files do not make such false reports.

After a checkpoint has been made and the log flushed, the checkpoint's position is saved in the file `pg_control`. Therefore, when recovery is to be done, the server first reads `pg_control` and then the checkpoint record; then it performs the REDO operation by scanning forward from the log position indicated in the checkpoint record. Because the entire content of data pages is saved in the log on the first page modification after a checkpoint, all pages changed since the checkpoint will be restored to a consistent state.

To deal with the case where `pg_control` is corrupted, we should support the possibility of scanning existing log segments in reverse order — newest to oldest — in order to find the latest checkpoint. This has not been implemented yet. `pg_control` is small enough (less than one disk page) that it is not subject to partial-write problems, and as of this writing there have been no reports of database failures due solely to inability to read `pg_control` itself. So while it is theoretically a weak spot, `pg_control` does not seem to be a problem in practice.

# Chapter 29. Regression Tests

The regression tests are a comprehensive set of tests for the SQL implementation in PostgreSQL. They test standard SQL operations as well as the extended capabilities of PostgreSQL.

## 29.1. Running the Tests

The regression tests can be run against an already installed and running server, or using a temporary installation within the build tree. Furthermore, there is a “parallel” and a “sequential” mode for running the tests. The sequential method runs each test script in turn, whereas the parallel method starts up multiple server processes to run groups of tests in parallel. Parallel testing gives confidence that interprocess communication and locking are working correctly. For historical reasons, the sequential test is usually run against an existing installation and the parallel method against a temporary installation, but there are no technical reasons for this.

To run the regression tests after building but before installation, type

```
gmake check
```

in the top-level directory. (Or you can change to `src/test/regress` and run the command there.) This will first build several auxiliary files, such as some sample user-defined trigger functions, and then run the test driver script. At the end you should see something like

```
=====
All 100 tests passed.
=====
```

or otherwise a note about which tests failed. See Section 29.2 below before assuming that a “failure” represents a serious problem.

Because this test method runs a temporary server, it will not work when you are the root user (since the server will not start as root). If you already did the build as root, you do not have to start all over. Instead, make the regression test directory writable by some other user, log in as that user, and restart the tests. For example

```
root# chmod -R a+w src/test/regress
root# chmod -R a+w contrib/spi
root# su - joeuser
joeuser$ cd top-level build directory
joeuser$ gmake check
```

(The only possible “security risk” here is that other users might be able to alter the regression test results behind your back. Use common sense when managing user permissions.)

Alternatively, run the tests after installation.

If you have configured PostgreSQL to install into a location where an older PostgreSQL installation already exists, and you perform `gmake check` before installing the new version, you might find that the tests fail because the new programs try to use the already-installed shared libraries. (Typical symptoms are complaints about undefined symbols.) If you wish to run the tests before overwriting the old installation,

you'll need to build with `configure --disable-rpath`. It is not recommended that you use this option for the final installation, however.

The parallel regression test starts quite a few processes under your user ID. Presently, the maximum concurrency is twenty parallel test scripts, which means forty processes: there's a server process and a `psql` process for each test script. So if your system enforces a per-user limit on the number of processes, make sure this limit is at least fifty or so, else you might get random-seeming failures in the parallel test. If you are not in a position to raise the limit, you can cut down the degree of parallelism by setting the `MAX_CONNECTIONS` parameter. For example,

```
gmake MAX_CONNECTIONS=10 check
```

runs no more than ten tests concurrently.

To run the tests after installation (see Chapter 15), initialize a data area and start the server, as explained in Chapter 17, then type

```
gmake installcheck
```

or for a parallel test

```
gmake installcheck-parallel
```

The tests will expect to contact the server at the local host and the default port number, unless directed otherwise by `PGHOST` and `PGPORT` environment variables.

The source distribution also contains regression tests for the optional procedural languages and for some of the `contrib` modules. At present, these tests can be used only against an already-installed server. To run the tests for all procedural languages that have been built and installed, change to the `src/pl` directory of the build tree and type

```
gmake installcheck
```

You can also do this in any of the subdirectories of `src/pl` to run tests for just one procedural language. To run the tests for all `contrib` modules that have them, change to the `contrib` directory of the build tree and type

```
gmake installcheck
```

The `contrib` modules must have been built and installed first. You can also do this in a subdirectory of `contrib` to run the tests for just one module.

## 29.2. Test Evaluation

Some properly installed and fully functional PostgreSQL installations can “fail” some of these regression tests due to platform-specific artifacts such as varying floating-point representation and message wording. The tests are currently evaluated using a simple `diff` comparison against the outputs generated on a reference system, so the results are sensitive to small system differences. When a test is reported as “failed”, always examine the differences between expected and actual results; you might find that the differences are not significant. Nonetheless, we still strive to maintain accurate reference files across all supported platforms, so it can be expected that all tests pass.

The actual outputs of the regression tests are in files in the `src/test/regress/results` directory. The test script uses `diff` to compare each output file against the reference outputs stored in the `src/test/regress/expected` directory. Any differences are saved for your inspection in `src/test/regress/regression.diffs`. (Or you can run `diff` yourself, if you prefer.)

If for some reason a particular platform generates a “failure” for a given test, but inspection of the output convinces you that the result is valid, you can add a new comparison file to silence the failure report in future test runs. See Section 29.3 for details.

### 29.2.1. Error message differences

Some of the regression tests involve intentional invalid input values. Error messages can come from either the PostgreSQL code or from the host platform system routines. In the latter case, the messages can vary between platforms, but should reflect similar information. These differences in messages will result in a “failed” regression test that can be validated by inspection.

### 29.2.2. Locale differences

If you run the tests against an already-installed server that was initialized with a collation-order locale other than C, then there might be differences due to sort order and follow-up failures. The regression test suite is set up to handle this problem by providing alternative result files that together are known to handle a large number of locales.

### 29.2.3. Date and time differences

Most of the date and time results are dependent on the time zone environment. The reference files are generated for time zone `PST8PDT` (Berkeley, California), and there will be apparent failures if the tests are not run with that time zone setting. The regression test driver sets environment variable `PGTZ` to `PST8PDT`, which normally ensures proper results.

### 29.2.4. Floating-point differences

Some of the tests involve computing 64-bit floating-point numbers (`double precision`) from table columns. Differences in results involving mathematical functions of `double precision` columns have been observed. The `float8` and `geometry` tests are particularly prone to small differences across platforms, or even with different compiler optimization options. Human eyeball comparison is needed to determine the real significance of these differences which are usually 10 places to the right of the decimal point.

Some systems display minus zero as `-0`, while others just show `0`.

Some systems signal errors from `pow()` and `exp()` differently from the mechanism expected by the current PostgreSQL code.

### 29.2.5. Row ordering differences

You might see differences in which the same rows are output in a different order than what appears in the expected file. In most cases this is not, strictly speaking, a bug. Most of the regression test scripts are not so pedantic as to use an `ORDER BY` for every single `SELECT`, and so their result row orderings are not well-defined according to the letter of the SQL specification. In practice, since we are looking at the same queries being executed on the same data by the same software, we usually get the same result ordering on all platforms, and so the lack of `ORDER BY` isn't a problem. Some queries do exhibit cross-platform ordering differences, however. When testing against an already-installed server, ordering differences can also be caused by non-C locale settings or non-default parameter settings, such as custom values of `work_mem` or the planner cost parameters.

Therefore, if you see an ordering difference, it's not something to worry about, unless the query does have an `ORDER BY` that your result is violating. But please report it anyway, so that we can add an `ORDER BY` to that particular query and thereby eliminate the bogus "failure" in future releases.

You might wonder why we don't order all the regression test queries explicitly to get rid of this issue once and for all. The reason is that that would make the regression tests less useful, not more, since they'd tend to exercise query plan types that produce ordered results to the exclusion of those that don't.

### 29.2.6. Insufficient stack depth

If the `errors` test results in a server crash at the `select infinite_recurse()` command, it means that the platform's limit on process stack size is smaller than the `max_stack_depth` parameter indicates. This can be fixed by running the server under a higher stack size limit (4MB is recommended with the default value of `max_stack_depth`). If you are unable to do that, an alternative is to reduce the value of `max_stack_depth`.

### 29.2.7. The "random" test

The `random` test script is intended to produce random results. In rare cases, this causes the random regression test to fail. Typing:

```
diff results/random.out expected/random.out
```

should produce only one or a few lines of differences. You need not worry unless the random test fails repeatedly.

## 29.3. Variant Comparison Files

Since some of the tests inherently produce environment-dependent results, we have provided ways to specify alternative "expected" result files. Each regression test can have several comparison files showing possible results on different platforms. There are two independent mechanisms for determining which comparison file is used for each test.

The first mechanism allows comparison files to be selected for specific platforms. There is a mapping file, `src/test/regress/resultmap`, that defines which comparison file to use for each platform. To eliminate bogus test “failures” for a particular platform, you first choose or make a variant result file, and then add a line to the `resultmap` file.

Each line in the mapping file is of the form

```
testname:output:platformpattern=comparisonfilename
```

The test name is just the name of the particular regression test module. The output value indicates which output file to check. For the standard regression tests, this is always `out`. The value corresponds to the file extension of the output file. The platform pattern is a pattern in the style of the Unix tool `expr` (that is, a regular expression with an implicit `^` anchor at the start). It is matched against the platform name as printed by `config.guess`. The comparison file name is the base name of the substitute result comparison file.

For example: some systems interpret very small floating-point values as zero, rather than reporting an underflow error. This causes a few differences in the `float8` regression test. Therefore, we provide a variant comparison file, `float8-small-is-zero.out`, which includes the results to be expected on these systems. To silence the bogus “failure” message on OpenBSD platforms, `resultmap` includes:

```
float8:out:i.86-.*-openbsd=float8-small-is-zero.out
```

which will trigger on any machine for which the output of `config.guess` matches `i.86-.*-openbsd`. Other lines in `resultmap` select the variant comparison file for other platforms where it’s appropriate.

The second selection mechanism for variant comparison files is much more automatic: it simply uses the “best match” among several supplied comparison files. The regression test driver script considers both the standard comparison file for a test, `testname.out`, and variant files named `testname_digit.out` (where the *digit* is any single digit 0-9). If any such file is an exact match, the test is considered to pass; otherwise, the one that generates the shortest diff is used to create the failure report. (If `resultmap` includes an entry for the particular test, then the base `testname` is the substitute name given in `resultmap`.)

For example, for the `char` test, the comparison file `char.out` contains results that are expected in the C and POSIX locales, while the file `char_1.out` contains results sorted as they appear in many other locales.

The best-match mechanism was devised to cope with locale-dependent results, but it can be used in any situation where the test results cannot be predicted easily from the platform name alone. A limitation of this mechanism is that the test driver cannot tell which variant is actually “correct” for the current environment; it will just pick the variant that seems to work best. Therefore it is safest to use this mechanism only for variant results that you are willing to consider equally valid in all contexts.

## IV. Client Interfaces

This part describes the client programming interfaces distributed with PostgreSQL. Each of these chapters can be read independently. Note that there are many other programming interfaces for client programs that are distributed separately and contain their own documentation (Appendix G lists some of the more popular ones). Readers of this part should be familiar with using SQL commands to manipulate and query the database (see Part II) and of course with the programming language that the interface uses.

# Chapter 30. libpq - C Library

libpq is the C application programmer's interface to PostgreSQL. libpq is a set of library functions that allow client programs to pass queries to the PostgreSQL backend server and to receive the results of these queries.

libpq is also the underlying engine for several other PostgreSQL application interfaces, including those written for C++, Perl, Python, Tcl and ECPG. So some aspects of libpq's behavior will be important to you if you use one of those packages. In particular, Section 30.12, Section 30.13 and Section 30.16 describe behavior that is visible to the user of any application that uses libpq.

Some short programs are included at the end of this chapter (Section 30.19) to show how to write programs that use libpq. There are also several complete examples of libpq applications in the directory `src/test/examples` in the source code distribution.

Client programs that use libpq must include the header file `libpq-fe.h` and must link with the libpq library.

## 30.1. Database Connection Control Functions

The following functions deal with making a connection to a PostgreSQL backend server. An application program can have several backend connections open at one time. (One reason to do that is to access more than one database.) Each connection is represented by a `PGconn` object, which is obtained from the function `PQconnectdb` or `PQsetdbLogin`. Note that these functions will always return a non-null object pointer, unless perhaps there is too little memory even to allocate the `PGconn` object. The `PQstatus` function should be called to check whether a connection was successfully made before queries are sent via the connection object.

`PQconnectdb`

Makes a new connection to the database server.

```
PGconn *PQconnectdb(const char *conninfo);
```

This function opens a new database connection using the parameters taken from the string `conninfo`. Unlike `PQsetdbLogin` below, the parameter set can be extended without changing the function signature, so use of this function (or its nonblocking analogues `PQconnectStart` and `PQconnectPoll`) is preferred for new application programming.

The passed string can be empty to use all default parameters, or it can contain one or more parameter settings separated by whitespace. Each parameter setting is in the form `keyword = value`. Spaces around the equal sign are optional. To write an empty value or a value containing spaces, surround it with single quotes, e.g., `keyword = 'a value'`. Single quotes and backslashes within the value must be escaped with a backslash, i.e., `\'` and `\\`.

The currently recognized parameter key words are:

`host`

Name of host to connect to. If this begins with a slash, it specifies Unix-domain communication rather than TCP/IP communication; the value is the name of the directory in which the socket

file is stored. The default behavior when `host` is not specified is to connect to a Unix-domain socket in `/tmp` (or whatever socket directory was specified when PostgreSQL was built). On machines without Unix-domain sockets, the default is to connect to `localhost`.

#### `hostaddr`

Numeric IP address of host to connect to. This should be in the standard IPv4 address format, e.g., `172.28.40.9`. If your machine supports IPv6, you can also use those addresses. TCP/IP communication is always used when a nonempty string is specified for this parameter.

Using `hostaddr` instead of `host` allows the application to avoid a host name look-up, which might be important in applications with time constraints. However, Kerberos and GSSAPI authentication requires the host name. The following therefore applies: If `host` is specified without `hostaddr`, a host name lookup occurs. If `hostaddr` is specified without `host`, the value for `hostaddr` gives the remote address. When Kerberos is used, a reverse name query occurs to obtain the host name for Kerberos. If both `host` and `hostaddr` are specified, the value for `hostaddr` gives the remote address; the value for `host` is ignored, unless Kerberos is used, in which case that value is used for Kerberos authentication. (Note that authentication is likely to fail if libpq is passed a host name that is not the name of the machine at `hostaddr`.) Also, `host` rather than `hostaddr` is used to identify the connection in `~/.pgpass` (see Section 30.13).

Without either a host name or host address, libpq will connect using a local Unix-domain socket; or on machines without Unix-domain sockets, it will attempt to connect to `localhost`.

#### `port`

Port number to connect to at the server host, or socket file name extension for Unix-domain connections.

#### `dbname`

The database name. Defaults to be the same as the user name.

#### `user`

PostgreSQL user name to connect as. Defaults to be the same as the operating system name of the user running the application.

#### `password`

Password to be used if the server demands password authentication.

#### `connect_timeout`

Maximum wait for connection, in seconds (write as a decimal integer string). Zero or not specified means wait indefinitely. It is not recommended to use a timeout of less than 2 seconds.

#### `options`

Command-line options to be sent to the server.

#### `tty`

Ignored (formerly, this specified where to send server debug output).

#### `sslmode`

This option determines whether or with what priority an SSL connection will be negotiated with the server. There are four modes: `disable` will attempt only an unencrypted SSL connection;

`allow` will negotiate, trying first a non-SSL connection, then if that fails, trying an SSL connection; `prefer` (the default) will negotiate, trying first an SSL connection, then if that fails, trying a regular non-SSL connection; `require` will try only an SSL connection.

If PostgreSQL is compiled without SSL support, using option `require` will cause an error, while options `allow` and `prefer` will be accepted but libpq will not in fact attempt an SSL connection.

`requiressl`

This option is deprecated in favor of the `sslmode` setting.

If set to 1, an SSL connection to the server is required (this is equivalent to `sslmode require`). libpq will then refuse to connect if the server does not accept an SSL connection. If set to 0 (default), libpq will negotiate the connection type with the server (equivalent to `sslmode prefer`). This option is only available if PostgreSQL is compiled with SSL support.

`krbsrvname`

Kerberos service name to use when authenticating with Kerberos 5 or GSSAPI. This must match the service name specified in the server configuration for Kerberos authentication to succeed. (See also Section 21.2.5 and Section 21.2.3.)

`gsslib`

GSS library to use for GSSAPI authentication. Only used on Windows. Set to `gssapi` to force libpq to use the GSSAPI library for authentication instead of the default SSPI.

`service`

Service name to use for additional parameters. It specifies a service name in `pg_service.conf` that holds additional connection parameters. This allows applications to specify only a service name so connection parameters can be centrally maintained. See Section 30.14.

If any parameter is unspecified, then the corresponding environment variable (see Section 30.12) is checked. If the environment variable is not set either, then the indicated built-in defaults are used.

`PQsetdbLogin`

Makes a new connection to the database server.

```
PGconn *PQsetdbLogin(const char *pghost,
                    const char *pgport,
                    const char *pgoptions,
                    const char *pgtty,
                    const char *dbName,
                    const char *login,
                    const char *pwd);
```

This is the predecessor of `PQconnectdb` with a fixed set of parameters. It has the same functionality except that the missing parameters will always take on default values. Write `NULL` or an empty string for any one of the fixed parameters that is to be defaulted.

If the `dbName` contains an `=` sign, it is taken as a `conninfo` string in exactly the same way as if it had been passed to `PQconnectdb`, and the remaining parameters are then applied as above.

PQsetdb

Makes a new connection to the database server.

```
PGconn *PQsetdb(char *pghost,
                char *pgport,
                char *pgoptions,
                char *pgtty,
                char *dbName);
```

This is a macro that calls `PQsetdbLogin` with null pointers for the `login` and `pwd` parameters. It is provided for backward compatibility with very old programs.

PQconnectStart

PQconnectPoll

Make a connection to the database server in a nonblocking manner.

```
PGconn *PQconnectStart(const char *conninfo);

PostgresPollingStatusType PQconnectPoll(PGconn *conn);
```

These two functions are used to open a connection to a database server such that your application's thread of execution is not blocked on remote I/O whilst doing so. The point of this approach is that the waits for I/O to complete can occur in the application's main loop, rather than down inside `PQconnectdb`, and so the application can manage this operation in parallel with other activities.

The database connection is made using the parameters taken from the string `conninfo`, passed to `PQconnectStart`. This string is in the same format as described above for `PQconnectdb`.

Neither `PQconnectStart` nor `PQconnectPoll` will block, so long as a number of restrictions are met:

- The `hostaddr` and `host` parameters are used appropriately to ensure that name and reverse name queries are not made. See the documentation of these parameters under `PQconnectdb` above for details.
- If you call `PQtrace`, ensure that the stream object into which you trace will not block.
- You ensure that the socket is in the appropriate state before calling `PQconnectPoll`, as described below.

To begin a nonblocking connection request, call `conn = PQconnectStart("connection_info_string")`. If `conn` is null, then libpq has been unable to allocate a new `PGconn` structure. Otherwise, a valid `PGconn` pointer is returned (though not yet representing a valid connection to the database). On return from `PQconnectStart`, call `status = PQstatus(conn)`. If `status` equals `CONNECTION_BAD`, `PQconnectStart` has failed.

If `PQconnectStart` succeeds, the next stage is to poll libpq so that it can proceed with the connection sequence. Use `PQsocket(conn)` to obtain the descriptor of the socket underlying the database connection. Loop thus: If `PQconnectPoll(conn)` last returned `PGRES_POLLING_READING`, wait until the socket is ready to read (as indicated by `select()`, `poll()`, or similar system function). Then call `PQconnectPoll(conn)` again. Conversely, if

`PQconnectPoll(conn)` last returned `PGRES_POLLING_WRITING`, wait until the socket is ready to write, then call `PQconnectPoll(conn)` again. If you have yet to call `PQconnectPoll`, i.e., just after the call to `PQconnectStart`, behave as if it last returned `PGRES_POLLING_WRITING`. Continue this loop until `PQconnectPoll(conn)` returns `PGRES_POLLING_FAILED`, indicating the connection procedure has failed, or `PGRES_POLLING_OK`, indicating the connection has been successfully made.

At any time during connection, the status of the connection can be checked by calling `PQstatus`. If this gives `CONNECTION_BAD`, then the connection procedure has failed; if it gives `CONNECTION_OK`, then the connection is ready. Both of these states are equally detectable from the return value of `PQconnectPoll`, described above. Other states might also occur during (and only during) an asynchronous connection procedure. These indicate the current stage of the connection procedure and might be useful to provide feedback to the user for example. These statuses are:

`CONNECTION_STARTED`

Waiting for connection to be made.

`CONNECTION_MADE`

Connection OK; waiting to send.

`CONNECTION_AWAITING_RESPONSE`

Waiting for a response from the server.

`CONNECTION_AUTH_OK`

Received authentication; waiting for backend start-up to finish.

`CONNECTION_SSL_STARTUP`

Negotiating SSL encryption.

`CONNECTION_SETENV`

Negotiating environment-driven parameter settings.

Note that, although these constants will remain (in order to maintain compatibility), an application should never rely upon these occurring in a particular order, or at all, or on the status always being one of these documented values. An application might do something like this:

```
switch(PQstatus(conn))
{
    case CONNECTION_STARTED:
        feedback = "Connecting...";
        break;

    case CONNECTION_MADE:
        feedback = "Connected to server...";
        break;

    .
    .
    .

    default:
        feedback = "Connecting...";
}
```

The `connect_timeout` connection parameter is ignored when using `PQconnectPoll`; it is the application's responsibility to decide whether an excessive amount of time has elapsed. Otherwise, `PQconnectStart` followed by a `PQconnectPoll` loop is equivalent to `PQconnectdb`.

Note that if `PQconnectStart` returns a non-null pointer, you must call `PQfinish` when you are finished with it, in order to dispose of the structure and any associated memory blocks. This must be done even if the connection attempt fails or is abandoned.

#### `PQconnndefaults`

Returns the default connection options.

```
PQconninfoOption *PQconnndefaults(void);
```

```
typedef struct
```

```
{
    char    *keyword;    /* The keyword of the option */
    char    *envvar;     /* Fallback environment variable name */
    char    *compiled;   /* Fallback compiled in default value */
    char    *val;        /* Option's current value, or NULL */
    char    *label;      /* Label for field in connect dialog */
    char    *dispchar;   /* Character to display for this field
                        in a connect dialog. Values are:
                        ""      Display entered value as is
                        "*"     Password field - hide value
                        "D"     Debug option - don't show by default */
    int     dispsize;    /* Field size in characters for dialog */
} PQconninfoOption;
```

Returns a connection options array. This can be used to determine all possible `PQconnectdb` options and their current default values. The return value points to an array of `PQconninfoOption` structures, which ends with an entry having a null `keyword` pointer. The null pointer is returned if memory could not be allocated. Note that the current default values (`val` fields) will depend on environment variables and other context. Callers must treat the connection options data as read-only.

After processing the options array, free it by passing it to `PQconninfoFree`. If this is not done, a small amount of memory is leaked for each call to `PQconnndefaults`.

#### `PQfinish`

Closes the connection to the server. Also frees memory used by the `PGconn` object.

```
void PQfinish(PGconn *conn);
```

Note that even if the server connection attempt fails (as indicated by `PQstatus`), the application should call `PQfinish` to free the memory used by the `PGconn` object. The `PGconn` pointer must not be used again after `PQfinish` has been called.

#### `PQreset`

Resets the communication channel to the server.

```
void PQreset(PGconn *conn);
```

This function will close the connection to the server and attempt to reestablish a new connection to the same server, using all the same parameters previously used. This might be useful for error recovery if a working connection is lost.

PQresetStart  
PQresetPoll

Reset the communication channel to the server, in a nonblocking manner.

```
int PQresetStart(PGconn *conn);

PostgresPollingStatusType PQresetPoll(PGconn *conn);
```

These functions will close the connection to the server and attempt to reestablish a new connection to the same server, using all the same parameters previously used. This can be useful for error recovery if a working connection is lost. They differ from `PQreset` (above) in that they act in a nonblocking manner. These functions suffer from the same restrictions as `PQconnectStart` and `PQconnectPoll`.

To initiate a connection reset, call `PQresetStart`. If it returns 0, the reset has failed. If it returns 1, poll the reset using `PQresetPoll` in exactly the same way as you would create the connection using `PQconnectPoll`.

## 30.2. Connection Status Functions

These functions can be used to interrogate the status of an existing database connection object.

**Tip:** libpq application programmers should be careful to maintain the `PGconn` abstraction. Use the accessor functions described below to get at the contents of `PGconn`. Reference to internal `PGconn` fields using `libpq-int.h` is not recommended because they are subject to change in the future.

The following functions return parameter values established at connection. These values are fixed for the life of the `PGconn` object.

PQdb

Returns the database name of the connection.

```
char *PQdb(const PGconn *conn);
```

PQuser

Returns the user name of the connection.

```
char *PQuser(const PGconn *conn);
```

PQpass

Returns the password of the connection.

```
char *PQpass(const PGconn *conn);
```

PQhost

Returns the server host name of the connection.

```
char *PQhost(const PGconn *conn);
```

PQport

Returns the port of the connection.

```
char *PQport(const PGconn *conn);
```

PQtty

Returns the debug TTY of the connection. (This is obsolete, since the server no longer pays attention to the TTY setting, but the function remains for backwards compatibility.)

```
char *PQtty(const PGconn *conn);
```

PQoptions

Returns the command-line options passed in the connection request.

```
char *PQoptions(const PGconn *conn);
```

The following functions return status data that can change as operations are executed on the `PGconn` object.

PQstatus

Returns the status of the connection.

```
ConnStatusType PQstatus(const PGconn *conn);
```

The status can be one of a number of values. However, only two of these are seen outside of an asynchronous connection procedure: `CONNECTION_OK` and `CONNECTION_BAD`. A good connection to the database has the status `CONNECTION_OK`. A failed connection attempt is signaled by status `CONNECTION_BAD`. Ordinarily, an OK status will remain so until `PQfinish`, but a communications failure might result in the status changing to `CONNECTION_BAD` prematurely. In that case the application could try to recover by calling `PQreset`.

See the entry for `PQconnectStart` and `PQconnectPoll` with regards to other status codes that might be seen.

PQtransactionStatus

Returns the current in-transaction status of the server.

```
PGTransactionStatusType PQtransactionStatus(const PGconn *conn);
```

The status can be `PQTRANS_IDLE` (currently idle), `PQTRANS_ACTIVE` (a command is in progress), `PQTRANS_INTRANS` (idle, in a valid transaction block), or `PQTRANS_INERROR` (idle, in a failed transaction block). `PQTRANS_UNKNOWN` is reported if the connection is bad. `PQTRANS_ACTIVE` is reported only when a query has been sent to the server and not yet completed.

### Caution

`PQtransactionStatus` will give incorrect results when using a PostgreSQL 7.3 server that has the parameter `autocommit` set to off. The server-side `autocommit` feature has been deprecated and does not exist in later server versions.

`PQparameterStatus`

Looks up a current parameter setting of the server.

```
const char *PQparameterStatus(const PGconn *conn, const char *paramName);
```

Certain parameter values are reported by the server automatically at connection startup or whenever their values change. `PQparameterStatus` can be used to interrogate these settings. It returns the current value of a parameter if known, or `NULL` if the parameter is not known.

Parameters reported as of the current release include `server_version`, `server_encoding`, `client_encoding`, `is_superuser`, `session_authorization`, `DateStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1.) Note that `server_version`, `server_encoding` and `integer_datetimes` cannot change after startup.

Pre-3.0-protocol servers do not report parameter settings, but libpq includes logic to obtain values for `server_version` and `client_encoding` anyway. Applications are encouraged to use `PQparameterStatus` rather than *ad hoc* code to determine these values. (Beware however that on a pre-3.0 connection, changing `client_encoding` via `SET` after connection startup will not be reflected by `PQparameterStatus`.) For `server_version`, see also `PQserverVersion`, which returns the information in a numeric form that is much easier to compare against.

If no value for `standard_conforming_strings` is reported, applications can assume it is `off`, that is, backslashes are treated as escapes in string literals. Also, the presence of this parameter can be taken as an indication that the escape string syntax (`E' . . .'`) is accepted.

Although the returned pointer is declared `const`, it in fact points to mutable storage associated with the `PGconn` structure. It is unwise to assume the pointer will remain valid across queries.

`PQprotocolVersion`

Interrogates the frontend/backend protocol being used.

```
int PQprotocolVersion(const PGconn *conn);
```

Applications might wish to use this to determine whether certain features are supported. Currently, the possible values are 2 (2.0 protocol), 3 (3.0 protocol), or zero (connection bad). This will not change after connection startup is complete, but it could theoretically change during a connection reset. The 3.0 protocol will normally be used when communicating with PostgreSQL 7.4 or later

servers; pre-7.4 servers support only protocol 2.0. (Protocol 1.0 is obsolete and not supported by libpq.)

#### PQserverVersion

Returns an integer representing the backend version.

```
int PQserverVersion(const PGconn *conn);
```

Applications might use this to determine the version of the database server they are connected to. The number is formed by converting the major, minor, and revision numbers into two-decimal-digit numbers and appending them together. For example, version 8.1.5 will be returned as 80105, and version 8.2 will be returned as 80200 (leading zeroes are not shown). Zero is returned if the connection is bad.

#### PQerrorMessage

Returns the error message most recently generated by an operation on the connection.

```
char *PQerrorMessage(const PGconn *conn);
```

Nearly all libpq functions will set a message for `PQerrorMessage` if they fail. Note that by libpq convention, a nonempty `PQerrorMessage` result will include a trailing newline. The caller should not free the result directly. It will be freed when the associated `PGconn` handle is passed to `PQfinish`. The result string should not be expected to remain the same across operations on the `PGconn` structure.

#### PQsocket

Obtains the file descriptor number of the connection socket to the server. A valid descriptor will be greater than or equal to 0; a result of -1 indicates that no server connection is currently open. (This will not change during normal operation, but could change during connection setup or reset.)

```
int PQsocket(const PGconn *conn);
```

#### PQbackendPID

Returns the process ID (PID) of the backend server process handling this connection.

```
int PQbackendPID(const PGconn *conn);
```

The backend PID is useful for debugging purposes and for comparison to `NOTIFY` messages (which include the PID of the notifying backend process). Note that the PID belongs to a process executing on the database server host, not the local host!

#### PQconnectionNeedsPassword

Returns true (1) if the connection authentication method required a password, but none was available. Returns false (0) if not.

```
int PQconnectionNeedsPassword(const PGconn *conn);
```

This function can be applied after a failed connection attempt to decide whether to prompt the user for a password.

**PQconnectionUsedPassword**

Returns true (1) if the connection authentication method used a caller-supplied password. Returns false (0) if not.

```
int PQconnectionUsedPassword(const PGconn *conn);
```

This function detects whether a password supplied to the connection function was actually used. Passwords obtained from other sources (such as the `.pgpass` file) are not considered caller-supplied.

**PQgetssl**

Returns the SSL structure used in the connection, or null if SSL is not in use.

```
SSL *PQgetssl(const PGconn *conn);
```

This structure can be used to verify encryption levels, check server certificates, and more. Refer to the OpenSSL documentation for information about this structure.

You must define `USE_SSL` in order to get the correct prototype for this function. Doing this will also automatically include `ssl.h` from OpenSSL.

## 30.3. Command Execution Functions

Once a connection to a database server has been successfully established, the functions described here are used to perform SQL queries and commands.

### 30.3.1. Main Functions

**PQexec**

Submits a command to the server and waits for the result.

```
PGresult *PQexec(PGconn *conn, const char *command);
```

Returns a `PGresult` pointer or possibly a null pointer. A non-null pointer will generally be returned except in out-of-memory conditions or serious errors such as inability to send the command to the server. If a null pointer is returned, it should be treated like a `PGRES_FATAL_ERROR` result. Use `PQerrorMessage` to get more information about such errors.

It is allowed to include multiple SQL commands (separated by semicolons) in the command string. Multiple queries sent in a single `PQexec` call are processed in a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the query string to divide it into multiple transactions. Note however that the returned `PGresult` structure describes only the result of the last command executed from the string. Should one of the commands fail, processing of the string stops with it and the returned `PGresult` describes the error condition.

`PQexecParams`

Submits a command to the server and waits for the result, with the ability to pass parameters separately from the SQL command text.

```
PQresult *PQexecParams(PGconn *conn,
                        const char *command,
                        int nParams,
                        const Oid *paramTypes,
                        const char * const *paramValues,
                        const int *paramLengths,
                        const int *paramFormats,
                        int resultFormat);
```

`PQexecParams` is like `PQexec`, but offers additional functionality: parameter values can be specified separately from the command string proper, and query results can be requested in either text or binary format. `PQexecParams` is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The function arguments are:

`conn`

The connection object to send the command through.

`command`

The SQL command string to be executed. If parameters are used, they are referred to in the command string as `$1`, `$2`, etc.

`nParams`

The number of parameters supplied; it is the length of the arrays `paramTypes[]`, `paramValues[]`, `paramLengths[]`, and `paramFormats[]`. (The array pointers can be NULL when `nParams` is zero.)

`paramTypes[]`

Specifies, by OID, the data types to be assigned to the parameter symbols. If `paramTypes` is NULL, or any particular element in the array is zero, the server infers a data type for the parameter symbol in the same way it would do for an untyped literal string.

`paramValues[]`

Specifies the actual values of the parameters. A null pointer in this array means the corresponding parameter is null; otherwise the pointer points to a zero-terminated text string (for text format) or binary data in the format expected by the server (for binary format).

`paramLengths[]`

Specifies the actual data lengths of binary-format parameters. It is ignored for null parameters and text-format parameters. The array pointer can be null when there are no binary parameters.

`paramFormats[]`

Specifies whether parameters are text (put a zero in the array entry for the corresponding parameter) or binary (put a one in the array entry for the corresponding parameter). If the array pointer is null then all parameters are presumed to be text strings.

`resultFormat`

Specify zero to obtain results in text format, or one to obtain results in binary format. (There is not currently a provision to obtain different result columns in different formats, although that is possible in the underlying protocol.)

The primary advantage of `PQexecParams` over `PQexec` is that parameter values can be separated from the command string, thus avoiding the need for tedious and error-prone quoting and escaping.

Unlike `PQexec`, `PQexecParams` allows at most one SQL command in the given string. (There can be semicolons in it, but not more than one nonempty command.) This is a limitation of the underlying protocol, but has some usefulness as an extra defense against SQL-injection attacks.

**Tip:** Specifying parameter types via OIDs is tedious, particularly if you prefer not to hard-wire particular OID values into your program. However, you can avoid doing so even in cases where the server by itself cannot determine the type of the parameter, or chooses a different type than you want. In the SQL command text, attach an explicit cast to the parameter symbol to show what data type you will send. For example:

```
SELECT * FROM mytable WHERE x = $1::bigint;
```

This forces parameter `$1` to be treated as `bigint`, whereas by default it would be assigned the same type as `x`. Forcing the parameter type decision, either this way or by specifying a numeric type OID, is strongly recommended when sending parameter values in binary format, because binary format has less redundancy than text format and so there is less chance that the server will detect a type mismatch mistake for you.

`PQprepare`

Submits a request to create a prepared statement with the given parameters, and waits for completion.

```
PGresult *PQprepare(PGconn *conn,
                    const char *stmtName,
                    const char *query,
                    int nParams,
                    const Oid *paramTypes);
```

`PQprepare` creates a prepared statement for later execution with `PQexecPrepared`. This feature allows commands that will be used repeatedly to be parsed and planned just once, rather than each time they are executed. `PQprepare` is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The function creates a prepared statement named `stmtName` from the `query` string, which must contain a single SQL command. `stmtName` can be "" to create an unnamed statement, in which case any pre-existing unnamed statement is automatically replaced; otherwise it is an error if the statement name is already defined in the current session. If any parameters are used, they are referred to in the query as `$1`, `$2`, etc. `nParams` is the number of parameters for which types are pre-specified in the array `paramTypes[]`. (The array pointer can be `NULL` when `nParams` is zero.) `paramTypes[]` specifies, by OID, the data types to be assigned to the parameter symbols. If `paramTypes` is `NULL`,

or any particular element in the array is zero, the server assigns a data type to the parameter symbol in the same way it would do for an untyped literal string. Also, the query can use parameter symbols with numbers higher than `nParams`; data types will be inferred for these symbols as well. (See `PQdescribePrepared` for a means to find out what data types were inferred.)

As with `PQexec`, the result is normally a `PGresult` object whose contents indicate server-side success or failure. A null result indicates out-of-memory or inability to send the command at all. Use `PQerrorMessage` to get more information about such errors.

Prepared statements for use with `PQexecPrepared` can also be created by executing SQL *PREPARE* statements. (But `PQprepare` is more flexible since it does not require parameter types to be pre-specified.) Also, although there is no libpq function for deleting a prepared statement, the SQL *DEALLOCATE* statement can be used for that purpose.

#### `PQexecPrepared`

Sends a request to execute a prepared statement with given parameters, and waits for the result.

```
PGresult *PQexecPrepared(PGconn *conn,
                        const char *stmtName,
                        int nParams,
                        const char * const *paramValues,
                        const int *paramLengths,
                        const int *paramFormats,
                        int resultFormat);
```

`PQexecPrepared` is like `PQexecParams`, but the command to be executed is specified by naming a previously-prepared statement, instead of giving a query string. This feature allows commands that will be used repeatedly to be parsed and planned just once, rather than each time they are executed. The statement must have been prepared previously in the current session. `PQexecPrepared` is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

The parameters are identical to `PQexecParams`, except that the name of a prepared statement is given instead of a query string, and the `paramTypes[]` parameter is not present (it is not needed since the prepared statement's parameter types were determined when it was created).

#### `PQdescribePrepared`

Submits a request to obtain information about the specified prepared statement, and waits for completion.

```
PGresult *PQdescribePrepared(PGconn *conn, const char *stmtName);
```

`PQdescribePrepared` allows an application to obtain information about a previously prepared statement. `PQdescribePrepared` is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

`stmtName` can be "" or NULL to reference the unnamed statement, otherwise it must be the name of an existing prepared statement. On success, a `PGresult` with status `PGRES_COMMAND_OK` is returned. The functions `PQnparams` and `PQparamtype` can be applied to this `PGresult` to obtain information about the parameters of the prepared statement, and the functions `PQnfields`, `PQfname`, `PQftype`, etc provide information about the result columns (if any) of the statement.

`PQdescribePortal`

Submits a request to obtain information about the specified portal, and waits for completion.

```
PGresult *PQdescribePortal(PGconn *conn, const char *portalName);
```

`PQdescribePortal` allows an application to obtain information about a previously created portal. (libpq does not provide any direct access to portals, but you can use this function to inspect the properties of a cursor created with a `DECLARE CURSOR SQL` command.) `PQdescribePortal` is supported only in protocol 3.0 and later connections; it will fail when using protocol 2.0.

`portalName` can be "" or NULL to reference the unnamed portal, otherwise it must be the name of an existing portal. On success, a `PGresult` with status `PGRES_COMMAND_OK` is returned. The functions `PQnfields`, `PQfname`, `PQftype`, etc can be applied to the `PGresult` to obtain information about the result columns (if any) of the portal.

The `PGresult` structure encapsulates the result returned by the server. libpq application programmers should be careful to maintain the `PGresult` abstraction. Use the accessor functions below to get at the contents of `PGresult`. Avoid directly referencing the fields of the `PGresult` structure because they are subject to change in the future.

`PQresultStatus`

Returns the result status of the command.

```
ExecStatusType PQresultStatus(const PGresult *res);
```

`PQresultStatus` can return one of the following values:

`PGRES_EMPTY_QUERY`

The string sent to the server was empty.

`PGRES_COMMAND_OK`

Successful completion of a command returning no data.

`PGRES_TUPLES_OK`

Successful completion of a command returning data (such as a `SELECT` or `SHOW`).

`PGRES_COPY_OUT`

Copy Out (from server) data transfer started.

`PGRES_COPY_IN`

Copy In (to server) data transfer started.

`PGRES_BAD_RESPONSE`

The server's response was not understood.

`PGRES_NONFATAL_ERROR`

A nonfatal error (a notice or warning) occurred.

`PGRES_FATAL_ERROR`

A fatal error occurred.

If the result status is `PGRES_TUPLES_OK`, then the functions described below can be used to retrieve the rows returned by the query. Note that a `SELECT` command that happens to retrieve zero rows still shows `PGRES_TUPLES_OK`. `PGRES_COMMAND_OK` is for commands that can never return rows (`INSERT`, `UPDATE`, etc.). A response of `PGRES_EMPTY_QUERY` might indicate a bug in the client software.

A result of status `PGRES_NONFATAL_ERROR` will never be returned directly by `PQexec` or other query execution functions; results of this kind are instead passed to the notice processor (see Section 30.11).

`PQresStatus`

Converts the enumerated type returned by `PQresultStatus` into a string constant describing the status code. The caller should not free the result.

```
char *PQresStatus(ExecStatusType status);
```

`PQresultErrorMessage`

Returns the error message associated with the command, or an empty string if there was no error.

```
char *PQresultErrorMessage(const PGresult *res);
```

If there was an error, the returned string will include a trailing newline. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

Immediately following a `PQexec` or `PQgetResult` call, `PQerrorMessage` (on the connection) will return the same string as `PQresultErrorMessage` (on the result). However, a `PGresult` will retain its error message until destroyed, whereas the connection's error message will change when subsequent operations are done. Use `PQresultErrorMessage` when you want to know the status associated with a particular `PGresult`; use `PQerrorMessage` when you want to know the status from the latest operation on the connection.

`PQresultErrorField`

Returns an individual field of an error report.

```
char *PQresultErrorField(const PGresult *res, int fieldcode);
```

`fieldcode` is an error field identifier; see the symbols listed below. `NULL` is returned if the `PGresult` is not an error or warning result, or does not include the specified field. Field values will normally not include a trailing newline. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

The following field codes are available:

`PG_DIAG_SEVERITY`

The severity; the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message), or a localized translation of one of these. Always present.

`PG_DIAG_SQLSTATE`

The SQLSTATE code for the error. The SQLSTATE code identifies the type of error that has occurred; it can be used by front-end applications to perform specific operations (such as error handling) in response to a particular database error. For a list of the possible SQLSTATE codes, see Appendix A. This field is not localizable, and is always present.

`PG_DIAG_MESSAGE_PRIMARY`

The primary human-readable error message (typically one line). Always present.

`PG_DIAG_MESSAGE_DETAIL`

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

`PG_DIAG_MESSAGE_HINT`

Hint: an optional suggestion what to do about the problem. This is intended to differ from detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

`PG_DIAG_STATEMENT_POSITION`

A string containing a decimal integer indicating an error cursor position as an index into the original statement string. The first character has index 1, and positions are measured in characters not bytes.

`PG_DIAG_INTERNAL_POSITION`

This is defined the same as the `PG_DIAG_STATEMENT_POSITION` field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The `PG_DIAG_INTERNAL_QUERY` field will always appear when this field appears.

`PG_DIAG_INTERNAL_QUERY`

The text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

`PG_DIAG_CONTEXT`

An indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

`PG_DIAG_SOURCE_FILE`

The file name of the source-code location where the error was reported.

`PG_DIAG_SOURCE_LINE`

The line number of the source-code location where the error was reported.

`PG_DIAG_SOURCE_FUNCTION`

The name of the source-code function reporting the error.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

Errors generated internally by libpq will have severity and primary message, but typically no other fields. Errors returned by a pre-3.0-protocol server will include severity and primary message, and sometimes a detail message, but no other fields.

Note that error fields are only available from `PGresult` objects, not `PGconn` objects; there is no `PQerrorField` function.

#### `PQclear`

Frees the storage associated with a `PGresult`. Every command result should be freed via `PQclear` when it is no longer needed.

```
void PQclear(PGresult *res);
```

You can keep a `PGresult` object around for as long as you need it; it does not go away when you issue a new command, nor even if you close the connection. To get rid of it, you must call `PQclear`. Failure to do this will result in memory leaks in your application.

#### `PQmakeEmptyPGresult`

Constructs an empty `PGresult` object with the given status.

```
PGresult *PQmakeEmptyPGresult(PGconn *conn, ExecStatusType status);
```

This is libpq's internal function to allocate and initialize an empty `PGresult` object. This function returns `NULL` if memory could not be allocated. It is exported because some applications find it useful to generate result objects (particularly objects with error status) themselves. If `conn` is not null and `status` indicates an error, the current error message of the specified connection is copied into the `PGresult`. Note that `PQclear` should eventually be called on the object, just as with a `PGresult` returned by libpq itself.

## 30.3.2. Retrieving Query Result Information

These functions are used to extract information from a `PGresult` object that represents a successful query result (that is, one that has status `PGRES_TUPLES_OK`). They can also be used to extract information from a successful Describe operation: a Describe's result has all the same column information that actual execution of the query would provide, but it has zero rows. For objects with other status values, these functions will act as though the result has zero rows and zero columns.

#### `PQntuples`

Returns the number of rows (tuples) in the query result. Because it returns an integer result, large result sets might overflow the return value on 32-bit operating systems.

```
int PQntuples(const PGresult *res);
```

#### `PQnfields`

Returns the number of columns (fields) in each row of the query result.

```
int PQnfields(const PGresult *res);
```

**PQfname**

Returns the column name associated with the given column number. Column numbers start at 0. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

```
char *PQfname(const PGresult *res,
              int column_number);
```

`NULL` is returned if the column number is out of range.

**PQfnumber**

Returns the column number associated with the given column name.

```
int PQfnumber(const PGresult *res,
              const char *column_name);
```

-1 is returned if the given name does not match any column.

The given name is treated like an identifier in an SQL command, that is, it is downcased unless double-quoted. For example, given a query result generated from the SQL command:

```
SELECT 1 AS FOO, 2 AS "BAR";
```

we would have the results:

<code>PQfname(res, 0)</code>	<code>foo</code>
<code>PQfname(res, 1)</code>	<code>BAR</code>
<code>PQfnumber(res, "FOO")</code>	<code>0</code>
<code>PQfnumber(res, "foo")</code>	<code>0</code>
<code>PQfnumber(res, "BAR")</code>	<code>-1</code>
<code>PQfnumber(res, "\"BAR\"")</code>	<code>1</code>

**PQftable**

Returns the OID of the table from which the given column was fetched. Column numbers start at 0.

```
Oid PQftable(const PGresult *res,
             int column_number);
```

`InvalidOid` is returned if the column number is out of range, or if the specified column is not a simple reference to a table column, or when using pre-3.0 protocol. You can query the system table `pg_class` to determine exactly which table is referenced.

The type `Oid` and the constant `InvalidOid` will be defined when you include the libpq header file. They will both be some integer type.

**PQftablecol**

Returns the column number (within its table) of the column making up the specified query result column. Query-result column numbers start at 0, but table columns have nonzero numbers.

```
int PQftablecol(const PGresult *res,
                int column_number);
```

Zero is returned if the column number is out of range, or if the specified column is not a simple reference to a table column, or when using pre-3.0 protocol.

**PQffformat**

Returns the format code indicating the format of the given column. Column numbers start at 0.

```
int PQffformat(const PGresult *res,
               int column_number);
```

Format code zero indicates textual data representation, while format code one indicates binary representation. (Other codes are reserved for future definition.)

**PQftype**

Returns the data type associated with the given column number. The integer returned is the internal OID number of the type. Column numbers start at 0.

```
Oid PQftype(const PGresult *res,
             int column_number);
```

You can query the system table `pg_type` to obtain the names and properties of the various data types. The OIDs of the built-in data types are defined in the file `src/include/catalog/pg_type.h` in the source tree.

**PQfmod**

Returns the type modifier of the column associated with the given column number. Column numbers start at 0.

```
int PQfmod(const PGresult *res,
            int column_number);
```

The interpretation of modifier values is type-specific; they typically indicate precision or size limits. The value -1 is used to indicate “no information available”. Most data types do not use modifiers, in which case the value is always -1.

**PQfsize**

Returns the size in bytes of the column associated with the given column number. Column numbers start at 0.

```
int PQfsize(const PGresult *res,
             int column_number);
```

`PQfsize` returns the space allocated for this column in a database row, in other words the size of the server’s internal representation of the data type. (Accordingly, it is not really very useful to clients.) A negative value indicates the data type is variable-length.

**PQbinaryTuples**

Returns 1 if the `PGresult` contains binary data and 0 if it contains text data.

```
int PQbinaryTuples(const PGresult *res);
```

This function is deprecated (except for its use in connection with `COPY`), because it is possible for a single `PGresult` to contain text data in some columns and binary data in others. `PQffformat` is preferred. `PQbinaryTuples` returns 1 only if all columns of the result are binary (format 1).

`PQgetvalue`

Returns a single field value of one row of a `PGresult`. Row and column numbers start at 0. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

```
char *PQgetvalue(const PGresult *res,
                 int row_number,
                 int column_number);
```

For data in text format, the value returned by `PQgetvalue` is a null-terminated character string representation of the field value. For data in binary format, the value is in the binary representation determined by the data type's `typsend` and `typeceive` functions. (The value is actually followed by a zero byte in this case too, but that is not ordinarily useful, since the value is likely to contain embedded nulls.)

An empty string is returned if the field value is null. See `PQgetisnull` to distinguish null values from empty-string values.

The pointer returned by `PQgetvalue` points to storage that is part of the `PGresult` structure. One should not modify the data it points to, and one must explicitly copy the data into other storage if it is to be used past the lifetime of the `PGresult` structure itself.

`PQgetisnull`

Tests a field for a null value. Row and column numbers start at 0.

```
int PQgetisnull(const PGresult *res,
                int row_number,
                int column_number);
```

This function returns 1 if the field is null and 0 if it contains a non-null value. (Note that `PQgetvalue` will return an empty string, not a null pointer, for a null field.)

`PQgetlength`

Returns the actual length of a field value in bytes. Row and column numbers start at 0.

```
int PQgetlength(const PGresult *res,
                int row_number,
                int column_number);
```

This is the actual data length for the particular data value, that is, the size of the object pointed to by `PQgetvalue`. For text data format this is the same as `strlen()`. For binary format this is essential information. Note that one should *not* rely on `PQfsize` to obtain the actual data length.

`PQnparams`

Returns the number of parameters of a prepared statement.

```
int PQnparams(const PGresult *res);
```

This function is only useful when inspecting the result of `PQdescribePrepared`. For other types of queries it will return zero.

**PQparamtype**

Returns the data type of the indicated statement parameter. Parameter numbers start at 0.

```
Oid PQparamtype(const PGresult *res, int param_number);
```

This function is only useful when inspecting the result of `PQdescribePrepared`. For other types of queries it will return zero.

**PQprint**

Prints out all the rows and, optionally, the column names to the specified output stream.

```
void PQprint(FILE *fout,          /* output stream */
             const PGresult *res,
             const PQprintOpt *po);

typedef struct {
    pqbool  header;      /* print output field headings and row count */
    pqbool  align;       /* fill align the fields */
    pqbool  standard;    /* old brain dead format */
    pqbool  html3;       /* output HTML tables */
    pqbool  expanded;    /* expand tables */
    pqbool  pager;       /* use pager for output if needed */
    char    *fieldSep;   /* field separator */
    char    *tableOpt;   /* attributes for HTML table element */
    char    *caption;    /* HTML table caption */
    char    **fieldName; /* null-terminated array of replacement field names */
} PQprintOpt;
```

This function was formerly used by `psql` to print query results, but this is no longer the case. Note that it assumes all the data is in text format.

### 30.3.3. Retrieving Result Information for Other Commands

These functions are used to extract information from `PGresult` objects that are not `SELECT` results.

**PQcmdStatus**

Returns the command status tag from the SQL command that generated the `PGresult`.

```
char *PQcmdStatus(PGresult *res);
```

Commonly this is just the name of the command, but it might include additional data such as the number of rows processed. The caller should not free the result directly. It will be freed when the associated `PGresult` handle is passed to `PQclear`.

**PQcmdTuples**

Returns the number of rows affected by the SQL command.

```
char *PQcmdTuples(PGresult *res);
```

This function returns a string containing the number of rows affected by the SQL statement that generated the `PGresult`. This function can only be used following the execution of an `INSERT`,

UPDATE, DELETE, MOVE, FETCH, or COPY statement, or an EXECUTE of a prepared query that contains an INSERT, UPDATE, or DELETE statement. If the command that generated the PGresult was anything else, PQcmdTuples returns an empty string. The caller should not free the return value directly. It will be freed when the associated PGresult handle is passed to PQclear.

PQoidValue

Returns the OID of the inserted row, if the SQL command was an INSERT that inserted exactly one row into a table that has OIDs, or a EXECUTE of a prepared query containing a suitable INSERT statement. Otherwise, this function returns InvalidOid. This function will also return InvalidOid if the table affected by the INSERT statement does not contain OIDs.

```
Oid PQoidValue(const PGresult *res);
```

PQoidStatus

Returns a string with the OID of the inserted row, if the SQL command was an INSERT that inserted exactly one row, or a EXECUTE of a prepared statement consisting of a suitable INSERT. (The string will be 0 if the INSERT did not insert exactly one row, or if the target table does not have OIDs.) If the command was not an INSERT, returns an empty string.

```
char *PQoidStatus(const PGresult *res);
```

This function is deprecated in favor of PQoidValue. It is not thread-safe.

### 30.3.4. Escaping Strings for Inclusion in SQL Commands

PQescapeStringConn escapes a string for use within an SQL command. This is useful when inserting data values as literal constants in SQL commands. Certain characters (such as quotes and backslashes) must be escaped to prevent them from being interpreted specially by the SQL parser. PQescapeStringConn performs this operation.

**Tip:** It is especially important to do proper escaping when handling strings that were received from an untrustworthy source. Otherwise there is a security risk: you are vulnerable to “SQL injection” attacks wherein unwanted SQL commands are fed to your database.

Note that it is not necessary nor correct to do escaping when a data value is passed as a separate parameter in PQexecParams or its sibling routines.

```
size_t PQescapeStringConn (PGconn *conn,
                           char *to, const char *from, size_t length,
                           int *error);
```

PQescapeStringConn writes an escaped version of the from string to the to buffer, escaping special characters so that they cannot cause any harm, and adding a terminating zero byte. The single quotes that must surround PostgreSQL string literals are not included in the result string; they should be provided in the SQL command that the result is inserted into. The parameter from points to the first character of

the string that is to be escaped, and the `length` parameter gives the number of bytes in this string. A terminating zero byte is not required, and should not be counted in `length`. (If a terminating zero byte is found before `length` bytes are processed, `PQescapeStringConn` stops at the zero; the behavior is thus rather like `strncpy`.) `to` shall point to a buffer that is able to hold at least one more byte than twice the value of `length`, otherwise the behavior is undefined. Behavior is likewise undefined if the `to` and `from` strings overlap.

If the `error` parameter is not `NULL`, then `*error` is set to zero on success, nonzero on error. Presently the only possible error conditions involve invalid multibyte encoding in the source string. The output string is still generated on error, but it can be expected that the server will reject it as malformed. On error, a suitable message is stored in the `conn` object, whether or not `error` is `NULL`.

`PQescapeStringConn` returns the number of bytes written to `to`, not including the terminating zero byte.

```
size_t PQescapeString (char *to, const char *from, size_t length);
```

`PQescapeString` is an older, deprecated version of `PQescapeStringConn`; the difference is that it does not take `conn` or `error` parameters. Because of this, it cannot adjust its behavior depending on the connection properties (such as character encoding) and therefore *it might give the wrong results*. Also, it has no way to report error conditions.

`PQescapeString` can be used safely in single-threaded client programs that work with only one PostgreSQL connection at a time (in this case it can find out what it needs to know “behind the scenes”). In other contexts it is a security hazard and should be avoided in favor of `PQescapeStringConn`.

### 30.3.5. Escaping Binary Strings for Inclusion in SQL Commands

`PQescapeByteaConn`

Escapes binary data for use within an SQL command with the type `bytea`. As with `PQescapeStringConn`, this is only used when inserting data directly into an SQL command string.

```
unsigned char *PQescapeByteaConn(PGconn *conn,
                                const unsigned char *from,
                                size_t from_length,
                                size_t *to_length);
```

Certain byte values *must* be escaped (but all byte values *can* be escaped) when used as part of a `bytea` literal in an SQL statement. In general, to escape a byte, it is converted into the three digit octal number equal to the octet value, and preceded by usually two backslashes. The single quote (`'`) and backslash (`\`) characters have special alternative escape sequences. See Section 8.4 for more information. `PQescapeByteaConn` performs this operation, escaping only the minimally required bytes.

The `from` parameter points to the first byte of the string that is to be escaped, and the `from_length` parameter gives the number of bytes in this binary string. (A terminating zero byte is neither necessary nor counted.) The `to_length` parameter points to a variable that will hold the resultant escaped string length. This result string length includes the terminating zero byte of the result.

`PQescapeByteaConn` returns an escaped version of the `from` parameter binary string in memory allocated with `malloc()`. This memory must be freed using `PQfreemem()` when the result is no longer needed. The return string has all special characters replaced so that they can be properly processed by the PostgreSQL string literal parser, and the `bytea` input function. A terminating zero byte is also added. The single quotes that must surround PostgreSQL string literals are not part of the result string.

On error, a NULL pointer is returned, and a suitable error message is stored in the `conn` object. Currently, the only possible error is insufficient memory for the result string.

#### `PQescapeBytea`

`PQescapeBytea` is an older, deprecated version of `PQescapeByteaConn`.

```
unsigned char *PQescapeBytea(const unsigned char *from,
                             size_t from_length,
                             size_t *to_length);
```

The only difference from `PQescapeByteaConn` is that `PQescapeBytea` does not take a `PGconn` parameter. Because of this, it cannot adjust its behavior depending on the connection properties (in particular, whether standard-conforming strings are enabled) and therefore *it might give the wrong results*. Also, it has no way to return an error message on failure.

`PQescapeBytea` can be used safely in single-threaded client programs that work with only one PostgreSQL connection at a time (in this case it can find out what it needs to know “behind the scenes”). In other contexts it is a security hazard and should be avoided in favor of `PQescapeByteaConn`.

#### `PQunescapeBytea`

Converts a string representation of binary data into binary data — the reverse of `PQescapeBytea`. This is needed when retrieving `bytea` data in text format, but not when retrieving it in binary format.

```
unsigned char *PQunescapeBytea(const unsigned char *from, size_t *to_length);
```

The `from` parameter points to a string such as might be returned by `PQgetvalue` when applied to a `bytea` column. `PQunescapeBytea` converts this string representation into its binary representation. It returns a pointer to a buffer allocated with `malloc()`, or null on error, and puts the size of the buffer in `to_length`. The result must be freed using `PQfreemem` when it is no longer needed.

This conversion is not exactly the inverse of `PQescapeBytea`, because the string is not expected to be “escaped” when received from `PQgetvalue`. In particular this means there is no need for string quoting considerations, and so no need for a `PGconn` parameter.

#### `PQfreemem`

Frees memory allocated by libpq.

```
void PQfreemem(void *ptr);
```

Frees memory allocated by libpq, particularly `PQescapeByteaConn`, `PQescapeBytea`, `PQunescapeBytea`, and `PQnotifies`. It is particularly important that this function, rather than `free()`, be used on Microsoft Windows. This is because allocating memory in a DLL and releasing it in the application works only if multithreaded/single-threaded, release/debug, and static/dynamic flags are the same for the DLL and the application. On non-Microsoft Windows platforms, this function is the same as the standard library function `free()`.

## 30.4. Asynchronous Command Processing

The `PQexec` function is adequate for submitting commands in normal, synchronous applications. It has a couple of deficiencies, however, that can be of importance to some users:

- `PQexec` waits for the command to be completed. The application might have other work to do (such as maintaining a user interface), in which case it won't want to block waiting for the response.
- Since the execution of the client application is suspended while it waits for the result, it is hard for the application to decide that it would like to try to cancel the ongoing command. (It can be done from a signal handler, but not otherwise.)
- `PQexec` can return only one `PGresult` structure. If the submitted command string contains multiple SQL commands, all but the last `PGresult` are discarded by `PQexec`.

Applications that do not like these limitations can instead use the underlying functions that `PQexec` is built from: `PQsendQuery` and `PQgetResult`. There are also `PQsendQueryParams`, `PQsendPrepare`, `PQsendQueryPrepared`, `PQsendDescribePrepared`, and `PQsendDescribePortal`, which can be used with `PQgetResult` to duplicate the functionality of `PQexecParams`, `PQprepare`, `PQexecPrepared`, `PQdescribePrepared`, and `PQdescribePortal` respectively.

### `PQsendQuery`

Submits a command to the server without waiting for the result(s). 1 is returned if the command was successfully dispatched and 0 if not (in which case, use `PQerrorMessage` to get more information about the failure).

```
int PQsendQuery(PGconn *conn, const char *command);
```

After successfully calling `PQsendQuery`, call `PQgetResult` one or more times to obtain the results. `PQsendQuery` cannot be called again (on the same connection) until `PQgetResult` has returned a null pointer, indicating that the command is done.

### `PQsendQueryParams`

Submits a command and separate parameters to the server without waiting for the result(s).

```
int PQsendQueryParams(PGconn *conn,
                     const char *command,
                     int nParams,
                     const Oid *paramTypes,
                     const char * const *paramValues,
```

```
const int *paramLengths,
const int *paramFormats,
int resultFormat);
```

This is equivalent to `PQsendQuery` except that query parameters can be specified separately from the query string. The function's parameters are handled identically to `PQexecParams`. Like `PQexecParams`, it will not work on 2.0-protocol connections, and it allows only one command in the query string.

#### `PQsendPrepare`

Sends a request to create a prepared statement with the given parameters, without waiting for completion.

```
int PQsendPrepare(PGconn *conn,
                  const char *stmtName,
                  const char *query,
                  int nParams,
                  const Oid *paramTypes);
```

This is an asynchronous version of `PQprepare`: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call `PQgetResult` to determine whether the server successfully created the prepared statement. The function's parameters are handled identically to `PQprepare`. Like `PQprepare`, it will not work on 2.0-protocol connections.

#### `PQsendQueryPrepared`

Sends a request to execute a prepared statement with given parameters, without waiting for the result(s).

```
int PQsendQueryPrepared(PGconn *conn,
                        const char *stmtName,
                        int nParams,
                        const char * const *paramValues,
                        const int *paramLengths,
                        const int *paramFormats,
                        int resultFormat);
```

This is similar to `PQsendQueryParams`, but the command to be executed is specified by naming a previously-prepared statement, instead of giving a query string. The function's parameters are handled identically to `PQexecPrepared`. Like `PQexecPrepared`, it will not work on 2.0-protocol connections.

#### `PQsendDescribePrepared`

Submits a request to obtain information about the specified prepared statement, without waiting for completion.

```
int PQsendDescribePrepared(PGconn *conn, const char *stmtName);
```

This is an asynchronous version of `PQdescribePrepared`: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call `PQgetResult` to obtain the results. The function's parameters are handled identically to `PQdescribePrepared`. Like `PQdescribePrepared`, it will not work on 2.0-protocol connections.

`PQsendDescribePortal`

Submits a request to obtain information about the specified portal, without waiting for completion.

```
int PQsendDescribePortal(PGconn *conn, const char *portalName);
```

This is an asynchronous version of `PQdescribePortal`: it returns 1 if it was able to dispatch the request, and 0 if not. After a successful call, call `PQgetResult` to obtain the results. The function's parameters are handled identically to `PQdescribePortal`. Like `PQdescribePortal`, it will not work on 2.0-protocol connections.

`PQgetResult`

Waits for the next result from a prior `PQsendQuery`, `PQsendQueryParams`, `PQsendPrepare`, or `PQsendQueryPrepared` call, and returns it. A null pointer is returned when the command is complete and there will be no more results.

```
PGresult *PQgetResult(PGconn *conn);
```

`PQgetResult` must be called repeatedly until it returns a null pointer, indicating that the command is done. (If called when no command is active, `PQgetResult` will just return a null pointer at once.) Each non-null result from `PQgetResult` should be processed using the same `PGresult` accessor functions previously described. Don't forget to free each result object with `PQclear` when done with it. Note that `PQgetResult` will block only if a command is active and the necessary response data has not yet been read by `PQconsumeInput`.

Using `PQsendQuery` and `PQgetResult` solves one of `PQexec`'s problems: If a command string contains multiple SQL commands, the results of those commands can be obtained individually. (This allows a simple form of overlapped processing, by the way: the client can be handling the results of one command while the server is still working on later queries in the same command string.) However, calling `PQgetResult` will still cause the client to block until the server completes the next SQL command. This can be avoided by proper use of two more functions:

`PQconsumeInput`

If input is available from the server, consume it.

```
int PQconsumeInput(PGconn *conn);
```

`PQconsumeInput` normally returns 1 indicating "no error", but returns 0 if there was some kind of trouble (in which case `PQerrorMessage` can be consulted). Note that the result does not say whether any input data was actually collected. After calling `PQconsumeInput`, the application can check `PQisBusy` and/or `PQnotifies` to see if their state has changed.

`PQconsumeInput` can be called even if the application is not prepared to deal with a result or notification just yet. The function will read available data and save it in a buffer, thereby causing a `select()` read-ready indication to go away. The application can thus use `PQconsumeInput` to clear the `select()` condition immediately, and then examine the results at leisure.

`PQisBusy`

Returns 1 if a command is busy, that is, `PQgetResult` would block waiting for input. A 0 return indicates that `PQgetResult` can be called with assurance of not blocking.

```
int PQisBusy(PGconn *conn);
```

`PQisBusy` will not itself attempt to read data from the server; therefore `PQconsumeInput` must be invoked first, or the busy state will never end.

A typical application using these functions will have a main loop that uses `select()` or `poll()` to wait for all the conditions that it must respond to. One of the conditions will be input available from the server, which in terms of `select()` means readable data on the file descriptor identified by `PQsocket`. When the main loop detects input ready, it should call `PQconsumeInput` to read the input. It can then call `PQisBusy`, followed by `PQgetResult` if `PQisBusy` returns false (0). It can also call `PQnotifies` to detect NOTIFY messages (see Section 30.7).

A client that uses `PQsendQuery/PQgetResult` can also attempt to cancel a command that is still being processed by the server; see Section 30.5. But regardless of the return value of `PQcancel`, the application must continue with the normal result-reading sequence using `PQgetResult`. A successful cancellation will simply cause the command to terminate sooner than it would have otherwise.

By using the functions described above, it is possible to avoid blocking while waiting for input from the database server. However, it is still possible that the application will block waiting to send output to the server. This is relatively uncommon but can happen if very long SQL commands or data values are sent. (It is much more probable if the application sends data via `COPY IN`, however.) To prevent this possibility and achieve completely nonblocking database operation, the following additional functions can be used.

`PQsetnonblocking`

Sets the nonblocking status of the connection.

```
int PQsetnonblocking(PGconn *conn, int arg);
```

Sets the state of the connection to nonblocking if `arg` is 1, or blocking if `arg` is 0. Returns 0 if OK, -1 if error.

In the nonblocking state, calls to `PQsendQuery`, `PQputline`, `PQputnbytes`, and `PQendcopy` will not block but instead return an error if they need to be called again.

Note that `PQexec` does not honor nonblocking mode; if it is called, it will act in blocking fashion anyway.

`PQisnonblocking`

Returns the blocking status of the database connection.

```
int PQisnonblocking(const PGconn *conn);
```

Returns 1 if the connection is set to nonblocking mode and 0 if blocking.

**PQflush**

Attempts to flush any queued output data to the server. Returns 0 if successful (or if the send queue is empty), -1 if it failed for some reason, or 1 if it was unable to send all the data in the send queue yet (this case can only occur if the connection is nonblocking).

```
int PQflush(PGconn *conn);
```

After sending any command or data on a nonblocking connection, call `PQflush`. If it returns 1, wait for the socket to be write-ready and call it again; repeat until it returns 0. Once `PQflush` returns 0, wait for the socket to be read-ready and then read the response as described above.

## 30.5. Cancelling Queries in Progress

A client application can request cancellation of a command that is still being processed by the server, using the functions described in this section.

**PQgetCancel**

Creates a data structure containing the information needed to cancel a command issued through a particular database connection.

```
PGcancel *PQgetCancel(PGconn *conn);
```

`PQgetCancel` creates a `PGcancel` object given a `PGconn` connection object. It will return `NULL` if the given `conn` is `NULL` or an invalid connection. The `PGcancel` object is an opaque structure that is not meant to be accessed directly by the application; it can only be passed to `PQcancel` or `PQfreeCancel`.

**PQfreeCancel**

Frees a data structure created by `PQgetCancel`.

```
void PQfreeCancel(PGcancel *cancel);
```

`PQfreeCancel` frees a data object previously created by `PQgetCancel`.

**PQcancel**

Requests that the server abandon processing of the current command.

```
int PQcancel(PGcancel *cancel, char *errbuf, int errbufsize);
```

The return value is 1 if the cancel request was successfully dispatched and 0 if not. If not, `errbuf` is filled with an error message explaining why not. `errbuf` must be a char array of size `errbufsize` (the recommended size is 256 bytes).

Successful dispatch is no guarantee that the request will have any effect, however. If the cancellation is effective, the current command will terminate early and return an error result. If the cancellation fails (say, because the server was already done processing the command), then there will be no visible result at all.

`PQcancel` can safely be invoked from a signal handler, if the `errbuf` is a local variable in the signal handler. The `PQcancel` object is read-only as far as `PQcancel` is concerned, so it can also be invoked from a thread that is separate from the one manipulating the `PGconn` object.

`PQrequestCancel`

Requests that the server abandon processing of the current command.

```
int PQrequestCancel(PGconn *conn);
```

`PQrequestCancel` is a deprecated variant of `PQcancel`. It operates directly on the `PGconn` object, and in case of failure stores the error message in the `PGconn` object (whence it can be retrieved by `PQerrorMessage`). Although the functionality is the same, this approach creates hazards for multiple-thread programs and signal handlers, since it is possible that overwriting the `PGconn`'s error message will mess up the operation currently in progress on the connection.

## 30.6. The Fast-Path Interface

PostgreSQL provides a fast-path interface to send simple function calls to the server.

**Tip:** This interface is somewhat obsolete, as one can achieve similar performance and greater functionality by setting up a prepared statement to define the function call. Then, executing the statement with binary transmission of parameters and results substitutes for a fast-path function call.

The function `PQfn` requests execution of a server function via the fast-path interface:

```
PGresult *PQfn(PGconn *conn,
               int fnid,
               int *result_buf,
               int *result_len,
               int result_is_int,
               const PQArgBlock *args,
               int nargs);

typedef struct {
    int len;
    int isint;
    union {
        int *ptr;
        int integer;
    } u;
} PQArgBlock;
```

The `fnid` argument is the OID of the function to be executed. `args` and `nargs` define the parameters to be passed to the function; they must match the declared function argument list. When the `isint` field

of a parameter structure is true, the `u.integer` value is sent to the server as an integer of the indicated length (this must be 1, 2, or 4 bytes); proper byte-swapping occurs. When `isint` is false, the indicated number of bytes at `*u.ptr` are sent with no processing; the data must be in the format expected by the server for binary transmission of the function's argument data type. `result_buf` is the buffer in which to place the return value. The caller must have allocated sufficient space to store the return value. (There is no check!) The actual result length will be returned in the integer pointed to by `result_len`. If a 1, 2, or 4-byte integer result is expected, set `result_is_int` to 1, otherwise set it to 0. Setting `result_is_int` to 1 causes libpq to byte-swap the value if necessary, so that it is delivered as a proper `int` value for the client machine. When `result_is_int` is 0, the binary-format byte string sent by the server is returned unmodified.

`PQfn` always returns a valid `PGresult` pointer. The result status should be checked before the result is used. The caller is responsible for freeing the `PGresult` with `PQclear` when it is no longer needed.

Note that it is not possible to handle null arguments, null results, nor set-valued results when using this interface.

## 30.7. Asynchronous Notification

PostgreSQL offers asynchronous notification via the `LISTEN` and `NOTIFY` commands. A client session registers its interest in a particular notification condition with the `LISTEN` command (and can stop listening with the `UNLISTEN` command). All sessions listening on a particular condition will be notified asynchronously when a `NOTIFY` command with that condition name is executed by any session. No additional information is passed from the notifier to the listener. Thus, typically, any actual data that needs to be communicated is transferred through a database table. Commonly, the condition name is the same as the associated table, but it is not necessary for there to be any associated table.

libpq applications submit `LISTEN` and `UNLISTEN` commands as ordinary SQL commands. The arrival of `NOTIFY` messages can subsequently be detected by calling `PQnotifies`.

The function `PQnotifies` returns the next notification from a list of unhandled notification messages received from the server. It returns a null pointer if there are no pending notifications. Once a notification is returned from `PQnotifies`, it is considered handled and will be removed from the list of notifications.

```
PGnotify *PQnotifies(PGconn *conn);

typedef struct pgNotify {
    char *relname;           /* notification condition name */
    int be_pid;              /* process ID of notifying server process */
    char *extra;             /* notification parameter */
} PGnotify;
```

After processing a `PGnotify` object returned by `PQnotifies`, be sure to free it with `PQfreemem`. It is sufficient to free the `PGnotify` pointer; the `relname` and `extra` fields do not represent separate allocations. (At present, the `extra` field is unused and will always point to an empty string.)

Example 30-2 gives a sample program that illustrates the use of asynchronous notification.

`PQnotifies` does not actually read data from the server; it just returns messages previously absorbed by another libpq function. In prior releases of libpq, the only way to ensure timely receipt of `NOTIFY`

messages was to constantly submit commands, even empty ones, and then check `PQnotifies` after each `PQexec`. While this still works, it is deprecated as a waste of processing power.

A better way to check for `NOTIFY` messages when you have no useful commands to execute is to call `PQconsumeInput`, then check `PQnotifies`. You can use `select()` to wait for data to arrive from the server, thereby using no CPU power unless there is something to do. (See `PQsocket` to obtain the file descriptor number to use with `select()`.) Note that this will work OK whether you submit commands with `PQsendQuery/PQgetResult` or simply use `PQexec`. You should, however, remember to check `PQnotifies` after each `PQgetResult` or `PQexec`, to see if any notifications came in during the processing of the command.

## 30.8. Functions Associated with the `COPY` Command

The `COPY` command in PostgreSQL has options to read from or write to the network connection used by libpq. The functions described in this section allow applications to take advantage of this capability by supplying or consuming copied data.

The overall process is that the application first issues the SQL `COPY` command via `PQexec` or one of the equivalent functions. The response to this (if there is no error in the command) will be a `PGresult` object bearing a status code of `PGRES_COPY_OUT` or `PGRES_COPY_IN` (depending on the specified copy direction). The application should then use the functions of this section to receive or transmit data rows. When the data transfer is complete, another `PGresult` object is returned to indicate success or failure of the transfer. Its status will be `PGRES_COMMAND_OK` for success or `PGRES_FATAL_ERROR` if some problem was encountered. At this point further SQL commands can be issued via `PQexec`. (It is not possible to execute other SQL commands using the same connection while the `COPY` operation is in progress.)

If a `COPY` command is issued via `PQexec` in a string that could contain additional commands, the application must continue fetching results via `PQgetResult` after completing the `COPY` sequence. Only when `PQgetResult` returns `NULL` is it certain that the `PQexec` command string is done and it is safe to issue more commands.

The functions of this section should be executed only after obtaining a result status of `PGRES_COPY_OUT` or `PGRES_COPY_IN` from `PQexec` or `PQgetResult`.

A `PGresult` object bearing one of these status values carries some additional data about the `COPY` operation that is starting. This additional data is available using functions that are also used in connection with query results:

`PQnfields`

Returns the number of columns (fields) to be copied.

`PQbinaryTuples`

0 indicates the overall copy format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary. See *COPY* for more information.

`PQffformat`

Returns the format code (0 for text, 1 for binary) associated with each column of the copy operation. The per-column format codes will always be zero when the overall copy format is textual, but the binary format can support both text and binary columns. (However, as of the current implementation

of `COPY`, only binary columns appear in a binary copy; so the per-column formats always match the overall format at present.)

**Note:** These additional data values are only available when using protocol 3.0. When using protocol 2.0, all these functions will return 0.

### 30.8.1. Functions for Sending `COPY` Data

These functions are used to send data during `COPY FROM STDIN`. They will fail if called when the connection is not in `COPY_IN` state.

`PQputCopyData`

Sends data to the server during `COPY_IN` state.

```
int PQputCopyData(PGconn *conn,
                  const char *buffer,
                  int nbytes);
```

Transmits the `COPY` data in the specified `buffer`, of length `nbytes`, to the server. The result is 1 if the data was sent, zero if it was not sent because the attempt would block (this case is only possible if the connection is in nonblocking mode), or -1 if an error occurred. (Use `PQerrorMessage` to retrieve details if the return value is -1. If the value is zero, wait for write-ready and try again.)

The application can divide the `COPY` data stream into buffer loads of any convenient size. Buffer-load boundaries have no semantic significance when sending. The contents of the data stream must match the data format expected by the `COPY` command; see *COPY* for details.

`PQputCopyEnd`

Sends end-of-data indication to the server during `COPY_IN` state.

```
int PQputCopyEnd(PGconn *conn,
                 const char *errmsg);
```

Ends the `COPY_IN` operation successfully if `errmsg` is NULL. If `errmsg` is not NULL then the `COPY` is forced to fail, with the string pointed to by `errmsg` used as the error message. (One should not assume that this exact error message will come back from the server, however, as the server might have already failed the `COPY` for its own reasons. Also note that the option to force failure does not work when using pre-3.0-protocol connections.)

The result is 1 if the termination data was sent, zero if it was not sent because the attempt would block (this case is only possible if the connection is in nonblocking mode), or -1 if an error occurred. (Use `PQerrorMessage` to retrieve details if the return value is -1. If the value is zero, wait for write-ready and try again.)

After successfully calling `PQputCopyEnd`, call `PQgetResult` to obtain the final result status of the `COPY` command. One can wait for this result to be available in the usual way. Then return to normal operation.

### 30.8.2. Functions for Receiving COPY Data

These functions are used to receive data during COPY TO STDOUT. They will fail if called when the connection is not in COPY\_OUT state.

PQgetCopyData

Receives data from the server during COPY\_OUT state.

```
int PQgetCopyData(PGconn *conn,
                  char **buffer,
                  int async);
```

Attempts to obtain another row of data from the server during a COPY. Data is always returned one data row at a time; if only a partial row is available, it is not returned. Successful return of a data row involves allocating a chunk of memory to hold the data. The `buffer` parameter must be non-NULL. `*buffer` is set to point to the allocated memory, or to NULL in cases where no buffer is returned. A non-NULL result buffer must be freed using `PQfreemem` when no longer needed.

When a row is successfully returned, the return value is the number of data bytes in the row (this will always be greater than zero). The returned string is always null-terminated, though this is probably only useful for textual COPY. A result of zero indicates that the COPY is still in progress, but no row is yet available (this is only possible when `async` is true). A result of -1 indicates that the COPY is done. A result of -2 indicates that an error occurred (consult `PQerrorMessage` for the reason).

When `async` is true (not zero), `PQgetCopyData` will not block waiting for input; it will return zero if the COPY is still in progress but no complete row is available. (In this case wait for read-ready and then call `PQconsumeInput` before calling `PQgetCopyData` again.) When `async` is false (zero), `PQgetCopyData` will block until data is available or the operation completes.

After `PQgetCopyData` returns -1, call `PQgetResult` to obtain the final result status of the COPY command. One can wait for this result to be available in the usual way. Then return to normal operation.

### 30.8.3. Obsolete Functions for COPY

These functions represent older methods of handling COPY. Although they still work, they are deprecated due to poor error handling, inconvenient methods of detecting end-of-data, and lack of support for binary or nonblocking transfers.

PQgetline

Reads a newline-terminated line of characters (transmitted by the server) into a buffer string of size `length`.

```
int PQgetline(PGconn *conn,
              char *buffer,
              int length);
```

This function copies up to `length-1` characters into the buffer and converts the terminating newline into a zero byte. `PQgetline` returns EOF at the end of input, 0 if the entire line has been read, and 1 if the buffer is full but the terminating newline has not yet been read.

Note that the application must check to see if a new line consists of the two characters `\.`, which indicates that the server has finished sending the results of the `COPY` command. If the application might receive lines that are more than `length-1` characters long, care is needed to be sure it recognizes the `\.` line correctly (and does not, for example, mistake the end of a long data line for a terminator line).

#### PQgetlineAsync

Reads a row of `COPY` data (transmitted by the server) into a buffer without blocking.

```
int PQgetlineAsync(PGconn *conn,
                  char *buffer,
                  int bufsize);
```

This function is similar to `PQgetline`, but it can be used by applications that must read `COPY` data asynchronously, that is, without blocking. Having issued the `COPY` command and gotten a `PGRES_COPY_OUT` response, the application should call `PQconsumeInput` and `PQgetlineAsync` until the end-of-data signal is detected.

Unlike `PQgetline`, this function takes responsibility for detecting end-of-data.

On each call, `PQgetlineAsync` will return data if a complete data row is available in libpq's input buffer. Otherwise, no data is returned until the rest of the row arrives. The function returns -1 if the end-of-copy-data marker has been recognized, or 0 if no data is available, or a positive number giving the number of bytes of data returned. If -1 is returned, the caller must next call `PQendcopy`, and then return to normal processing.

The data returned will not extend beyond a data-row boundary. If possible a whole row will be returned at one time. But if the buffer offered by the caller is too small to hold a row sent by the server, then a partial data row will be returned. With textual data this can be detected by testing whether the last returned byte is `\n` or not. (In a binary `COPY`, actual parsing of the `COPY` data format will be needed to make the equivalent determination.) The returned string is not null-terminated. (If you want to add a terminating null, be sure to pass a `bufsize` one smaller than the room actually available.)

#### PQputline

Sends a null-terminated string to the server. Returns 0 if OK and EOF if unable to send the string.

```
int PQputline(PGconn *conn,
              const char *string);
```

The `COPY` data stream sent by a series of calls to `PQputline` has the same format as that returned by `PQgetlineAsync`, except that applications are not obliged to send exactly one data row per `PQputline` call; it is okay to send a partial line or multiple lines per call.

**Note:** Before PostgreSQL protocol 3.0, it was necessary for the application to explicitly send the two characters `\.` as a final line to indicate to the server that it had finished sending `COPY` data. While this still works, it is deprecated and the special meaning of `\.` can be expected to be removed in a future release. It is sufficient to call `PQendcopy` after having sent the actual data.

**PQputnbytes**

Sends a non-null-terminated string to the server. Returns 0 if OK and EOF if unable to send the string.

```
int PQputnbytes(PGconn *conn,
               const char *buffer,
               int nbytes);
```

This is exactly like `PQputline`, except that the data buffer need not be null-terminated since the number of bytes to send is specified directly. Use this procedure when sending binary data.

**PQendcopy**

Synchronizes with the server.

```
int PQendcopy(PGconn *conn);
```

This function waits until the server has finished the copying. It should either be issued when the last string has been sent to the server using `PQputline` or when the last string has been received from the server using `PGgetline`. It must be issued or the server will get “out of sync” with the client. Upon return from this function, the server is ready to receive the next SQL command. The return value is 0 on successful completion, nonzero otherwise. (Use `PQerrorMessage` to retrieve details if the return value is nonzero.)

When using `PQgetResult`, the application should respond to a `PGRES_COPY_OUT` result by executing `PQgetline` repeatedly, followed by `PQendcopy` after the terminator line is seen. It should then return to the `PQgetResult` loop until `PQgetResult` returns a null pointer. Similarly a `PGRES_COPY_IN` result is processed by a series of `PQputline` calls followed by `PQendcopy`, then return to the `PQgetResult` loop. This arrangement will ensure that a `COPY` command embedded in a series of SQL commands will be executed correctly.

Older applications are likely to submit a `COPY` via `PQexec` and assume that the transaction is done after `PQendcopy`. This will work correctly only if the `COPY` is the only SQL command in the command string.

## 30.9. Control Functions

These functions control miscellaneous details of libpq’s behavior.

**PQclientEncoding**

Returns the client encoding.

```
int PQclientEncoding(const PGconn *conn);
```

Note that it returns the encoding ID, not a symbolic string such as `EUC_JP`. To convert an encoding ID to an encoding name, you can use:

```
char *pg_encoding_to_char(int encoding_id);
```

**PQsetClientEncoding**

Sets the client encoding.

```
int PQsetClientEncoding(PGconn *conn, const char *encoding);
```

*conn* is a connection to the server, and *encoding* is the encoding you want to use. If the function successfully sets the encoding, it returns 0, otherwise -1. The current encoding for this connection can be determined by using `PQclientEncoding`.

**PQsetErrorVerbosity**

Determines the verbosity of messages returned by `PQerrorMessage` and `PQresultErrorMessage`.

```
typedef enum {
    PQERRORS_TERSE,
    PQERRORS_DEFAULT,
    PQERRORS_VERBOSE
} PGVerbosity;
```

```
PGVerbosity PQsetErrorVerbosity(PGconn *conn, PGVerbosity verbosity);
```

`PQsetErrorVerbosity` sets the verbosity mode, returning the connection's previous setting. In *TERSE* mode, returned messages include severity, primary text, and position only; this will normally fit on a single line. The default mode produces messages that include the above plus any detail, hint, or context fields (these might span multiple lines). The *VERBOSE* mode includes all available fields. Changing the verbosity does not affect the messages available from already-existing `PGresult` objects, only subsequently-created ones.

**PQtrace**

Enables tracing of the client/server communication to a debugging file stream.

```
void PQtrace(PGconn *conn, FILE *stream);
```

**Note:** On Windows, if the libpq library and an application are compiled with different flags, this function call will crash the application because the internal representation of the `FILE` pointers differ. Specifically, multithreaded/single-threaded, release/debug, and static/dynamic flags should be the same for the library and all applications using that library.

**PQuntrace**

Disables tracing started by `PQtrace`.

```
void PQuntrace(PGconn *conn);
```

## 30.10. Miscellaneous Functions

As always, there are some functions that just don't fit anywhere.

PQencryptPassword

Prepares the encrypted form of a PostgreSQL password.

```
char * PQencryptPassword(const char *passwd, const char *user);
```

This function is intended to be used by client applications that wish to send commands like `ALTER USER joe PASSWORD 'pwd'`. It is good practice not to send the original cleartext password in such a command, because it might be exposed in command logs, activity displays, and so on. Instead, use this function to convert the password to encrypted form before it is sent. The arguments are the cleartext password, and the SQL name of the user it is for. The return value is a string allocated by `malloc`, or `NULL` if out of memory. The caller can assume the string doesn't contain any special characters that would require escaping. Use `PQfreemem` to free the result when done with it.

## 30.11. Notice Processing

Notice and warning messages generated by the server are not returned by the query execution functions, since they do not imply failure of the query. Instead they are passed to a notice handling function, and execution continues normally after the handler returns. The default notice handling function prints the message on `stderr`, but the application can override this behavior by supplying its own handling function.

For historical reasons, there are two levels of notice handling, called the notice receiver and notice processor. The default behavior is for the notice receiver to format the notice and pass a string to the notice processor for printing. However, an application that chooses to provide its own notice receiver will typically ignore the notice processor layer and just do all the work in the notice receiver.

The function `PQsetNoticeReceiver` sets or examines the current notice receiver for a connection object. Similarly, `PQsetNoticeProcessor` sets or examines the current notice processor.

```
typedef void (*PQnoticeReceiver) (void *arg, const PGresult *res);

PQnoticeReceiver
PQsetNoticeReceiver(PGconn *conn,
                   PQnoticeReceiver proc,
                   void *arg);

typedef void (*PQnoticeProcessor) (void *arg, const char *message);

PQnoticeProcessor
PQsetNoticeProcessor(PGconn *conn,
                   PQnoticeProcessor proc,
                   void *arg);
```

Each of these functions returns the previous notice receiver or processor function pointer, and sets the new value. If you supply a null function pointer, no action is taken, but the current pointer is returned.

When a notice or warning message is received from the server, or generated internally by libpq, the notice receiver function is called. It is passed the message in the form of a `PGRES_NONFATAL_ERROR PGresult`. (This allows the receiver to extract individual fields using `PQresultErrorField`, or the complete preformatted message using `PQresultErrorMessage`.) The same void pointer passed to

`PQsetNoticeReceiver` is also passed. (This pointer can be used to access application-specific state if needed.)

The default notice receiver simply extracts the message (using `PQresultErrorMessage`) and passes it to the notice processor.

The notice processor is responsible for handling a notice or warning message given in text form. It is passed the string text of the message (including a trailing newline), plus a void pointer that is the same one passed to `PQsetNoticeProcessor`. (This pointer can be used to access application-specific state if needed.)

The default notice processor is simply:

```
static void
defaultNoticeProcessor(void *arg, const char *message)
{
    fprintf(stderr, "%s", message);
}
```

Once you have set a notice receiver or processor, you should expect that that function could be called as long as either the `PGconn` object or `PGresult` objects made from it exist. At creation of a `PGresult`, the `PGconn`'s current notice handling pointers are copied into the `PGresult` for possible use by functions like `PQgetvalue`.

## 30.12. Environment Variables

The following environment variables can be used to select default connection parameter values, which will be used by `PQconnectdb`, `PQsetdbLogin` and `PQsetdb` if no value is directly specified by the calling code. These are useful to avoid hard-coding database connection information into simple client applications, for example.

- `PGHOST` sets the database server name. If this begins with a slash, it specifies Unix-domain communication rather than TCP/IP communication; the value is then the name of the directory in which the socket file is stored (in a default installation setup this would be `/tmp`).
- `PGHOSTADDR` specifies the numeric IP address of the database server. This can be set instead of or in addition to `PGHOST` to avoid DNS lookup overhead. See the documentation of these parameters, under `PQconnectdb` above, for details on their interaction.

When neither `PGHOST` nor `PGHOSTADDR` is set, the default behavior is to connect using a local Unix-domain socket; or on machines without Unix-domain sockets, libpq will attempt to connect to `localhost`.

- `PGPORT` sets the TCP port number or Unix-domain socket file extension for communicating with the PostgreSQL server.
- `PGDATABASE` sets the PostgreSQL database name.
- `PGUSER` sets the user name used to connect to the database.

- `PGPASSWORD` sets the password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via `ps`); instead consider using the `~/.pgpass` file (see Section 30.13).
- `PGPASSFILE` specifies the name of the password file to use for lookups. If not set, it defaults to `~/.pgpass` (see Section 30.13).
- `PGSERVICE` sets the service name to be looked up in `pg_service.conf`. This offers a shorthand way of setting all the parameters.
- `PGREALM` sets the Kerberos realm to use with PostgreSQL, if it is different from the local realm. If `PGREALM` is set, libpq applications will attempt authentication with servers for this realm and use separate ticket files to avoid conflicts with local ticket files. This environment variable is only used if Kerberos authentication is selected by the server.
- `PGOPTIONS` sets additional run-time options for the PostgreSQL server.
- `PGSSLMODE` determines whether and with what priority an SSL connection will be negotiated with the server. There are four modes: `disable` will attempt only an unencrypted SSL connection; `allow` will negotiate, trying first a non-SSL connection, then if that fails, trying an SSL connection; `prefer` (the default) will negotiate, trying first an SSL connection, then if that fails, trying a regular non-SSL connection; `require` will try only an SSL connection. If PostgreSQL is compiled without SSL support, using option `require` will cause an error, while options `allow` and `prefer` will be accepted but libpq will not in fact attempt an SSL connection.
- `PGREQUIRESSL` sets whether or not the connection must be made over SSL. If set to “1”, libpq will refuse to connect if the server does not accept an SSL connection (equivalent to `sslmode prefer`). This option is deprecated in favor of the `sslmode` setting, and is only available if PostgreSQL is compiled with SSL support.
- `PGSSLKEY` specifies the hardware token that stores the secret key for the client certificate. The value of this variable should consist of a colon-separated engine name (engines are OpenSSL loadable modules) and an engine-specific key identifier. If this is not set, the secret key must be kept in a file.
- `PGKRBSRVNAME` sets the Kerberos service name to use when authenticating with Kerberos 5 or GSS-API.
- `PGGSSLIB` sets the GSS library to use for GSSAPI authentication.
- `PGCONNECT_TIMEOUT` sets the maximum number of seconds that libpq will wait when attempting to connect to the PostgreSQL server. If unset or set to zero, libpq will wait indefinitely. It is not recommended to set the timeout to less than 2 seconds.

The following environment variables can be used to specify default behavior for each PostgreSQL session. (See also the `ALTER USER` and `ALTER DATABASE` commands for ways to set default behavior on a per-user or per-database basis.)

- `PGDATESTYLE` sets the default style of date/time representation. (Equivalent to `SET datestyle TO ...`.)
- `PGTZ` sets the default time zone. (Equivalent to `SET timezone TO ...`.)

- `PGCLIENTENCODING` sets the default client character set encoding. (Equivalent to `SET client_encoding TO ...`)
- `PGGEQO` sets the default mode for the genetic query optimizer. (Equivalent to `SET geqo TO ...`)

Refer to the SQL command *SET* for information on correct values for these environment variables.

The following environment variables determine internal behavior of libpq; they override compiled-in defaults.

- `PGSYSCONFDIR` sets the directory containing the `pg_service.conf` file.
- `PGLOCALEDIR` sets the directory containing the `locale` files for message internationalization.

## 30.13. The Password File

The file `.pgpass` in a user's home directory or the file referenced by `PGPASSFILE` can contain passwords to be used if the connection requires a password (and no password has been specified otherwise). On Microsoft Windows the file is named `%APPDATA%\postgresql\pgpass.conf` (where `%APPDATA%` refers to the Application Data subdirectory in the user's profile).

This file should contain lines of the following format:

```
hostname:port:database:username:password
```

Each of the first four fields can be a literal value, or `*`, which matches anything. The password field from the first line that matches the current connection parameters will be used. (Therefore, put more-specific entries first when you are using wildcards.) If an entry needs to contain `:` or `\`, escape this character with `\`. A host name of `localhost` matches both TCP (host name `localhost`) and Unix domain socket (`pghost` empty or the default socket directory) connections coming from the local machine.

On Unix systems, the permissions on `.pgpass` must disallow any access to world or group; achieve this by the command `chmod 0600 ~/.pgpass`. If the permissions are less strict than this, the file will be ignored. On Microsoft Windows, it is assumed that the file is stored in a directory that is secure, so no special permissions check is made.

## 30.14. The Connection Service File

The connection service file allows libpq connection parameters to be associated with a single service name. That service name can then be specified by a libpq connection, and the associated settings will be used. This allows connection parameters to be modified without requiring a recompile of the libpq application. The service name can also be specified using the `PGSERVICE` environment variable.

To use this feature, copy `share/pg_service.conf.sample` to `etc/pg_service.conf` and edit the file to add service names and parameters. This file can be used for client-only installs too. The file's location can also be specified by the `PGSYSCONFDIR` environment variable.

## 30.15. LDAP Lookup of Connection Parameters

If libpq has been compiled with LDAP support (option `--with-ldap` for `configure`) it is possible to retrieve connection options like `host` or `dbname` via LDAP from a central server. The advantage is that if the connection parameters for a database change, the connection information doesn't have to be updated on all client machines.

LDAP connection parameter lookup uses the connection service file `pg_service.conf` (see Section 30.14). A line in a `pg_service.conf` stanza that starts with `ldap://` will be recognized as an LDAP URL and an LDAP query will be performed. The result must be a list of `keyword = value` pairs which will be used to set connection options. The URL must conform to RFC 1959 and be of the form

```
ldap://[hostname[:port]]/search_base?attribute?search_scope?filter
```

where `hostname` defaults to `localhost` and `port` defaults to 389.

Processing of `pg_service.conf` is terminated after a successful LDAP lookup, but is continued if the LDAP server cannot be contacted. This is to provide a fallback with further LDAP URL lines that point to different LDAP servers, classical `keyword = value` pairs, or default connection options. If you would rather get an error message in this case, add a syntactically incorrect line after the LDAP URL.

A sample LDAP entry that has been created with the LDIF file

```
version:1
dn:cn=mydatabase,dc=mycompany,dc=com
changetype:add
objectclass:top
objectclass:groupOfUniqueNames
cn:mydatabase
uniqueMember:host=dbserver.mycompany.com
uniqueMember:port=5439
uniqueMember:dbname=mydb
uniqueMember:user=mydb_user
uniqueMember:sslmode=require
```

might be queried with the following LDAP URL:

```
ldap://ldap.mycompany.com/dc=mycompany,dc=com?uniqueMember?one?(cn=mydatabase)
```

You can also mix regular service file entries with LDAP lookups. A complete example for a stanza in `pg_service.conf` would be:

```
# only host and port are stored in LDAP, specify dbname and user explicitly
[customerdb]
dbname=customer
user=appuser
ldap://ldap.acme.com/cn=dbserver,cn=hosts?pgconnectinfo?base?(objectclass=*)
```

## 30.16. SSL Support

PostgreSQL has native support for using SSL connections to encrypt client/server communications for increased security. See Section 17.8 for details about the server-side SSL functionality.

libpq reads the system-wide OpenSSL configuration file. By default, this file is named `openssl.cnf` and is located in the directory reported by `openssl version -d`. This default can be overridden by setting environment variable `OPENSSL_CONF` to the name of the desired configuration file.

To verify the server certificate is trustworthy, place certificates of the certificate authorities (CA) you trust in the file `~/.postgresql/root.crt` in the user's home directory. (On Microsoft Windows the file is named `%APPDATA%\postgresql\root.crt`.) libpq will then verify that the server's certificate is signed by one of the trusted certificate authorities. The SSL connection will fail if the server does not present a trusted certificate. Certificate Revocation List (CRL) entries are also checked if the file `~/.postgresql/root.crl` exists (`%APPDATA%\postgresql\root.crl` on Microsoft Windows).

If the server requests a trusted client certificate, libpq will send the certificate stored in file `~/.postgresql/postgresql.crt` in the user's home directory. The certificate must be signed by one of the certificate authorities (CA) trusted by the server. A matching private key file `~/.postgresql/postgresql.key` must also be present, unless the secret key for the certificate is stored in a hardware token, as specified by `PGSSLKEY`. (On Microsoft Windows these files are named `%APPDATA%\postgresql\postgresql.crt` and `%APPDATA%\postgresql\postgresql.key`.) The private key file must not be world-readable.

If the environment variable `PGSSLKEY` is set, its value should consist of a colon-separated engine name and key identifier. In this case, libpq will load the specified engine, i.e. the OpenSSL module which supports special hardware, and reference the key with the specified identifier. Identifiers are engine-specific. Typically, cryptography hardware tokens do not reveal secret keys to the application. Instead, applications delegate all cryptography operations which require the secret key to the hardware token.

If you are using SSL inside your application (in addition to inside libpq), you can use `PQinitSSL(int)` to tell libpq that the SSL library has already been initialized by your application. See [http://h71000.www7.hp.com/doc/83final/BA554\\_90007/ch04.html](http://h71000.www7.hp.com/doc/83final/BA554_90007/ch04.html) for details on the SSL API.

**Table 30-1. Libpq/Client SSL File Usage**

File	Contents	Effect
<code>~/.postgresql/postgresql.crt</code>	client certificate	requested by server
<code>~/.postgresql/postgresql.key</code>	client private key	proves client certificate sent by owner; does not indicate certificate owner is trustworthy
<code>~/.postgresql/root.crt</code>	trusted certificate authorities	checks server certificate is signed by a trusted certificate authority
<code>~/.postgresql/root.crl</code>	certificates revoked by certificate authorities	server certificate must not be on this list

## 30.17. Behavior in Threaded Programs

libpq is reentrant and thread-safe if the `configure` command-line option `--enable-thread-safety` was used when the PostgreSQL distribution was built. In addition, you might need to use additional compiler command-line options when you compile your application code. Refer to your system's documentation for information about how to build thread-enabled applications, or look in `src/Makefile.global` for `PTHREAD_CFLAGS` and `PTHREAD_LIBS`. This function allows the querying of libpq's thread-safe status:

`PQisthreadsafe`

Returns the thread safety status of the libpq library.

```
int PQisthreadsafe();
```

Returns 1 if the libpq is thread-safe and 0 if it is not.

One thread restriction is that no two threads attempt to manipulate the same `PGconn` object at the same time. In particular, you cannot issue concurrent commands from different threads through the same connection object. (If you need to run concurrent commands, use multiple connections.)

`PGresult` objects are read-only after creation, and so can be passed around freely between threads.

The deprecated functions `PQrequestCancel` and `PQoidStatus` are not thread-safe and should not be used in multithread programs. `PQrequestCancel` can be replaced by `PQcancel`. `PQoidStatus` can be replaced by `PQoidValue`.

If you are using Kerberos inside your application (in addition to inside libpq), you will need to do locking around Kerberos calls because Kerberos functions are not thread-safe. See function `PQregisterThreadLock` in the libpq source code for a way to do cooperative locking between libpq and your application.

If you experience problems with threaded applications, run the program in `src/tools/thread` to see if your platform has thread-unsafe functions. This program is run by `configure`, but for binary distributions your library might not match the library used to build the binaries.

## 30.18. Building libpq Programs

To build (i.e., compile and link) a program using libpq you need to do all of the following things:

- Include the `libpq-fe.h` header file:

```
#include <libpq-fe.h>
```

If you failed to do that then you will normally get error messages from your compiler similar to

```
foo.c: In function 'main':
foo.c:34: 'PGconn' undeclared (first use in this function)
foo.c:35: 'PGresult' undeclared (first use in this function)
foo.c:54: 'CONNECTION_BAD' undeclared (first use in this function)
foo.c:68: 'PGRES_COMMAND_OK' undeclared (first use in this function)
foo.c:95: 'PGRES_TUPLES_OK' undeclared (first use in this function)
```

- Point your compiler to the directory where the PostgreSQL header files were installed, by supplying the `-I`*directory* option to your compiler. (In some cases the compiler will look into the directory in question by default, so you can omit this option.) For instance, your compile command line could look like:

```
cc -c -I/usr/local/pgsql/include testprog.c
```

If you are using makefiles then add the option to the `CPPFLAGS` variable:

```
CPPFLAGS += -I/usr/local/pgsql/include
```

If there is any chance that your program might be compiled by other users then you should not hardcode the directory location like that. Instead, you can run the utility `pg_config` to find out where the header files are on the local system:

```
$ pg_config --includedir
/usr/local/include
```

Failure to specify the correct option to the compiler will result in an error message such as

```
testlibpq.c:8:22: libpq-fe.h: No such file or directory
```

- When linking the final program, specify the option `-lpq` so that the `libpq` library gets pulled in, as well as the option `-L`*directory* to point the compiler to the directory where the `libpq` library resides. (Again, the compiler will search some directories by default.) For maximum portability, put the `-L` option before the `-lpq` option. For example:

```
cc -o testprog testprog1.o testprog2.o -L/usr/local/pgsql/lib -lpq
```

You can find out the library directory using `pg_config` as well:

```
$ pg_config --libdir
/usr/local/pgsql/lib
```

Error messages that point to problems in this area could look like the following.

```
testlibpq.o: In function 'main':
testlibpq.o(.text+0x60): undefined reference to 'PQsetdbLogin'
testlibpq.o(.text+0x71): undefined reference to 'PQstatus'
testlibpq.o(.text+0xa4): undefined reference to 'PQerrorMessage'
```

This means you forgot `-lpq`.

```
/usr/bin/ld: cannot find -lpq
```

This means you forgot the `-L` option or did not specify the right directory.

## 30.19. Example Programs

These examples and others can be found in the directory `src/test/examples` in the source code distribution.

### Example 30-1. libpq Example Program 1

```
/*
 * testlibpq.c
 *
 *      Test the C version of libpq, the PostgreSQL frontend library.
```

```

    */
#include <stdio.h>
#include <stdlib.h>
#include "libpq-fe.h"

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    const char *conninfo;
    PGconn      *conn;
    PGresult     *res;
    int          nFields;
    int          i,
                j;

    /*
     * If the user supplies a parameter on the command line, use it as the
     * conninfo string; otherwise default to setting dbname=postgres and using
     * environment variables or defaults for all other connection parameters.
     */
    if (argc > 1)
        conninfo = argv[1];
    else
        conninfo = "dbname = postgres";

    /* Make a connection to the database */
    conn = PQconnectdb(conninfo);

    /* Check to see that the backend connection was successfully made */
    if (PQstatus(conn) != CONNECTION_OK)
    {
        fprintf(stderr, "Connection to database failed: %s",
                PQerrorMessage(conn));
        exit_nicely(conn);
    }

    /*
     * Our test case here involves using a cursor, for which we must be inside
     * a transaction block. We could do the whole thing with a single
     * PQexec() of "select * from pg_database", but that's too trivial to make
     * a good example.
     */

    /* Start a transaction block */
    res = PQexec(conn, "BEGIN");
    if (PQresultStatus(res) != PGRES_COMMAND_OK)

```

```

{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * Should PQclear PGresult whenever it is no longer needed to avoid memory
 * leaks
 */
PQclear(res);

/*
 * Fetch rows from pg_database, the system catalog of databases
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* first, print out the attribute names */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* next, print out the rows */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

PQclear(res);

/* close the portal ... we don't bother to check for errors ... */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* end the transaction */

```

```

    res = PQexec(conn, "END");
    PQclear(res);

    /* close the connection to the database and cleanup */
    PQfinish(conn);

    return 0;
}

```

### Example 30-2. libpq Example Program 2

```

/*
 * testlibpq2.c
 *      Test of the asynchronous notification interface
 *
 * Start this program, then from psql in another window do
 *   NOTIFY TBL2;
 * Repeat four times to get this program to exit.
 *
 * Or, if you want to get fancy, try this:
 * populate a database with the following commands
 * (provided in src/test/examples/testlibpq2.sql):
 *
 *   CREATE TABLE TBL1 (i int4);
 *
 *   CREATE TABLE TBL2 (i int4);
 *
 *   CREATE RULE r1 AS ON INSERT TO TBL1 DO
 *       (INSERT INTO TBL2 VALUES (new.i); NOTIFY TBL2);
 *
 * and do this four times:
 *
 *   INSERT INTO TBL1 VALUES (10);
 */
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <errno.h>
#include <sys/time.h>
#include "libpq-fe.h"

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    const char *conninfo;

```

```

PGconn      *conn;
PGresult     *res;
PGnotify     *notify;
int          nnotifies;

/*
 * If the user supplies a parameter on the command line, use it as the
 * conninfo string; otherwise default to setting dbname=postgres and using
 * environment variables or defaults for all other connection parameters.
 */
if (argc > 1)
    conninfo = argv[1];
else
    conninfo = "dbname = postgres";

/* Make a connection to the database */
conn = PQconnectdb(conninfo);

/* Check to see that the backend connection was successfully made */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    exit_nicely(conn);
}

/*
 * Issue LISTEN command to enable notifications from the rule's NOTIFY.
 */
res = PQexec(conn, "LISTEN TBL2");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "LISTEN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * should PQclear PGresult whenever it is no longer needed to avoid memory
 * leaks
 */
PQclear(res);

/* Quit after four notifies are received. */
nnotifies = 0;
while (nnotifies < 4)
{
    /*
     * Sleep until something happens on the connection. We use select(2)
     * to wait for input, but you could also use poll() or similar
     * facilities.
     */
    int          sock;

```

```

    fd_set      input_mask;

    sock = PQsocket(conn);

        break;                /* shouldn't happen */

    FD_ZERO(&input_mask);
    FD_SET(sock, &input_mask);

    if (select(sock + 1, &input_mask, NULL, NULL, NULL) < 0)
    {
        fprintf(stderr, "select() failed: %s\n", strerror(errno));
        exit_nicely(conn);
    }

    /* Now check for input */
    PQconsumeInput(conn);
    while ((notify = PQnotifies(conn)) != NULL)
    {
        fprintf(stderr,
            "ASYNC NOTIFY of '%s' received from backend pid %d\n",
            notify->relname, notify->be_pid);
        PQfreemem(notify);
        nnotifies++;
    }
}

fprintf(stderr, "Done.\n");

/* close the connection to the database and cleanup */
PQfinish(conn);

return 0;
}

```

### Example 30-3. libpq Example Program 3

```

/*
 * testlibpq3.c
 *      Test out-of-line parameters and binary I/O.
 *
 * Before running this, populate a database with the following commands
 * (provided in src/test/examples/testlibpq3.sql):
 *
 * CREATE TABLE test1 (i int4, t text, b bytea);
 *
 * INSERT INTO test1 values (1, 'joe"s place', '\\000\\001\\002\\003\\004');
 * INSERT INTO test1 values (2, 'ho there', '\\004\\003\\002\\001\\000');
 *
 * The expected output is:
 *

```

```

* tuple 0: got
* i = (4 bytes) 1
* t = (11 bytes) 'joe's place'
* b = (5 bytes) \000\001\002\003\004
*
* tuple 0: got
* i = (4 bytes) 2
* t = (8 bytes) 'ho there'
* b = (5 bytes) \004\003\002\001\000
*/
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include "libpq-fe.h"

/* for ntohs/htons */
#include <netinet/in.h>
#include <arpa/inet.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

/*
 * This function prints a query result that is a binary-format fetch from
 * a table defined as in the comment above. We split it out because the
 * main() function uses it twice.
 */
static void
show_binary_results(PGresult *res)
{
    int          i,
                j;
    int          i_fnum,
                t_fnum,
                b_fnum;

    /* Use PQfnumber to avoid assumptions about field order in result */
    i_fnum = PQfnumber(res, "i");
    t_fnum = PQfnumber(res, "t");
    b_fnum = PQfnumber(res, "b");

}

```

# Chapter 31. Large Objects

PostgreSQL has a *large object* facility, which provides stream-style access to user data that is stored in a special large-object structure. Streaming access is useful when working with data values that are too large to manipulate conveniently as a whole.

This chapter describes the implementation and the programming and query language interfaces to PostgreSQL large object data. We use the libpq C library for the examples in this chapter, but most programming interfaces native to PostgreSQL support equivalent functionality. Other interfaces might use the large object interface internally to provide generic support for large values. This is not described here.

## 31.1. Introduction

All large objects are placed in a single system table called `pg_largeobject`. PostgreSQL also supports a storage system called “TOAST” that automatically stores values larger than a single database page into a secondary storage area per table. This makes the large object facility partially obsolete. One remaining advantage of the large object facility is that it allows values up to 2 GB in size, whereas TOASTed fields can be at most 1 GB. Also, large objects can be randomly modified using a read/write API that is more efficient than performing such operations using TOAST.

## 31.2. Implementation Features

The large object implementation breaks large objects up into “chunks” and stores the chunks in rows in the database. A B-tree index guarantees fast searches for the correct chunk number when doing random access reads and writes.

## 31.3. Client Interfaces

This section describes the facilities that PostgreSQL client interface libraries provide for accessing large objects. All large object manipulation using these functions *must* take place within an SQL transaction block. The PostgreSQL large object interface is modeled after the Unix file-system interface, with analogues of `open`, `read`, `write`, `lseek`, etc.

Client applications which use the large object interface in libpq should include the header file `libpq/libpq-fs.h` and link with the libpq library.

### 31.3.1. Creating a Large Object

The function

```
Oid lo_creat(PGconn *conn, int mode);
```

creates a new large object. The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure. *mode* is unused and ignored as of PostgreSQL 8.1; however, for back-

wards compatibility with earlier releases it is best to set it to `INV_READ`, `INV_WRITE`, or `INV_READ | INV_WRITE`. (These symbolic constants are defined in the header file `libpq/libpq-fs.h`.)

An example:

```
inv_oid = lo_creat(conn, INV_READ|INV_WRITE);
```

The function

```
Oid lo_create(PGconn *conn, Oid lobjId);
```

also creates a new large object. The OID to be assigned can be specified by *lobjId*; if so, failure occurs if that OID is already in use for some large object. If *lobjId* is `InvalidOid` (zero) then `lo_create` assigns an unused OID (this is the same behavior as `lo_creat`). The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure.

`lo_create` is new as of PostgreSQL 8.1; if this function is run against an older server version, it will fail and return `InvalidOid`.

An example:

```
inv_oid = lo_create(conn, desired_oid);
```

### 31.3.2. Importing a Large Object

To import an operating system file as a large object, call

```
Oid lo_import(PGconn *conn, const char *filename);
```

*filename* specifies the operating system name of the file to be imported as a large object. The return value is the OID that was assigned to the new large object, or `InvalidOid` (zero) on failure. Note that the file is read by the client interface library, not by the server; so it must exist in the client file system and be readable by the client application.

### 31.3.3. Exporting a Large Object

To export a large object into an operating system file, call

```
int lo_export(PGconn *conn, Oid lobjId, const char *filename);
```

The *lobjId* argument specifies the OID of the large object to export and the *filename* argument specifies the operating system name of the file. Note that the file is written by the client interface library, not by the server. Returns 1 on success, -1 on failure.

### 31.3.4. Opening an Existing Large Object

To open an existing large object for reading or writing, call

```
int lo_open(PGconn *conn, Oid lobjId, int mode);
```

The `lobjId` argument specifies the OID of the large object to open. The `mode` bits control whether the object is opened for reading (`INV_READ`), writing (`INV_WRITE`), or both. (These symbolic constants are defined in the header file `libpq/libpq-fs.h`.) A large object cannot be opened before it is created. `lo_open` returns a (non-negative) large object descriptor for later use in `lo_read`, `lo_write`, `lo_lseek`, `lo_tell`, and `lo_close`. The descriptor is only valid for the duration of the current transaction. On failure, `-1` is returned.

The server currently does not distinguish between modes `INV_WRITE` and `INV_READ | INV_WRITE`: you are allowed to read from the descriptor in either case. However there is a significant difference between these modes and `INV_READ` alone: with `INV_READ` you cannot write on the descriptor, and the data read from it will reflect the contents of the large object at the time of the transaction snapshot that was active when `lo_open` was executed, regardless of later writes by this or other transactions. Reading from a descriptor opened with `INV_WRITE` returns data that reflects all writes of other committed transactions as well as writes of the current transaction. This is similar to the behavior of `SERIALIZABLE` versus `READ COMMITTED` transaction modes for ordinary SQL `SELECT` commands.

An example:

```
inv_fd = lo_open(conn, inv_oid, INV_READ|INV_WRITE);
```

### 31.3.5. Writing Data to a Large Object

The function

```
int lo_write(PGconn *conn, int fd, const char *buf, size_t len);
```

writes `len` bytes from `buf` to large object descriptor `fd`. The `fd` argument must have been returned by a previous `lo_open`. The number of bytes actually written is returned. In the event of an error, the return value is negative.

### 31.3.6. Reading Data from a Large Object

The function

```
int lo_read(PGconn *conn, int fd, char *buf, size_t len);
```

reads `len` bytes from large object descriptor `fd` into `buf`. The `fd` argument must have been returned by a previous `lo_open`. The number of bytes actually read is returned. In the event of an error, the return value is negative.

### 31.3.7. Seeking in a Large Object

To change the current read or write location associated with a large object descriptor, call

```
int lo_lseek(PGconn *conn, int fd, int offset, int whence);
```

This function moves the current location pointer for the large object descriptor identified by `fd` to the new location specified by `offset`. The valid values for `whence` are `SEEK_SET` (seek from object start), `SEEK_CUR` (seek from current position), and `SEEK_END` (seek from object end). The return value is the new location pointer, or -1 on error.

### 31.3.8. Obtaining the Seek Position of a Large Object

To obtain the current read or write location of a large object descriptor, call

```
int lo_tell(PGconn *conn, int fd);
```

If there is an error, the return value is negative.

### 31.3.9. Truncating a Large Object

To truncate a large object to a given length, call

```
int lo_truncate(PGconn *conn, int fd, size_t len);
```

truncates the large object descriptor `fd` to length `len`. The `fd` argument must have been returned by a previous `lo_open`. If `len` is greater than the current large object length, the large object is extended with null bytes ('\0').

The file offset is not changed.

On success `lo_truncate` returns zero. On error, the return value is negative.

`lo_truncate` is new as of PostgreSQL 8.3; if this function is run against an older server version, it will fail and return a negative value.

### 31.3.10. Closing a Large Object Descriptor

A large object descriptor can be closed by calling

```
int lo_close(PGconn *conn, int fd);
```

where `fd` is a large object descriptor returned by `lo_open`. On success, `lo_close` returns zero. On error, the return value is negative.

Any large object descriptors that remain open at the end of a transaction will be closed automatically.

### 31.3.11. Removing a Large Object

To remove a large object from the database, call

```
int lo_unlink(PGconn *conn, Oid lobjId);
```

The `lobjId` argument specifies the OID of the large object to remove. Returns 1 if successful, -1 on failure.

## 31.4. Server-Side Functions

There are server-side functions callable from SQL that correspond to each of the client-side functions described above; indeed, for the most part the client-side functions are simply interfaces to the equivalent server-side functions. The ones that are actually useful to call via SQL commands are `lo_creat`, `lo_create`, `lo_unlink`, `lo_import`, and `lo_export`. Here are examples of their use:

```
CREATE TABLE image (
    name          text,
    raster        oid
);

SELECT lo_creat(-1);          -- returns OID of new, empty large object

SELECT lo_create(43213);     -- attempts to create large object with OID 43213

SELECT lo_unlink(173454);    -- deletes large object with OID 173454

INSERT INTO image (name, raster)
VALUES ('beautiful image', lo_import('/etc/motd'));

SELECT lo_export(image.raster, '/tmp/motd') FROM image
WHERE name = 'beautiful image';
```

The server-side `lo_import` and `lo_export` functions behave considerably differently from their client-side analogs. These two functions read and write files in the server's file system, using the permissions of the database's owning user. Therefore, their use is restricted to superusers. In contrast, the client-side import and export functions read and write files in the client's file system, using the permissions of the client program. The client-side functions can be used by any PostgreSQL user.

## 31.5. Example Program

Example 31-1 is a sample program which shows how the large object interface in `libpq` can be used. Parts of the program are commented out but are left in the source for the reader's benefit. This program can also be found in `src/test/examples/testlo.c` in the source distribution.

**Example 31-1. Large Objects with libpq Example Program**

```

/*-----

# Chapter 32. ECPG - Embedded SQL in C

This chapter describes the embedded SQL package for PostgreSQL. It was written by Linus Tolke (<linus@epact.se>) and Michael Meskes (<meskes@postgresql.org>). Originally it was written to work with C. It also works with C++, but it does not recognize all C++ constructs yet.

This documentation is quite incomplete. But since this interface is standardized, additional information can be found in many resources about SQL.

## 32.1. The Concept

An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program, and afterwards it can be processed by a C compiler.

Embedded SQL has advantages over other methods for handling SQL commands from C code. First, it takes care of the tedious passing of information to and from variables in your C program. Second, the SQL code in the program is checked at build time for syntactical correctness. Third, embedded SQL in C is specified in the SQL standard and supported by many other SQL database systems. The PostgreSQL implementation is designed to match this standard as much as possible, and it is usually possible to port embedded SQL programs written for other SQL databases to PostgreSQL with relative ease.

As already stated, programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...;
```

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and not those of C.

The following sections explain all the embedded SQL statements.

## 32.2. Connecting to the Database Server

One connects to a database using the following statement:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The *target* can be specified in the following ways:

- *dbname*[@*hostname*][:*port*]
- *tcp:postgresql://hostname[:port][/*dbname*][?*options*]*
- *unix:postgresql://hostname[:port][/*dbname*][?*options*]*

- an SQL string literal containing one of the above forms
- a reference to a character variable containing one of the above forms (see examples)
- `DEFAULT`

If you specify the connection target literally (that is, not through a variable reference) and you don't quote the value, then the case-insensitivity rules of normal SQL are applied. In that case you can also double-quote the individual parameters separately as needed. In practice, it is probably less error-prone to use a (single-quoted) string literal or a variable reference. The connection target `DEFAULT` initiates a connection to the default database under the default user name. No separate user name or connection name can be specified in that case.

There are also different ways to specify the user name:

- `username`
- `username/password`
- `username IDENTIFIED BY password`
- `username USING password`

As above, the parameters `username` and `password` can be an SQL identifier, an SQL string literal, or a reference to a character variable.

The `connection-name` is used to handle multiple connections in one program. It can be omitted if a program uses only one connection. The most recently opened connection becomes the current connection, which is used by default when an SQL statement is to be executed (see later in this chapter).

Here are some examples of `CONNECT` statements:

```
EXEC SQL CONNECT TO mydb@sql.mydomain.com;

EXEC SQL CONNECT TO unix:postgresql://sql.mydomain.com/mydb AS myconnection USER john;

EXEC SQL BEGIN DECLARE SECTION;
const char *target = "mydb@sql.mydomain.com";
const char *user = "john";
EXEC SQL END DECLARE SECTION;
...
EXEC SQL CONNECT TO :target USER :user;
```

The last form makes use of the variant referred to above as character variable reference. You will see in later sections how C variables can be used in SQL statements when you prefix them with a colon.

Be advised that the format of the connection target is not specified in the SQL standard. So if you want to develop portable applications, you might want to use something based on the last example above to encapsulate the connection target string somewhere.

## 32.3. Closing a Connection

To close a connection, use the following statement:

```
EXEC SQL DISCONNECT [connection];
```

The *connection* can be specified in the following ways:

- *connection-name*
- DEFAULT
- CURRENT
- ALL

If no connection name is specified, the current connection is closed.

It is good style that an application always explicitly disconnect from every connection it opened.

## 32.4. Running SQL Commands

Any SQL command can be run from within an embedded SQL application. Below are some examples of how to do that.

Creating a table:

```
EXEC SQL CREATE TABLE foo (number integer, ascii char(16));
EXEC SQL CREATE UNIQUE INDEX num1 ON foo(number);
EXEC SQL COMMIT;
```

Inserting rows:

```
EXEC SQL INSERT INTO foo (number, ascii) VALUES (9999, 'doodad');
EXEC SQL COMMIT;
```

Deleting rows:

```
EXEC SQL DELETE FROM foo WHERE number = 9999;
EXEC SQL COMMIT;
```

Single-row select:

```
EXEC SQL SELECT foo INTO :FooBar FROM table1 WHERE ascii = 'doodad';
```

Select using cursors:

```
EXEC SQL DECLARE foo_bar CURSOR FOR
    SELECT number, ascii FROM foo
    ORDER BY ascii;
EXEC SQL OPEN foo_bar;
EXEC SQL FETCH foo_bar INTO :FooBar, DooDad;
...
```

```
EXEC SQL CLOSE foo_bar;
EXEC SQL COMMIT;
```

Updates:

```
EXEC SQL UPDATE foo
    SET ascii = 'foobar'
    WHERE number = 9999;
EXEC SQL COMMIT;
```

The tokens of the form `:something` are *host variables*, that is, they refer to variables in the C program. They are explained in Section 32.6.

In the default mode, statements are committed only when `EXEC SQL COMMIT` is issued. The embedded SQL interface also supports autocommit of transactions (similar to `libpq` behavior) via the `-t` command-line option to `ecpg` (see below) or via the `EXEC SQL SET AUTOCOMMIT TO ON` statement. In autocommit mode, each command is automatically committed unless it is inside an explicit transaction block. This mode can be explicitly turned off using `EXEC SQL SET AUTOCOMMIT TO OFF`.

## 32.5. Choosing a Connection

The SQL statements shown in the previous section are executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, then there are two ways to handle this.

The first option is to explicitly choose a connection for each SQL statement, for example:

```
EXEC SQL AT connection-name SELECT ...;
```

This option is particularly suitable if the application needs to use several connections in mixed order.

If your application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread. If each thread uses its own connection, you will need to use the `AT` clause to specify which connection the thread will use.

The second option is to execute a statement to switch the current connection. That statement is:

```
EXEC SQL SET CONNECTION connection-name;
```

This option is particularly convenient if many statements are to be executed on the same connection. It is not thread-aware.

## 32.6. Using Host Variables

In Section 32.4 you saw how you can execute SQL statements from an embedded SQL program. Some of those statements only used fixed values and did not provide a way to insert user-supplied values into

statements or have the program process the values returned by the query. Those kinds of statements are not really useful in real applications. This section explains in detail how you can pass data between your C program and the embedded SQL statements using a simple mechanism called *host variables*. In an embedded SQL program we consider the SQL statements to be *guests* in the C program code which is the *host language*. Therefore the variables of the C program are called *host variables*.

### 32.6.1. Overview

Passing data between the C program and the SQL statements is particularly simple in embedded SQL. Instead of having the program paste the data into the statement, which entails various complications, such as properly quoting the value, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. For example:

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement refers to two C variables named `v1` and `v2` and also uses a regular SQL string literal, to illustrate that you are not restricted to use one kind of data or the other.

This style of inserting C variables in SQL statements works anywhere a value expression is expected in an SQL statement.

### 32.6.2. Declare Sections

To pass data from the program to the database, for example as parameters in a query, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION;
```

and ends with:

```
EXEC SQL END DECLARE SECTION;
```

Between those lines, there must be normal C variable declarations, such as:

```
int    x = 4;
char   foo[16], bar[16];
```

As you can see, you can optionally assign an initial value to the variable. The variable's scope is determined by the location of its declaring section within the program. You can also declare variables with the following syntax which implicitly creates a declare section:

```
EXEC SQL int i = 4;
```

You can have as many declare sections in a program as you like.

The declarations are also echoed to the output file as normal C variables, so there's no need to declare them again. Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.

The definition of a structure or union also must be listed inside a `DECLARE` section. Otherwise the preprocessor cannot handle these types since it does not know the definition.

### 32.6.3. Different types of host variables

As a host variable you can also use arrays, typedefs, structs and pointers. Moreover there are special types of host variables that exist only in ECPG.

A few examples on host variables:

#### Arrays

One of the most common uses of an array declaration is probably the allocation of a char array as in:

```
EXEC SQL BEGIN DECLARE SECTION;
    char str[50];
EXEC SQL END DECLARE SECTION;
```

Note that you have to take care of the length for yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

#### Typedefs

Use the `typedef` keyword to map new types to already existing types.

```
EXEC SQL BEGIN DECLARE SECTION;
    typedef char mychartype[40];
    typedef long serial_t;
EXEC SQL END DECLARE SECTION;
```

Note that you could also use:

```
EXEC SQL TYPE serial_t IS long;
```

This declaration does not need to be part of a declare section.

#### Pointers

You can declare pointers to the most common types. Note however that you cannot use pointers as target variables of queries without auto-allocation. See Section 32.10 for more information on auto-allocation.

```
EXEC SQL BEGIN DECLARE SECTION;
    int    *intp;
    char  **charp;
EXEC SQL END DECLARE SECTION;
```

#### Special types of variables

ECPG contains some special types that help you to interact easily with data from the SQL server. For example it has implemented support for the `varchar`, `numeric`, `date`, `timestamp`, and `interval` types. Section 32.8 contains basic functions to deal with those types, such that you do not need to send a query to the SQL server just for adding an interval to a timestamp for example.

The special type `VARCHAR` is converted into a named `struct` for every variable. A declaration like:

```
VARCHAR var[180];
```

is converted into:

```
struct varchar_var { int len; char arr[180]; } var;
```

This structure is suitable for interfacing with SQL datums of type `varchar`.

### 32.6.4. SELECT INTO and FETCH INTO

Now you should be able to pass data generated by your program into an SQL command. But how do you retrieve the results of a query? For that purpose, embedded SQL provides special variants of the usual commands `SELECT` and `FETCH`. These commands have a special `INTO` clause that specifies which host variables the retrieved values are to be stored in.

Here is an example:

```
/*
 * assume this table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */

EXEC SQL BEGIN DECLARE SECTION;
int v1;
VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;
```

So the `INTO` clause appears between the select list and the `FROM` clause. The number of elements in the select list and the list after `INTO` (also called the target list) must be equal.

Here is an example using the command `FETCH`:

```
EXEC SQL BEGIN DECLARE SECTION;
int v1;
VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;

...

do {
    ...
    EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
    ...
} while (...);
```

Here the `INTO` clause appears after all the normal clauses.

Both of these methods only allow retrieving one row at a time. If you need to process result sets that potentially contain more than one row, you need to use a cursor, as shown in the second example.

### 32.6.5. Indicators

The examples above do not handle null values. In fact, the retrieval examples will raise an error if they fetch a null value from the database. To be able to pass null values to the database or retrieve null values from the database, you need to append a second host variable specification to each host variable that contains data. This second host variable is called the *indicator* and contains a flag that tells whether the datum is null, in which case the value of the real host variable is ignored. Here is an example that handles the retrieval of null values correctly:

```
EXEC SQL BEGIN DECLARE SECTION;
VARCHAR val;
int val_ind;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL SELECT b INTO :val :val_ind FROM test1;
```

The indicator variable `val_ind` will be zero if the value was not null, and it will be negative if the value was null.

The indicator has another function: if the indicator value is positive, it means that the value is not null, but it was truncated when it was stored in the host variable.

## 32.7. Dynamic SQL

In many cases, the particular SQL statements that an application has to execute are known at the time the application is written. In some cases, however, the SQL statements are composed at run time or provided by an external source. In these cases you cannot embed the SQL statements directly into the C source code, but there is a facility that allows you to call arbitrary SQL statements that you provide in a string variable.

The simplest way to execute an arbitrary SQL statement is to use the command `EXECUTE IMMEDIATE`. For example:

```
EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "CREATE TABLE test1 (...);";
EXEC SQL END DECLARE SECTION;

EXEC SQL EXECUTE IMMEDIATE :stmt;
```

You cannot execute statements that retrieve data (e.g., `SELECT`) this way.

A more powerful way to execute arbitrary SQL statements is to prepare them once and execute the prepared statement as often as you like. It is also possible to prepare a generalized version of a statement and then execute specific versions of it by substituting parameters. When preparing the statement, write question marks where you want to substitute parameters later. For example:

```
EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "INSERT INTO test1 VALUES(?, ?);";
```

```
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt USING 42, 'foobar';
```

If the statement you are executing returns values, then add an INTO clause:

```
EXEC SQL BEGIN DECLARE SECTION;
const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";
int v1, v2;
VARCHAR v3;
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE mystmt FROM :stmt;
...
EXEC SQL EXECUTE mystmt INTO v1, v2, v3 USING 37;
```

An EXECUTE command can have an INTO clause, a USING clause, both, or neither.

When you don't need the prepared statement anymore, you should deallocate it:

```
EXEC SQL DEALLOCATE PREPARE name;
```

## 32.8. pgtypes library

The pgtypes library maps PostgreSQL database types to C equivalents that can be used in C programs. It also offers functions to do basic calculations with those types within C, i.e. without the help of the PostgreSQL server. See the following example:

```
EXEC SQL BEGIN DECLARE SECTION;
    date datel;
    timestamp tsl, tsout;
    interval ivl;
    char *out;
EXEC SQL END DECLARE SECTION;

PGTYPESdate_today(&datel);
EXEC SQL SELECT started, duration INTO :tsl, :ivl FROM datetbl WHERE d=:datel;
PGTYPEStimestamp_add_interval(&tsl, &ivl, &tsout);
out = PGTYPEStimestamp_to_asc(&tsout);
printf("Started + duration: %s\n", out);
free(out);
```

### 32.8.1. The numeric type

The numeric type offers to do calculations with arbitrary precision. See Section 8.1 for the equivalent type in the PostgreSQL server. Because of the arbitrary precision this variable needs to be able to expand and shrink dynamically. That's why you can only create variables on the heap by means of the `PGTYPESnumeric_new` and `PGTYPESnumeric_free` functions. The decimal type, which is similar but limited in the precision, can be created on the stack as well as on the heap.

The following functions can be used to work with the numeric type:

`PGTYPESnumeric_new`

Request a pointer to a newly allocated numeric variable.

```
numeric *PGTYPESnumeric_new(void);
```

`PGTYPESnumeric_free`

Free a numeric type, release all of its memory.

```
void PGTYPESnumeric_free(numeric *var);
```

`PGTYPESnumeric_from_asc`

Parse a numeric type from its string notation.

```
numeric *PGTYPESnumeric_from_asc(char *str, char **endptr);
```

Valid formats are for example: -2, .794, +3.44, 592.49E07 or -32.84e-4. If the value could be parsed successfully, a valid pointer is returned, else the NULL pointer. At the moment ecpg always parses the complete string and so it currently does not support to store the address of the first invalid character in `*endptr`. You can safely set `endptr` to NULL.

`PGTYPESnumeric_to_asc`

Returns a pointer to a string allocated by `malloc` that contains the string representation of the numeric type `num`.

```
char *PGTYPESnumeric_to_asc(numeric *num, int dscale);
```

The numeric value will be printed with `dscale` decimal digits, with rounding applied if necessary.

`PGTYPESnumeric_add`

Add two numeric variables into a third one.

```
int PGTYPESnumeric_add(numeric *var1, numeric *var2, numeric *result);
```

The function adds the variables `var1` and `var2` into the result variable `result`. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_sub`

Subtract two numeric variables and return the result in a third one.

```
int PGTYPESnumeric_sub(numeric *var1, numeric *var2, numeric *result);
```

The function subtracts the variable `var2` from the variable `var1`. The result of the operation is stored in the variable `result`. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_mul`

Multiply two numeric variables and return the result in a third one.

```
int PGTYPESnumeric_mul(numeric *var1, numeric *var2, numeric *result);
```

The function multiplies the variables `var1` and `var2`. The result of the operation is stored in the variable `result`. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_div`

Divide two numeric variables and return the result in a third one.

```
int PGTYPESnumeric_div(numeric *var1, numeric *var2, numeric *result);
```

The function divides the variables `var1` by `var2`. The result of the operation is stored in the variable `result`. The function returns 0 on success and -1 in case of error.

`PGTYPESnumeric_cmp`

Compare two numeric variables.

```
int PGTYPESnumeric_cmp(numeric *var1, numeric *var2)
```

This function compares two numeric variables. In case of error, `INT_MAX` is returned. On success, the function returns one of three possible results:

- 1, if `var1` is bigger than `var2`
- -1, if `var1` is smaller than `var2`
- 0, if `var1` and `var2` are equal

`PGTYPESnumeric_from_int`

Convert an int variable to a numeric variable.

```
int PGTYPESnumeric_from_int(signed int int_val, numeric *var);
```

This function accepts a variable of type `signed int` and stores it in the numeric variable `var`. Upon success, 0 is returned and -1 in case of a failure.

`PGTYPESnumeric_from_long`

Convert a long int variable to a numeric variable.

```
int PGTYPESnumeric_from_long(signed long int long_val, numeric *var);
```

This function accepts a variable of type `signed long int` and stores it in the numeric variable `var`. Upon success, 0 is returned and -1 in case of a failure.

`PGTYPESnumeric_copy`

Copy over one numeric variable into another one.

```
int PGTYPESnumeric_copy(numeric *src, numeric *dst);
```

This function copies over the value of the variable that `src` points to into the variable that `dst` points to. It returns 0 on success and -1 if an error occurs.

`PGTYPESnumeric_from_double`

Convert a variable of type double to a numeric.

```
int PGTYPESnumeric_from_double(double d, numeric *dst);
```

This function accepts a variable of type double and stores the result in the variable that `dst` points to. It returns 0 on success and -1 if an error occurs.

`PGTYPESnumeric_to_double`

Convert a variable of type numeric to double.

```
int PGTYPESnumeric_to_double(numeric *nv, double *dp)
```

The function converts the numeric value from the variable that `nv` points to into the double variable that `dp` points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable `errno` will be set to `PGTYPES_NUM_OVERFLOW` additionally.

`PGTYPESnumeric_to_int`

Convert a variable of type numeric to int.

```
int PGTYPESnumeric_to_int(numeric *nv, int *ip);
```

The function converts the numeric value from the variable that `nv` points to into the integer variable that `ip` points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable `errno` will be set to `PGTYPES_NUM_OVERFLOW` additionally.

`PGTYPESnumeric_to_long`

Convert a variable of type numeric to long.

```
int PGTYPESnumeric_to_long(numeric *nv, long *lp);
```

The function converts the numeric value from the variable that `nv` points to into the long integer variable that `lp` points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable `errno` will be set to `PGTYPES_NUM_OVERFLOW` additionally.

`PGTYPESnumeric_to_decimal`

Convert a variable of type numeric to decimal.

```
int PGTYPESnumeric_to_decimal(numeric *src, decimal *dst);
```

The function converts the numeric value from the variable that `src` points to into the decimal variable that `dst` points to. It returns 0 on success and -1 if an error occurs, including overflow. On overflow, the global variable `errno` will be set to `PGTYPES_NUM_OVERFLOW` additionally.

`PGTYPESnumeric_from_decimal`

Convert a variable of type decimal to numeric.

```
int PGTYPESnumeric_from_decimal(decimal *src, numeric *dst);
```

The function converts the decimal value from the variable that `src` points to into the numeric variable that `dst` points to. It returns 0 on success and -1 if an error occurs. Since the decimal type is implemented as a limited version of the numeric type, overflow cannot occur with this conversion.

## 32.8.2. The date type

The date type in C enables your programs to deal with data of the SQL type date. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the date type:

`PGTYPESdate_from_timestamp`

Extract the date part from a timestamp.

```
date PGTYPESdate_from_timestamp(timestamp dt);
```

The function receives a timestamp as its only argument and returns the extracted date part from this timestamp.

`PGTYPESdate_from_asc`

Parse a date from its textual representation.

```
date PGTYPESdate_from_asc(char *str, char **endptr);
```

The function receives a C char\* string `str` and a pointer to a C char\* string `endptr`. At the moment `ecpg` always parses the complete string and so it currently does not support to store the address of the first invalid character in `*endptr`. You can safely set `endptr` to `NULL`.

Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within `ecpg`.

The following input formats are allowed:

**Table 32-1. Valid input formats for `PGTYPESdate_from_asc`**

Input	Result
January 8, 1999	January 8, 1999
1999-01-08	January 8, 1999
1/8/1999	January 8, 1999
1/18/1999	January 18, 1999
01/02/03	February 1, 2003
1999-Jan-08	January 8, 1999
Jan-08-1999	January 8, 1999
08-Jan-1999	January 8, 1999
99-Jan-08	January 8, 1999
08-Jan-99	January 8, 1999
08-Jan-06	January 8, 2006
Jan-08-99	January 8, 1999
19990108	ISO 8601; January 8, 1999
990108	ISO 8601; January 8, 1999
1999.008	year and day of year
J2451187	Julian day
January 8, 99 BC	year 99 before the Common Era

`PGTYPESdate_to_asc`

Return the textual representation of a date variable.

```
char *PGTYPESdate_to_asc(date dDate);
```

The function receives the date `dDate` as its only parameter. It will output the date in the form `1999-01-18`, i.e. in the `YYYY-MM-DD` format.

`PGTYPESdate_julmdy`

Extract the values for the day, the month and the year from a variable of type date.

```
void PGTYPESdate_julmdy(date d, int *mdy);
```

The function receives the date `d` and a pointer to an array of 3 integer values `mdy`. The variable name indicates the sequential order: `mdy[0]` will be set to contain the number of the month, `mdy[1]` will be set to the value of the day and `mdy[2]` will contain the year.

`PGTYPESdate_mdyjul`

Create a date value from an array of 3 integers that specify the day, the month and the year of the date.

```
void PGTYPESdate_mdyjul(int *mdy, date *jdate);
```

The function receives the array of the 3 integers (`mdy`) as its first argument and as its second argument a pointer to a variable of type `date` that should hold the result of the operation.

`PGTYPESdate_dayofweek`

Return a number representing the day of the week for a date value.

```
int PGTYPESdate_dayofweek(date d);
```

The function receives the date variable `d` as its only argument and returns an integer that indicates the day of the week for this date.

- 0 - Sunday
- 1 - Monday
- 2 - Tuesday
- 3 - Wednesday
- 4 - Thursday
- 5 - Friday
- 6 - Saturday

`PGTYPESdate_today`

Get the current date.

```
void PGTYPESdate_today(date *d);
```

The function receives a pointer to a date variable (`d`) that it sets to the current date.

`PGTYPESdate_fmt_asc`

Convert a variable of type `date` to its textual representation using a format mask.

```
int PGTYPESdate_fmt_asc(date dDate, char *fmtstring, char *outbuf);
```

The function receives the date to convert (`dDate`), the format mask (`fmtstring`) and the string that will hold the textual representation of the date (`outbuf`).

On success, 0 is returned and a negative value if an error occurred.

The following literals are the field specifiers you can use:

- `dd` - The number of the day of the month.
- `mm` - The number of the month of the year.
- `yy` - The number of the year as a two digit number.
- `yyyy` - The number of the year as a four digit number.
- `ddd` - The name of the day (abbreviated).

- `mmm` - The name of the month (abbreviated).

All other characters are copied 1:1 to the output string.

The following table indicates a few possible formats. This will give you an idea of how to use this function. All output lines are based on the same date: November, 23rd, 1959.

**Table 32-2. Valid input formats for `PGTYPESdate_fmt_asc`**

<b>fmt</b>	<b>result</b>
<code>mmdyy</code>	112359
<code>ddmmyy</code>	231159
<code>yyymmdd</code>	591123
<code>yy/mm/dd</code>	59/11/23
<code>yy mm dd</code>	59 11 23
<code>yy.mm.dd</code>	59.11.23
<code>.mm.yyyy.dd.</code>	.11.1959.23.
<code>mmm. dd, yyyy</code>	Nov. 23, 1959
<code>mmm dd yyyy</code>	Nov 23 1959
<code>yyyy dd mm</code>	1959 23 11
<code>ddd, mmm. dd, yyyy</code>	Mon, Nov. 23, 1959
<code>(ddd) mmm. dd, yyyy</code>	(Mon) Nov. 23, 1959

#### `PGTYPESdate_defmt_asc`

Use a format mask to convert a C `char*` string to a value of type `date`.

```
int PGTYPESdate_defmt_asc(date *d, char *fmt, char *str);
```

The function receives a pointer to the date value that should hold the result of the operation (`d`), the format mask to use for parsing the date (`fmt`) and the C `char*` string containing the textual representation of the date (`str`). The textual representation is expected to match the format mask. However you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals `yy` or `yyyy` that indicate the position of the year, `mm` to indicate the position of the month and `dd` to indicate the position of the day.

The following table indicates a few possible formats. This will give you an idea of how to use this function.

**Table 32-3. Valid input formats for `rdefmtdate`**

<b>fmt</b>	<b>str</b>	<b>result</b>
<code>ddmmyy</code>	21-2-54	1954-02-21
<code>ddmmyy</code>	2-12-54	1954-12-02
<code>ddmmyy</code>	20111954	1954-11-20
<code>ddmmyy</code>	130464	1964-04-13
<code>mmm.dd.yyyy</code>	MAR-12-1967	1967-03-12

mmm.dd.yyyy	oct 28 1975	1975-10-28
mmddy	Nov 14th, 1985	1985-11-14

### 32.8.3. The timestamp type

The timestamp type in C enables your programs to deal with data of the SQL type timestamp. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the timestamp type:

`PGTYPEStimestamp_from_asc`

Parse a timestamp from its textual representation into a timestamp variable.

```
timestamp PGTYPEStimestamp_from_asc(char *str, char **endptr);
```

The function receives the string to parse (*str*) and a pointer to a C `char*` (*endptr*). At the moment `ecpg` always parses the complete string and so it currently does not support to store the address of the first invalid character in *endptr*. You can safely set *endptr* to `NULL`.

The function returns the parsed timestamp on success. On error, `PGTYPEStimestamp` is returned and `errno` is set to `PGTYPES_TS_BAD_TIMESTAMP`. See *PGTYPEStimestamp* for important notes on this value.

In general, the input string can contain any combination of an allowed date specification, a whitespace character and an allowed time specification. Note that timezones are not supported by `ecpg`. It can parse them but does not apply any calculation as the PostgreSQL server does for example. Timezone specifiers are silently discarded.

The following table contains a few examples for input strings:

**Table 32-4. Valid input formats for `PGTYPEStimestamp_from_asc`**

Input	Result
1999-01-08 04:05:06	1999-01-08 04:05:06
January 8 04:05:06 1999 PST	1999-01-08 04:05:06

Input	Result
1999-Jan-08 04:05:06.789-8	1999-01-08 04:05:06.789 (time zone specifier ignored)
J2451187 04:05-08:00	1999-01-08 04:05:00 (time zone specifier ignored)

`PGTYPEStimestamp_to_asc`

Converts a date to a C char\* string.

```
char *PGTYPEStimestamp_to_asc(timestamp tstamp);
```

The function receives the timestamp `tstamp` as its only argument and returns an allocated string that contains the textual representation of the timestamp.

`PGTYPEStimestamp_current`

Retrieve the current timestamp.

```
void PGTYPEStimestamp_current(timestamp *ts);
```

The function retrieves the current timestamp and saves it into the timestamp variable that `ts` points to.

`PGTYPEStimestamp_fmt_asc`

Convert a timestamp variable to a C char\* using a format mask.

```
int PGTYPEStimestamp_fmt_asc(timestamp *ts, char *output, int str_len, char *fmtstr);
```

The function receives a pointer to the timestamp to convert as its first argument (`ts`), a pointer to the output buffer (`output`), the maximal length that has been allocated for the output buffer (`str_len`) and the format mask to use for the conversion (`fmtstr`).

Upon success, the function returns 0 and a negative value if an error occurred.

You can use the following format specifiers for the format mask. The format specifiers are the same ones that are used in the `strftime` function in `libc`. Any non-format specifier will be copied into the output buffer.

- `%A` - is replaced by national representation of the full weekday name.
- `%a` - is replaced by national representation of the abbreviated weekday name.
- `%B` - is replaced by national representation of the full month name.
- `%b` - is replaced by national representation of the abbreviated month name.
- `%C` - is replaced by (year / 100) as decimal number; single digits are preceded by a zero.
- `%c` - is replaced by national representation of time and date.
- `%D` - is equivalent to `%m/%d/%y`.
- `%d` - is replaced by the day of the month as a decimal number (01-31).
- `%E*` `%O*` - POSIX locale extensions. The sequences `%Ec` `%EC` `%Ex` `%EX` `%Ey` `%EY` `%Od` `%Oe` `%OH` `%OI` `%Om` `%OM` `%OS` `%Ou` `%OU` `%OV` `%Ow` `%OW` `%Oy` are supposed to provide alternative representations.

Additionally `%OB` implemented to represent alternative months names (used standalone, without day mentioned).

- %e - is replaced by the day of month as a decimal number (1-31); single digits are preceded by a blank.
- %F - is equivalent to %Y-%m-%d.
- %G - is replaced by a year as a decimal number with century. This year is the one that contains the greater part of the week (Monday as the first day of the week).
- %g - is replaced by the same year as in %G, but as a decimal number without century (00-99).
- %H - is replaced by the hour (24-hour clock) as a decimal number (00-23).
- %h - the same as %b.
- %I - is replaced by the hour (12-hour clock) as a decimal number (01-12).
- %j - is replaced by the day of the year as a decimal number (001-366).
- %k - is replaced by the hour (24-hour clock) as a decimal number (0-23); single digits are preceded by a blank.
- %l - is replaced by the hour (12-hour clock) as a decimal number (1-12); single digits are preceded by a blank.
- %M - is replaced by the minute as a decimal number (00-59).
- %m - is replaced by the month as a decimal number (01-12).
- %n - is replaced by a newline.
- %O\* - the same as %E\*.
- %p - is replaced by national representation of either "ante meridiem" or "post meridiem" as appropriate.
- %R - is equivalent to %H:%M.
- %r - is equivalent to %I:%M:%S %p.
- %S - is replaced by the second as a decimal number (00-60).
- %s - is replaced by the number of seconds since the Epoch, UTC.
- %T - is equivalent to %H:%M:%S
- %t - is replaced by a tab.
- %U - is replaced by the week number of the year (Sunday as the first day of the week) as a decimal number (00-53).
- %u - is replaced by the weekday (Monday as the first day of the week) as a decimal number (1-7).
- %V - is replaced by the week number of the year (Monday as the first day of the week) as a decimal number (01-53). If the week containing January 1 has four or more days in the new year, then it is week 1; otherwise it is the last week of the previous year, and the next week is week 1.
- %v - is equivalent to %e-%b-%Y.
- %W - is replaced by the week number of the year (Monday as the first day of the week) as a decimal number (00-53).
- %w - is replaced by the weekday (Sunday as the first day of the week) as a decimal number (0-6).
- %X - is replaced by national representation of the time.

- `%x` - is replaced by national representation of the date.
- `%Y` - is replaced by the year with century as a decimal number.
- `%y` - is replaced by the year without century as a decimal number (00-99).
- `%Z` - is replaced by the time zone name.
- `%z` - is replaced by the time zone offset from UTC; a leading plus sign stands for east of UTC, a minus sign for west of UTC, hours and minutes follow with two digits each and no delimiter between them (common form for RFC 822 date headers).
- `%+` - is replaced by national representation of the date and time.
- `%-*` - GNU libc extension. Do not do any padding when performing numerical outputs.
- `$_*` - GNU libc extension. Explicitly specify space for padding.
- `%0*` - GNU libc extension. Explicitly specify zero for padding.
- `%%` - is replaced by `%`.

#### `PGTYPEStimestamp_sub`

Subtract one timestamp from another one and save the result in a variable of type interval.

```
int PGTYPEStimestamp_sub(timestamp *ts1, timestamp *ts2, interval *iv);
```

The function will subtract the timestamp variable that `ts2` points to from the timestamp variable that `ts1` points to and will store the result in the interval variable that `iv` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

#### `PGTYPEStimestamp_defmt_asc`

Parse a timestamp value from its textual representation using a formatting mask.

```
int PGTYPEStimestamp_defmt_asc(char *str, char *fmt, timestamp *d);
```

The function receives the textual representation of a timestamp in the variable `str` as well as the formatting mask to use in the variable `fmt`. The result will be stored in the variable that `d` points to.

If the formatting mask `fmt` is NULL, the function will fall back to the default formatting mask which is `%Y-%m-%d %H:%M:%S`.

This is the reverse function to `PGTYPEStimestamp_fmt_asc`. See the documentation there in order to find out about the possible formatting mask entries.

#### `PGTYPEStimestamp_add_interval`

Add an interval variable to a timestamp variable.

```
int PGTYPEStimestamp_add_interval(timestamp *tin, interval *span, timestamp *tout);
```

The function receives a pointer to a timestamp variable `tin` and a pointer to an interval variable `span`. It adds the interval to the timestamp and saves the resulting timestamp in the variable that `tout` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

#### `PGTYPEStimestamp_sub_interval`

Subtract an interval variable from a timestamp variable.

```
int PGTYPEStimestamp_sub_interval(timestamp *tin, interval *span, timestamp *tout);
```

The function subtracts the interval variable that `span` points to from the timestamp variable that `tin` points to and saves the result into the variable that `tout` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

### 32.8.4. The interval type

The interval type in C enables your programs to deal with data of the SQL type interval. See Section 8.5 for the equivalent type in the PostgreSQL server.

The following functions can be used to work with the interval type:

`PGTYPESEinterval_new`

Return a pointer to a newly allocated interval variable.

```
interval *PGTYPESEinterval_new(void);
```

`PGTYPESEinterval_free`

Release the memory of a previously allocated interval variable.

```
void PGTYPESEinterval_free(interval *intvl);
```

`PGTYPESEinterval_from_asc`

Parse an interval from its textual representation.

```
interval *PGTYPESEinterval_from_asc(char *str, char **endptr);
```

The function parses the input string `str` and returns a pointer to an allocated interval variable. At the moment `ecpg` always parses the complete string and so it currently does not support to store the address of the first invalid character in `*endptr`. You can safely set `endptr` to `NULL`.

`PGTYPESEinterval_to_asc`

Convert a variable of type interval to its textual representation.

```
char *PGTYPESEinterval_to_asc(interval *span);
```

The function converts the interval variable that `span` points to into a C `char*`. The output looks like this example: @ 1 day 12 hours 59 mins 10 secs.

`PGTYPESEinterval_copy`

Copy a variable of type interval.

```
int PGTYPESEinterval_copy(interval *intvlsrc, interval *intvldest);
```

The function copies the interval variable that `intvlsrc` points to into the variable that `intvldest` points to. Note that you need to allocate the memory for the destination variable before.

### 32.8.5. The decimal type

The decimal type is similar to the numeric type. However it is limited to a maximal precision of 30 significant digits. In contrast to the numeric type which can be created on the heap only, the decimal type can be created either on the stack or on the heap (by means of the functions `PGTYPESEdecimal_new()`

and `PGTYPESdecimal_free()`. There are a lot of other functions that deal with the decimal type in the Informix compatibility mode described in Section 32.9.

The following functions can be used to work with the decimal type and are not only contained in the `libcompat` library.

`PGTYPESdecimal_new`

Request a pointer to a newly allocated decimal variable.

```
decimal *PGTYPESdecimal_new(void);
```

`PGTYPESdecimal_free`

Free a decimal type, release all of its memory.

```
void PGTYPESdecimal_free(decimal *var);
```

## 32.8.6. errno values of pgtypeslib

`PGTYPES_NUM_BAD_NUMERIC`

An argument should contain a numeric variable (or point to a numeric variable) but in fact its in-memory representation was invalid.

`PGTYPES_NUM_OVERFLOW`

An overflow occurred. Since the numeric type can deal with almost arbitrary precision, converting a numeric variable into other types might cause overflow.

`PGTYPES_NUM_UNDERFLOW`

An underflow occurred. Since the numeric type can deal with almost arbitrary precision, converting a numeric variable into other types might cause underflow.

`PGTYPES_NUM_DIVIDE_ZERO`

A division by zero has been attempted.

`PGTYPES_DATE_BAD_DATE`

`PGTYPES_DATE_ERR_EARGS`

`PGTYPES_DATE_ERR_ENOSHORTDATE`

`PGTYPES_INTVL_BAD_INTERVAL`

`PGTYPES_DATE_ERR_ENOTDMY`

`PGTYPES_DATE_BAD_DAY`

`PGTYPES_DATE_BAD_MONTH`

PGTYPES\_TS\_BAD\_TIMESTAMP

### 32.8.7. Special constants of pgtypeslib

PGTYPESInvalidTimestamp

A value of type timestamp representing an invalid time stamp. This is returned by the function `PGTYPEStimestamp_from_asc` on parse error. Note that due to the internal representation of the timestamp datatype, `PGTYPESInvalidTimestamp` is also a valid timestamp at the same time. It is set to 1899-12-31 23:59:59. In order to detect errors, make sure that your application does not only test for `PGTYPESInvalidTimestamp` but also for `errno != 0` after each call to `PGTYPEStimestamp_from_asc`.

## 32.9. Informix compatibility mode

`ecpg` can be run in a so-called *Informix compatibility mode*. If this mode is active, it tries to behave as if it were the Informix precompiler for Informix E/SQL. Generally spoken this will allow you to use the dollar sign instead of the `EXEC SQL` primitive to introduce embedded SQL commands.:

```
$int j = 3;
$CONNECT TO :dbname;
$CREATE TABLE test(i INT PRIMARY KEY, j INT);
$INSERT INTO test(i, j) VALUES (7, :j);
$COMMIT;
```

There are two compatibility modes: `INFORMIX`, `INFORMIX_SE`

When linking programs that use this compatibility mode, remember to link against `libcompat` that is shipped with `ecpg`.

Besides the previously explained syntactic sugar, the Informix compatibility mode ports some functions for input, output and transformation of data as well as embedded SQL statements known from E/SQL to `ecpg`.

Informix compatibility mode is closely connected to the `pgtypeslib` library of `ecpg`. `pgtypeslib` maps SQL data types to data types within the C host program and most of the additional functions of the Informix compatibility mode allow you to operate on those C host program types. Note however that the extent of the compatibility is limited. It does not try to copy Informix behaviour; it allows you to do more or less the same operations and gives you functions that have the same name and the same basic behavior but it is no drop-in replacement if you are using Informix at the moment. Moreover, some of the data types are different. For example, PostgreSQL's datetime and interval types do not know about ranges like for example `YEAR TO MINUTE` so you won't find support in `ecpg` for that either.

### 32.9.1. Additional embedded SQL statements

`CLOSE DATABASE`

This statement closes the current connection. In fact, this is a synonym for `ecpg's DISCONNECT CURRENT.`

```
$CLOSE DATABASE;           /* close the current connection */
EXEC SQL CLOSE DATABASE;
```

### 32.9.2. Additional functions

`decadd`

Add two decimal type values.

```
int decadd(decimal *arg1, decimal *arg2, decimal *sum);
```

The function receives a pointer to the first operand of type decimal (`arg1`), a pointer to the second operand of type decimal (`arg2`) and a pointer to a value of type decimal that will contain the sum (`sum`). On success, the function returns 0. `ECPG_INFORMIX_NUM_OVERFLOW` is returned in case of overflow and `ECPG_INFORMIX_NUM_UNDERFLOW` in case of underflow. -1 is returned for other failures and `errno` is set to the respective `errno` number of the `pgtypeslib`.

`deccmp`

Compare two variables of type decimal.

```
int deccmp(decimal *arg1, decimal *arg2);
```

The function receives a pointer to the first decimal value (`arg1`), a pointer to the second decimal value (`arg2`) and returns an integer value that indicates which is the bigger value.

- 1, if the value that `arg1` points to is bigger than the value that `var2` points to
- -1, if the value that `arg1` points to is smaller than the value that `arg2` points to
- 0, if the value that `arg1` points to and the value that `arg2` points to are equal

`deccopy`

Copy a decimal value.

```
void deccopy(decimal *src, decimal *target);
```

The function receives a pointer to the decimal value that should be copied as the first argument (`src`) and a pointer to the target structure of type decimal (`target`) as the second argument.

`deccvasc`

Convert a value from its ASCII representation into a decimal type.

```
int deccvasc(char *cp, int len, decimal *np);
```

The function receives a pointer to string that contains the string representation of the number to be converted (`cp`) as well as its length `len`. `np` is a pointer to the decimal value that saves the result of the operation.

Valid formats are for example: -2, .794, +3.44, 592.49E07 or -32.84e-4.

The function returns 0 on success. If overflow or underflow occurred, ECPG\_INFORMIX\_NUM\_OVERFLOW or ECPG\_INFORMIX\_NUM\_UNDERFLOW is returned. If the ASCII representation could not be parsed, ECPG\_INFORMIX\_BAD\_NUMERIC is returned or ECPG\_INFORMIX\_BAD\_EXPONENT if this problem occurred while parsing the exponent.

deccvdbl

Convert a value of type double to a value of type decimal.

```
int deccvdbl(double dbl, decimal *np);
```

The function receives the variable of type double that should be converted as its first argument (dbl). As the second argument (np), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.

deccvint

Convert a value of type int to a value of type decimal.

```
int deccvint(int in, decimal *np);
```

The function receives the variable of type int that should be converted as its first argument (in). As the second argument (np), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.

deccvlong

Convert a value of type long to a value of type decimal.

```
int deccvlong(long lng, decimal *np);
```

The function receives the variable of type long that should be converted as its first argument (lng). As the second argument (np), the function receives a pointer to the decimal variable that should hold the result of the operation.

The function returns 0 on success and a negative value if the conversion failed.

decdiv

Divide two variables of type decimal.

```
int decdiv(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (n1) and the second (n2) operands and calculates n1/n2. result is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the division fails. If overflow or underflow occurred, the function returns ECPG\_INFORMIX\_NUM\_OVERFLOW or ECPG\_INFORMIX\_NUM\_UNDERFLOW respectively. If an attempt to divide by zero is observed, the function returns ECPG\_INFORMIX\_DIVIDE\_ZERO.

decmul

Multiply two decimal values.

```
int decmul(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (n1) and the second (n2) operands and calculates n1\*n2. result is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the multiplication fails. If overflow or underflow occurred, the function returns `ECPG_INFORMIX_NUM_OVERFLOW` or `ECPG_INFORMIX_NUM_UNDERFLOW` respectively.

#### decsub

Subtract one decimal value from another.

```
int decsub(decimal *n1, decimal *n2, decimal *result);
```

The function receives pointers to the variables that are the first (`n1`) and the second (`n2`) operands and calculates `n1-n2`. `result` is a pointer to the variable that should hold the result of the operation.

On success, 0 is returned and a negative value if the subtraction fails. If overflow or underflow occurred, the function returns `ECPG_INFORMIX_NUM_OVERFLOW` or `ECPG_INFORMIX_NUM_UNDERFLOW` respectively.

#### dectoasc

Convert a variable of type decimal to its ASCII representation in a C char\* string.

```
int dectoasc(decimal *np, char *cp, int len, int right)
```

The function receives a pointer to a variable of type decimal (`np`) that it converts to its textual representation. `cp` is the buffer that should hold the result of the operation. The parameter `right` specifies, how many digits right of the decimal point should be included in the output. The result will be rounded to this number of decimal digits. Setting `right` to -1 indicates that all available decimal digits should be included in the output. If the length of the output buffer, which is indicated by `len` is not sufficient to hold the textual representation including the trailing NUL character, only a single \* character is stored in the result and -1 is returned.

The function returns either -1 if the buffer `cp` was too small or `ECPG_INFORMIX_OUT_OF_MEMORY` if memory was exhausted.

#### dectodbl

Convert a variable of type decimal to a double.

```
int dectodbl(decimal *np, double *dblp);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the double variable that should hold the result of the operation (`dblp`).

On success, 0 is returned and a negative value if the conversion failed.

#### dectoint

Convert a variable to type decimal to an integer.

```
int dectoint(decimal *np, int *ip);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the integer variable that should hold the result of the operation (`ip`).

On success, 0 is returned and a negative value if the conversion failed. If an overflow occurred, `ECPG_INFORMIX_NUM_OVERFLOW` is returned.

Note that the `ecpg` implementation differs from the Informix implementation. Informix limits an integer to the range from -32767 to 32767, while the limits in the `ecpg` implementation depend on the architecture (`-INT_MAX .. INT_MAX`).

`dectolong`

Convert a variable to type decimal to a long integer.

```
int dectolong(decimal *np, long *lngp);
```

The function receives a pointer to the decimal value to convert (`np`) and a pointer to the long variable that should hold the result of the operation (`lngp`).

On success, 0 is returned and a negative value if the conversion failed. If an overflow occurred, `ECPG_INFORMIX_NUM_OVERFLOW` is returned.

Note that the `ecpg` implementation differs from the Informix implementation. Informix limits a long integer to the range from -2,147,483,647 to 2,147,483,647, while the limits in the `ecpg` implementation depend on the architecture (`-LONG_MAX` .. `LONG_MAX`).

`rdatestr`

Converts a date to a C char\* string.

```
int rdatestr(date d, char *str);
```

The function receives two arguments, the first one is the date to convert (`d`) and the second one is a pointer to the target string. The output format is always `yyyy-mm-dd`, so you need to allocate at least 11 bytes (including the NUL-terminator) for the string.

The function returns 0 on success and a negative value in case of error.

Note that `ecpg`'s implementation differs from the Informix implementation. In Informix the format can be influenced by setting environment variables. In `ecpg` however, you cannot change the output format.

`rstrdate`

Parse the textual representation of a date.

```
int rstrdate(char *str, date *d);
```

The function receives the textual representation of the date to convert (`str`) and a pointer to a variable of type `date` (`d`). This function does not allow you to specify a format mask. It uses the default format mask of Informix which is `mm/dd/yyyy`. Internally, this function is implemented by means of `rdefmtdate`. Therefore, `rstrdate` is not faster and if you have the choice you should opt for `rdefmtdate` which allows you to specify the format mask explicitly.

The function returns the same values as `rdefmtdate`.

`rtoday`

Get the current date.

```
void rtoday(date *d);
```

The function receives a pointer to a date variable (`d`) that it sets to the current date.

Internally this function uses the `PGTYPESdate_today` function.

`rjulmdy`

Extract the values for the day, the month and the year from a variable of type `date`.

```
int rjulmdy(date d, short mdy[3]);
```

The function receives the date `d` and a pointer to an array of 3 short integer values `mdy`. The variable name indicates the sequential order: `mdy[0]` will be set to contain the number of the month, `mdy[1]` will be set to the value of the day and `mdy[2]` will contain the year.

The function always returns 0 at the moment.

Internally the function uses the `PGTYPESdate_julmdy` function.

`rdefmtdate`

Use a format mask to convert a character string to a value of type date.

```
int rdefmtdate(date *d, char *fmt, char *str);
```

The function receives a pointer to the date value that should hold the result of the operation (`d`), the format mask to use for parsing the date (`fmt`) and the C `char*` string containing the textual representation of the date (`str`). The textual representation is expected to match the format mask. However you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals `yy` or `yyyy` that indicate the position of the year, `mm` to indicate the position of the month and `dd` to indicate the position of the day.

The function returns the following values:

- 0 - The function terminated successfully.
- `ECPG_INFORMIX_ENOSHORTDATE` - The date does not contain delimiters between day, month and year. In this case the input string must be exactly 6 or 8 bytes long but isn't.
- `ECPG_INFORMIX_ENOTDMY` - The format string did not correctly indicate the sequential order of year, month and day.
- `ECPG_INFORMIX_BAD_DAY` - The input string does not contain a valid day.
- `ECPG_INFORMIX_BAD_MONTH` - The input string does not contain a valid month.
- `ECPG_INFORMIX_BAD_YEAR` - The input string does not contain a valid year.

Internally this function is implemented to use the `PGTYPESdate_defmt_asc` function. See the reference there for a table of example input.

`rfmtdate`

Convert a variable of type date to its textual representation using a format mask.

```
int rfmtdate(date d, char *fmt, char *str);
```

The function receives the date to convert (`d`), the format mask (`fmt`) and the string that will hold the textual representation of the date (`str`).

On success, 0 is returned and a negative value if an error occurred.

Internally this function uses the `PGTYPESdate_fmt_asc` function, see the reference there for examples.

`rmidyjul`

Create a date value from an array of 3 short integers that specify the day, the month and the year of the date.

```
int rmidyjul(short mdy[3], date *d);
```

The function receives the array of the 3 short integers (`mdy`) and a pointer to a variable of type date that should hold the result of the operation.

Currently the function returns always 0.

Internally the function is implemented to use the function `PGTYPESdate_mdyjul`.

`rdayofweek`

Return a number representing the day of the week for a date value.

```
int rdayofweek(date d);
```

The function receives the date variable `d` as its only argument and returns an integer that indicates the day of the week for this date.

- 0 - Sunday
- 1 - Monday
- 2 - Tuesday
- 3 - Wednesday
- 4 - Thursday
- 5 - Friday
- 6 - Saturday

Internally the function is implemented to use the function `PGTYPESdate_dayofweek`.

`dtcurrent`

Retrieve the current timestamp.

```
void dtcurrent(timestamp *ts);
```

The function retrieves the current timestamp and saves it into the timestamp variable that `ts` points to.

`dtcvasc`

Parses a timestamp from its textual representation in ANSI standard into a timestamp variable.

```
int dtcvasc(char *str, timestamp *ts);
```

The function receives the string to parse (`str`) and a pointer to the timestamp variable that should hold the result of the operation (`ts`).

The function returns 0 on success and a negative value in case of error.

Internally this function uses the `PGTYPEStimestamp_from_asc` function. See the reference there for a table with example inputs.

`dtcvfmtasc`

Parses a timestamp from its textual representation in ANSI standard using a format mask into a timestamp variable.

```
dtcvfmtasc(char *inbuf, char *fmtstr, timestamp *dtvalue)
```

The function receives the string to parse (`inbuf`), the format mask to use (`fmtstr`) and a pointer to the timestamp variable that should hold the result of the operation (`ts`).

This functions is implemented by means of the `PGTYPEStimestamp_defmt_asc`. See the documentation there for a list of format specifiers that can be used.

The function returns 0 on success and a negative value in case of error.

`dtsub`

Subtract one timestamp from another and return a variable of type interval.

```
int dtsub(timestamp *ts1, timestamp *ts2, interval *iv);
```

The function will subtract the timestamp variable that `ts2` points to from the timestamp variable that `ts1` points to and will store the result in the interval variable that `iv` points to.

Upon success, the function returns 0 and a negative value if an error occurred.

`dttoasc`

Convert a timestamp variable to a C char\* string.

```
int dttoasc(timestamp *ts, char *output);
```

The function receives a pointer to the timestamp variable to convert (`ts`) and the string that should hold the result of the operation (`output`). It converts `ts` to its textual representation in the ANSI SQL standard which is defined to be `YYYY-MM-DD HH:MM:SS`.

Upon success, the function returns 0 and a negative value if an error occurred.

`dttofmtasc`

Convert a timestamp variable to a C char\* using a format mask.

```
int dttofmtasc(timestamp *ts, char *output, int str_len, char *fmtstr);
```

The function receives a pointer to the timestamp to convert as its first argument (`ts`), a pointer to the output buffer (`output`), the maximal length that has been allocated for the output buffer (`str_len`) and the format mask to use for the conversion (`fmtstr`).

Upon success, the function returns 0 and a negative value if an error occurred.

Internally, this function uses the `PGTYPEStimestamp_fmt_asc` function. See the reference there for information on what format mask specifiers can be used.

`intoasc`

Convert an interval variable to a C char\* string.

```
int intoasc(interval *i, char *str);
```

The function receives a pointer to the interval variable to convert (`i`) and the string that should hold the result of the operation (`str`). It converts `i` to its textual representation in the ANSI SQL standard which is defined to be `YYYY-MM-DD HH:MM:SS`.

Upon success, the function returns 0 and a negative value if an error occurred.

`rfmtlong`

Convert a long integer value to its textual representation using a format mask.

```
int rfmtlong(long lng_val, char *fmt, char *outbuf);
```

The function receives the long value `lng_val`, the format mask `fmt` and a pointer to the output buffer `outbuf`. It converts the long value according to the format mask to its textual representation.

The format mask can be composed of the following format specifying characters:

- \* (asterisk) - if this position would be blank otherwise, fill it with an asterisk.
- & (ampersand) - if this position would be blank otherwise, fill it with a zero.
- # - turn leading zeroes into blanks.
- < - left-justify the number in the string.

- , (comma) - group numbers of four or more digits into groups of three digits separated by a comma.
- . (period) - this character separates the whole-number part of the number from the fractional part.
- - (minus) - the minus sign appears if the number is a negative value.
- + (plus) - the plus sign appears if the number is a positive value.
- ( - this replaces the minus sign in front of the negative number. The minus sign will not appear.
- ) - this character replaces the minus and is printed behind the negative value.
- \$ - the currency symbol.

**rupshift**

Convert a string to upper case.

```
void rupshift(char *str);
```

The function receives a pointer to the string and transforms every lower case character to upper case.

**byleng**

Return the number of characters in a string without counting trailing blanks.

```
int byleng(char *str, int len);
```

The function expects a fixed-length string as its first argument (*str*) and its length as its second argument (*len*). It returns the number of significant characters, that is the length of the string without trailing blanks.

**ldchar**

Copy a fixed-length string into a null-terminated string.

```
void ldchar(char *src, int len, char *dest);
```

The function receives the fixed-length string to copy (*src*), its length (*len*) and a pointer to the destination memory (*dest*). Note that you need to reserve at least *len*+1 bytes for the string that *dest* points to. The function copies at most *len* bytes to the new location (less if the source string has trailing blanks) and adds the null-terminator.

**rgetmsg**

```
int rgetmsg(int msgnum, char *s, int maxsize);
```

This function exists but is not implemented at the moment!

**rtpalign**

```
int rtpalign(int offset, int type);
```

This function exists but is not implemented at the moment!

**rtpmsize**

```
int rtpmsize(int type, int len);
```

This function exists but is not implemented at the moment!

**rtpwidth**

```
int rtpwidth(int sqltype, int sqllen);
```

This function exists but is not implemented at the moment!

**rsetnull**

Set a variable to NULL.

```
int rsetnull(int t, char *ptr);
```

The function receives an integer that indicates the type of the variable and a pointer to the variable itself that is casted to a C char\* pointer.

The following types exist:

- CCHARTYPE - For a variable of type char or char\*
- CSHORTTYPE - For a variable of type short int
- CINTTYPE - For a variable of type int
- CBOOLTTYPE - For a variable of type boolean
- CFLOATTYPE - For a variable of type float
- CLONGTYPE - For a variable of type long
- CDOUBLETTYPE - For a variable of type double
- CDECIMALTYPE - For a variable of type decimal
- CDATETYPE - For a variable of type date
- CDTIMETYPE - For a variable of type timestamp

Here is an example of a call to this function:

```
$char c[] = "abc          ";
$short s = 17;
$int i = -74874;

rsetnull(CCHARTYPE, (char *) c);
rsetnull(CSHORTTYPE, (char *) &s);
rsetnull(CINTTYPE, (char *) &i);
```

**risnull**

Test if a variable is NULL.

```
int risnull(int t, char *ptr);
```

The function receives the type of the variable to test (t) as well a pointer to this variable (ptr). Note that the latter needs to be casted to a char\*. See the function *rsetnull* for a list of possible variable types.

Here is an example of how to use this function:

```
$char c[] = "abc          ";
$short s = 17;
$int i = -74874;

risnull(CCHARTYPE, (char *) c);
risnull(CSHORTTYPE, (char *) &s);
risnull(CINTTYPE, (char *) &i);
```

### 32.9.3. Additional constants

Note that all constants here describe errors and all of them are defined to represent negative values. In the descriptions of the different constants you can also find the value that the constants represent in the current implementation. However you should not rely on this number. You can however rely on the fact all of them are defined to represent negative values.

`ECPG_INFORMIX_NUM_OVERFLOW`

Functions return this value if an overflow occurred in a calculation. Internally it is defined to -1200 (the Informix definition).

`ECPG_INFORMIX_NUM_UNDERFLOW`

Functions return this value if an underflow occurred in a calculation. Internally it is defined to -1201 (the Informix definition).

`ECPG_INFORMIX_DIVIDE_ZERO`

Functions return this value if an attempt to divide by zero is observed. Internally it is defined to -1202 (the Informix definition).

`ECPG_INFORMIX_BAD_YEAR`

Functions return this value if a bad value for a year was found while parsing a date. Internally it is defined to -1204 (the Informix definition).

`ECPG_INFORMIX_BAD_MONTH`

Functions return this value if a bad value for a month was found while parsing a date. Internally it is defined to -1205 (the Informix definition).

`ECPG_INFORMIX_BAD_DAY`

Functions return this value if a bad value for a day was found while parsing a date. Internally it is defined to -1206 (the Informix definition).

`ECPG_INFORMIX_ENOSHORTDATE`

Functions return this value if a parsing routine needs a short date representation but did not get the date string in the right length. Internally it is defined to -1209 (the Informix definition).

`ECPG_INFORMIX_DATE_CONVERT`

Functions return this value if Internally it is defined to -1210 (the Informix definition).

`ECPG_INFORMIX_OUT_OF_MEMORY`

Functions return this value if Internally it is defined to -1211 (the Informix definition).

`ECPG_INFORMIX_ENOTDMY`

Functions return this value if a parsing routine was supposed to get a format mask (like `mmddyy`) but not all fields were listed correctly. Internally it is defined to -1212 (the Informix definition).

`ECPG_INFORMIX_BAD_NUMERIC`

Functions return this value either if a parsing routine cannot parse the textual representation for a numeric value because it contains errors or if a routine cannot complete a calculation involving numeric variables because at least one of the numeric variables is invalid. Internally it is defined to -1213 (the Informix definition).

ECPG\_INFORMIX\_BAD\_EXPONENT

Functions return this value if Internally it is defined to -1216 (the Informix definition).

ECPG\_INFORMIX\_BAD\_DATE

Functions return this value if Internally it is defined to -1218 (the Informix definition).

ECPG\_INFORMIX\_EXTRA\_CHARS

Functions return this value if Internally it is defined to -1264 (the Informix definition).

## 32.10. Using SQL Descriptor Areas

An SQL descriptor area is a more sophisticated method for processing the result of a `SELECT` or `FETCH` statement. An SQL descriptor area groups the data of one row of data together with metadata items into one data structure. The metadata is particularly useful when executing dynamic SQL statements, where the nature of the result columns might not be known ahead of time.

An SQL descriptor area consists of a header, which contains information concerning the entire descriptor, and one or more item descriptor areas, which basically each describe one column in the result row.

Before you can use an SQL descriptor area, you need to allocate one:

```
EXEC SQL ALLOCATE DESCRIPTOR identifier;
```

The identifier serves as the “variable name” of the descriptor area. When you don’t need the descriptor anymore, you should deallocate it:

```
EXEC SQL DEALLOCATE DESCRIPTOR identifier;
```

To use a descriptor area, specify it as the storage target in an `INTO` clause, instead of listing host variables:

```
EXEC SQL FETCH NEXT FROM mycursor INTO DESCRIPTOR mydesc;
```

Now how do you get the data out of the descriptor area? You can think of the descriptor area as a structure with named fields. To retrieve the value of a field from the header and store it into a host variable, use the following command:

```
EXEC SQL GET DESCRIPTOR name :hostvar = field;
```

Currently, there is only one header field defined: `COUNT`, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable needs to be of an integer type. To get a field from the item descriptor area, use the following command:

```
EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field;
```

*num* can be a literal integer or a host variable containing an integer. Possible fields are:

CARDINALITY (integer)

number of rows in the result set

DATA

actual data item (therefore, the data type of this field depends on the query)

DATETIME\_INTERVAL\_CODE (integer)

?

DATETIME\_INTERVAL\_PRECISION (integer)

not implemented

INDICATOR (integer)

the indicator (indicating a null value or a value truncation)

KEY\_MEMBER (integer)

not implemented

LENGTH (integer)

length of the datum in characters

NAME (string)

name of the column

NULLABLE (integer)

not implemented

OCTET\_LENGTH (integer)

length of the character representation of the datum in bytes

PRECISION (integer)

precision (for type `numeric`)

RETURNED\_LENGTH (integer)

length of the datum in characters

RETURNED\_OCTET\_LENGTH (integer)

length of the character representation of the datum in bytes

SCALE (integer)

scale (for type `numeric`)

TYPE (integer)

numeric code of the data type of the column

## 32.11. Error Handling

This section describes how you can handle exceptional conditions and warnings in an embedded SQL program. There are several nonexclusive facilities for this.

### 32.11.1. Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. In general:

```
EXEC SQL WHENEVER condition action;
```

*condition* can be one of the following:

SQLERROR

The specified action is called whenever an error occurs during the execution of an SQL statement.

SQLWARNING

The specified action is called whenever a warning occurs during the execution of an SQL statement.

NOT FOUND

The specified action is called whenever an SQL statement retrieves or affects zero rows. (This condition is not an error, but you might be interested in handling it specially.)

*action* can be one of the following:

CONTINUE

This effectively means that the condition is ignored. This is the default.

GOTO *label*

GO TO *label*

Jump to the specified label (using a C `goto` statement).

SQLPRINT

Print a message to standard error. This is useful for simple programs or during prototyping. The details of the message cannot be configured.

STOP

Call `exit(1)`, which will terminate the program.

DO BREAK

Execute the C statement `break`. This should only be used in loops or `switch` statements.

CALL *name* (*args*)

DO *name* (*args*)

Call the specified C functions with the specified arguments.

The SQL standard only provides for the actions `CONTINUE` and `GOTO` (and `GO TO`).

Here is an example that you might want to use in a simple program. It prints a simple message when a warning occurs and aborts the program when an error happens:

```
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLERROR STOP;
```

The statement `EXEC SQL WHENEVER` is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first `EXEC SQL WHENEVER` and the SQL statement causing the condition, regardless of the flow of control in the C program. So neither of the two following C program excerpts will have the desired effect:

```
/*
 * WRONG
 */
int main(int argc, char *argv[])
{
    ...
    if (verbose) {
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;
    }
    ...
    EXEC SQL SELECT ...;
    ...
}

/*
 * WRONG
 */
int main(int argc, char *argv[])
{
    ...
    set_error_handler();
    ...
    EXEC SQL SELECT ...;
    ...
}

static void set_error_handler(void)
{
    EXEC SQL WHENEVER SQLERROR STOP;
}
```

### 32.11.2. sqlca

For more powerful error handling, the embedded SQL interface provides a global variable with the name `sqlca` that has the following structure:

```
struct
{
    char sqlcaid[8];
    long sqlabc;
    long sqlcode;
    struct
    {
        int sqlerrml;
        char sqlerrmc[70];
    } sqlerrm;
    char sqlerrp[8];
    long sqlerrd[6];
    char sqlwarn[8];
    char sqlstate[5];
} sqlca;
```

(In a multithreaded program, every thread automatically gets its own copy of `sqlca`. This works similarly to the handling of the standard C global variable `errno`.)

`sqlca` covers both warnings and errors. If multiple warnings or errors occur during the execution of a statement, then `sqlca` will only contain information about the last one.

If no error occurred in the last SQL statement, `sqlca.sqlcode` will be 0 and `sqlca.sqlstate` will be "00000". If a warning or error occurred, then `sqlca.sqlcode` will be negative and `sqlca.sqlstate` will be different from "00000". A positive `sqlca.sqlcode` indicates a harmless condition, such as that the last query returned zero rows. `sqlcode` and `sqlstate` are two different error code schemes; details appear below.

If the last SQL statement was successful, then `sqlca.sqlerrd[1]` contains the OID of the processed row, if applicable, and `sqlca.sqlerrd[2]` contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, `sqlca.sqlerrm.sqlerrmc` will contain a string that describes the error. The field `sqlca.sqlerrm.sqlerrml` contains the length of the error message that is stored in `sqlca.sqlerrm.sqlerrmc` (the result of `strlen()`, not really interesting for a C programmer). Note that some messages are too long to fit in the fixed-size `sqlerrmc` array; they will be truncated.

In case of a warning, `sqlca.sqlwarn[2]` is set to W. (In all other cases, it is set to something different from W.) If `sqlca.sqlwarn[1]` is set to W, then a value was truncated when it was stored in a host variable. `sqlca.sqlwarn[0]` is set to W if any of the other elements are set to indicate a warning.

The fields `sqlcaid`, `sqlcabc`, `sqlerrp`, and the remaining elements of `sqlerrd` and `sqlwarn` currently contain no useful information.

The structure `sqlca` is not defined in the SQL standard, but is implemented in several other SQL database systems. The definitions are similar at the core, but if you want to write portable applications, then you should investigate the different implementations carefully.

### 32.11.3. SQLSTATE VS SQLCODE

The fields `sqlca.sqlstate` and `sqlca.sqlcode` are two different schemes that provide error codes. Both are derived from the SQL standard, but `SQLCODE` has been marked deprecated in the SQL-92 edition of the standard and has been dropped in later editions. Therefore, new applications are strongly encouraged to use `SQLSTATE`.

`SQLSTATE` is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. `SQLSTATE` has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. A successful state is indicated by the code `00000`. The `SQLSTATE` codes are for the most part defined in the SQL standard. The PostgreSQL server natively supports `SQLSTATE` error codes; therefore a high degree of consistency can be achieved by using this error code scheme throughout all applications. For further information see Appendix A.

`SQLCODE`, the deprecated error code scheme, is a simple integer. A value of 0 indicates success, a positive value indicates success with additional information, a negative value indicates an error. The SQL standard only defines the positive value `+100`, which indicates that the last command returned or affected zero rows, and no specific negative values. Therefore, this scheme can only achieve poor portability and does not have a hierarchical code assignment. Historically, the embedded SQL processor for PostgreSQL has assigned some specific `SQLCODE` values for its use, which are listed below with their numeric value and their symbolic name. Remember that these are not portable to other SQL implementations. To simplify the porting of applications to the `SQLSTATE` scheme, the corresponding `SQLSTATE` is also listed. There is, however, no one-to-one or one-to-many mapping between the two schemes (indeed it is many-to-many), so you should consult the global `SQLSTATE` listing in Appendix A in each case.

These are the assigned `SQLCODE` values:

-12 (`ECPG_OUT_OF_MEMORY`)

Indicates that your virtual memory is exhausted. (`SQLSTATE YE001`)

-200 (`ECPG_UNSUPPORTED`)

Indicates the preprocessor has generated something that the library does not know about. Perhaps you are running incompatible versions of the preprocessor and the library. (`SQLSTATE YE002`)

-201 (`ECPG_TOO_MANY_ARGUMENTS`)

This means that the command specified more host variables than the command expected. (`SQLSTATE 07001` or `07002`)

-202 (`ECPG_TOO_FEW_ARGUMENTS`)

This means that the command specified fewer host variables than the command expected. (`SQLSTATE 07001` or `07002`)

-203 (`ECPG_TOO_MANY_MATCHES`)

This means a query has returned multiple rows but the statement was only prepared to store one result row (for example, because the specified variables are not arrays). (`SQLSTATE 21000`)

-204 (`ECPG_INT_FORMAT`)

The host variable is of type `int` and the datum in the database is of a different type and contains a value that cannot be interpreted as an `int`. The library uses `strtol()` for this conversion. (`SQLSTATE 42804`)

-205 (ECPG\_UINT\_FORMAT)

The host variable is of type `unsigned int` and the datum in the database is of a different type and contains a value that cannot be interpreted as an `unsigned int`. The library uses `strtoul()` for this conversion. (SQLSTATE 42804)

-206 (ECPG\_FLOAT\_FORMAT)

The host variable is of type `float` and the datum in the database is of another type and contains a value that cannot be interpreted as a `float`. The library uses `strtod()` for this conversion. (SQLSTATE 42804)

-207 (ECPG\_CONVERT\_BOOL)

This means the host variable is of type `bool` and the datum in the database is neither `'t'` nor `'f'`. (SQLSTATE 42804)

-208 (ECPG\_EMPTY)

The statement sent to the PostgreSQL server was empty. (This cannot normally happen in an embedded SQL program, so it might point to an internal error.) (SQLSTATE YE002)

-209 (ECPG\_MISSING\_INDICATOR)

A null value was returned and no null indicator variable was supplied. (SQLSTATE 22002)

-210 (ECPG\_NO\_ARRAY)

An ordinary variable was used in a place that requires an array. (SQLSTATE 42804)

-211 (ECPG\_DATA\_NOT\_ARRAY)

The database returned an ordinary variable in a place that requires array value. (SQLSTATE 42804)

-220 (ECPG\_NO\_CONN)

The program tried to access a connection that does not exist. (SQLSTATE 08003)

-221 (ECPG\_NOT\_CONN)

The program tried to access a connection that does exist but is not open. (This is an internal error.) (SQLSTATE YE002)

-230 (ECPG\_INVALID\_STMT)

The statement you are trying to use has not been prepared. (SQLSTATE 26000)

-240 (ECPG\_UNKNOWN\_DESCRIPTOR)

The descriptor specified was not found. The statement you are trying to use has not been prepared. (SQLSTATE 33000)

-241 (ECPG\_INVALID\_DESCRIPTOR\_INDEX)

The descriptor index specified was out of range. (SQLSTATE 07009)

-242 (ECPG\_UNKNOWN\_DESCRIPTOR\_ITEM)

An invalid descriptor item was requested. (This is an internal error.) (SQLSTATE YE002)

-243 (ECPG\_VAR\_NOT\_NUMERIC)

During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric. (SQLSTATE 07006)

-244 (ECPG\_VAR\_NOT\_CHAR)

During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric. (SQLSTATE 07006)

-400 (ECPG\_PGSQL)

Some error caused by the PostgreSQL server. The message contains the error message from the PostgreSQL server.

-401 (ECPG\_TRANS)

The PostgreSQL server signaled that we cannot start, commit, or rollback the transaction. (SQLSTATE 08007)

-402 (ECPG\_CONNECT)

The connection attempt to the database did not succeed. (SQLSTATE 08001)

100 (ECPG\_NOT\_FOUND)

This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor. (SQLSTATE 02000)

## 32.12. Preprocessor directives

### 32.12.1. Including files

To include an external file into your embedded SQL program, use:

```
EXEC SQL INCLUDE filename;
```

The embedded SQL preprocessor will look for a file named `filename.h`, preprocess it, and include it in the resulting C output. Thus, embedded SQL statements in the included file are handled correctly.

Note that this is *not* the same as:

```
#include <filename.h>
```

because this file would not be subject to SQL command preprocessing. Naturally, you can continue to use the C `#include` directive to include other header files.

**Note:** The include file name is case-sensitive, even though the rest of the `EXEC SQL INCLUDE` command follows the normal SQL case-sensitivity rules.

### 32.12.2. The #define and #undef directives

Similar to the directive `#define` that is known from C, embedded SQL has a similar concept:

```
EXEC SQL DEFINE name;
EXEC SQL DEFINE name value;
```

So you can define a name:

```
EXEC SQL DEFINE HAVE_FEATURE;
```

And you can also define constants:

```
EXEC SQL DEFINE MYNUMBER 12;
EXEC SQL DEFINE MYSTRING 'abc';
```

Use `undef` to remove a previous definition:

```
EXEC SQL UNDEF MYNUMBER;
```

Of course you can continue to use the C versions `#define` and `#undef` in your embedded SQL program. The difference is where your defined values get evaluated. If you use `EXEC SQL DEFINE` then the `ecpg` preprocessor evaluates the defines and substitutes the values. For example if you write:

```
EXEC SQL DEFINE MYNUMBER 12;
...
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

then `ecpg` will already do the substitution and your C compiler will never see any name or identifier `MYNUMBER`. Note that you cannot use `#define` for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

### 32.12.3. ifdef, ifndef, else, elif and endif directives

You can use the following directives to compile code sections conditionally:

```
EXEC SQL ifdef name;
```

Checks a *name* and processes subsequent lines if *name* has been created with `EXEC SQL define name`.

```
EXEC SQL ifndef name;
```

Checks a *name* and processes subsequent lines if *name* has *not* been created with `EXEC SQL define name`.

```
EXEC SQL else;
```

Starts processing an alternative section to a section introduced by either `EXEC SQL ifdef name` or `EXEC SQL ifndef name`.

```
EXEC SQL elif name;
```

Checks *name* and starts an alternative section if *name* has been created with EXEC SQL define *name*.

```
EXEC SQL endif;
```

Ends an alternative section.

Example:

```
exec sql ifndef TZVAR;
exec sql SET TIMEZONE TO 'GMT';
exec sql elif TZNAME;
exec sql SET TIMEZONE TO TZNAME;
exec sql else;
exec sql SET TIMEZONE TO TZVAR;
exec sql endif;
```

## 32.13. Processing Embedded SQL Programs

Now that you have an idea how to form embedded SQL C programs, you probably want to know how to compile them. Before compiling you run the file through the embedded SQL C preprocessor, which converts the SQL statements you used to special function calls. After compiling, you must link with a special library that contains the needed functions. These functions fetch information from the arguments, perform the SQL command using the libpq interface, and put the result in the arguments specified for output.

The preprocessor program is called `ecpg` and is included in a normal PostgreSQL installation. Embedded SQL programs are typically named with an extension `.pgc`. If you have a program file called `prog1.pgc`, you can preprocess it by simply calling:

```
ecpg prog1.pgc
```

This will create a file called `prog1.c`. If your input files do not follow the suggested naming pattern, you can specify the output file explicitly using the `-o` option.

The preprocessed file can be compiled normally, for example:

```
cc -c prog1.c
```

The generated C source files include header files from the PostgreSQL installation, so if you installed PostgreSQL in a location that is not searched by default, you have to add an option such as `-I/usr/local/pgsql/include` to the compilation command line.

To link an embedded SQL program, you need to include the `libecpg` library, like so:

```
cc -o myprog prog1.o prog2.o ... -lecpq
```

Again, you might have to add an option like `-L/usr/local/pgsql/lib` to that command line.

If you manage the build process of a larger project using `make`, it might be convenient to include the following implicit rule to your makefiles:

```
ECPG = ecpgg

%.c: %.pgc
    $(ECPG) $<
```

The complete syntax of the `ecpg` command is detailed in `ecpg`.

The `ecpg` library is thread-safe if it is built using the `--enable-thread-safety` command-line option to `configure`. (You might need to use other threading command-line options to compile your client code.)

## 32.14. Library Functions

The `libecpg` library primarily contains “hidden” functions that are used to implement the functionality expressed by the embedded SQL commands. But there are some functions that can usefully be called directly. Note that this makes your code unportable.

- `ECPGdebug(int on, FILE *stream)` turns on debug logging if called with the first argument non-zero. Debug logging is done on `stream`. The log contains all SQL statements with all the input variables inserted, and the results from the PostgreSQL server. This can be very useful when searching for errors in your SQL statements.

**Note:** On Windows, if the `ecpg` libraries and an application are compiled with different flags, this function call will crash the application because the internal representation of the `FILE` pointers differ. Specifically, `multithreaded/single-threaded`, `release/debug`, and `static/dynamic` flags should be the same for the library and all applications using that library.

- `ECPGstatus(int lineno, const char* connection_name)` returns `true` if you are connected to a database and `false` if not. `connection_name` can be `NULL` if a single connection is being used.

## 32.15. Internals

This section explains how ECPG works internally. This information can occasionally be useful to help users understand how to use ECPG.

The first four lines written by `ecpg` to the output are fixed lines. Two are comments and two are include lines necessary to interface to the library. Then the preprocessor reads through the file and writes output. Normally it just echoes everything to the output.

When it sees an `EXEC SQL` statement, it intervenes and changes it. The command starts with `EXEC SQL` and ends with `;`. Everything in between is treated as an SQL statement and parsed for variable substitution.

Variable substitution occurs when a symbol starts with a colon (`:`). The variable with that name is looked up among the variables that were previously declared within a `EXEC SQL DECLARE` section.

The most important function in the library is `ECPGdo`, which takes care of executing most commands. It takes a variable number of arguments. This can easily add up to 50 or so arguments, and we hope this will not be a problem on any platform.

The arguments are:

A line number

This is the line number of the original line; used in error messages only.

A string

This is the SQL command that is to be issued. It is modified by the input variables, i.e., the variables that were not known at compile time but are to be entered in the command. Where the variables should go the string contains `?`.

Input variables

Every input variable causes ten arguments to be created. (See below.)

`ECPGt_EOIT`

An `enum` telling that there are no more input variables.

Output variables

Every output variable causes ten arguments to be created. (See below.) These variables are filled by the function.

`ECPGt_EORT`

An `enum` telling that there are no more variables.

For every variable that is part of the SQL command, the function gets ten arguments:

1. The type as a special symbol.
2. A pointer to the value or a pointer to the pointer.
3. The size of the variable if it is a `char` or `varchar`.
4. The number of elements in the array (for array fetches).
5. The offset to the next element in the array (for array fetches).
6. The type of the indicator variable as a special symbol.
7. A pointer to the indicator variable.
8. 0
9. The number of elements in the indicator array (for array fetches).
10. The offset to the next element in the indicator array (for array fetches).

Note that not all SQL commands are treated in this way. For instance, an open cursor statement like:

```
EXEC SQL OPEN cursor;
```

is not copied to the output. Instead, the cursor's `DECLARE` command is used at the position of the `OPEN` command because it indeed opens the cursor.

Here is a complete example describing the output of the preprocessor of a file `foo.pgc` (details might change with each particular version of the preprocessor):

```
EXEC SQL BEGIN DECLARE SECTION;
int index;
int result;
EXEC SQL END DECLARE SECTION;
...
EXEC SQL SELECT res INTO :result FROM mytable WHERE index = :index;
```

is translated into:

```
/* Processed by ecpg (2.6.0) */
/* These two include files are added by the preprocessor */
#include <ecpgtype.h>;
#include <ecpglib.h>;

/* exec sql begin declare section */

#line 1 "foo.pgc"

    int index;
    int result;
/* exec sql end declare section */
...
ECPGdo(__LINE__, NULL, "SELECT res FROM mytable WHERE index = ?      ",
        ECPGt_int,&(index),1L,1L,sizeof(int),
        ECPGt_NO_INDICATOR, NULL , 0L, 0L, 0L, ECPGt_EOIT,
        ECPGt_int,&(result),1L,1L,sizeof(int),
        ECPGt_NO_INDICATOR, NULL , 0L, 0L, 0L, ECPGt_EORT);
#line 147 "foo.pgc"
```

(The indentation here is added for readability and not something the preprocessor does.)

# Chapter 33. The Information Schema

The information schema consists of a set of views that contain information about the objects defined in the current database. The information schema is defined in the SQL standard and can therefore be expected to be portable and remain stable — unlike the system catalogs, which are specific to PostgreSQL and are modelled after implementation concerns. The information schema views do not, however, contain information about PostgreSQL-specific features; to inquire about those you need to query the system catalogs or other PostgreSQL-specific views.

## 33.1. The Schema

The information schema itself is a schema named `information_schema`. This schema automatically exists in all databases. The owner of this schema is the initial database user in the cluster, and that user naturally has all the privileges on this schema, including the ability to drop it (but the space savings achieved by that are minuscule).

By default, the information schema is not in the schema search path, so you need to access all objects in it through qualified names. Since the names of some of the objects in the information schema are generic names that might occur in user applications, you should be careful if you want to put the information schema in the path.

## 33.2. Data Types

The columns of the information schema views use special data types that are defined in the information schema. These are defined as simple domains over ordinary built-in types. You should not use these types for work outside the information schema, but your applications must be prepared for them if they select from the information schema.

These types are:

`cardinal_number`

A nonnegative integer.

`character_data`

A character string (without specific maximum length).

`sql_identifier`

A character string. This type is used for SQL identifiers, the type `character_data` is used for any other kind of text data.

`time_stamp`

A domain over the type `timestamp with time zone`

Every column in the information schema has one of these four types.

Boolean (true/false) data is represented in the information schema by a column of type `character_data` that contains either `YES` or `NO`. (The information schema was invented before the type `boolean` was

added to the SQL standard, so this convention is necessary to keep the information schema backward compatible.)

### 33.3. information\_schema\_catalog\_name

`information_schema_catalog_name` is a table that always contains one row and one column containing the name of the current database (current catalog, in SQL terminology).

**Table 33-1. information\_schema\_catalog\_name Columns**

Name	Data Type	Description
<code>catalog_name</code>	<code>sql_identifier</code>	Name of the database that contains this information schema

### 33.4. administrable\_role\_authorizations

The view `administrable_role_authorizations` identifies all roles that the current user has the admin option for.

**Table 33-2. administrable\_role\_authorizations Columns**

Name	Data Type	Description
<code>grantee</code>	<code>sql_identifier</code>	Name of the role to which this role membership was granted (can be the current user, or a different role in case of nested role memberships)
<code>role_name</code>	<code>sql_identifier</code>	Name of a role
<code>is_grantable</code>	<code>character_data</code>	Always YES

### 33.5. applicable\_roles

The view `applicable_roles` identifies all roles whose privileges the current user can use. This means there is some chain of role grants from the current user to the role in question. The current user itself is also an applicable role. The set of applicable roles is generally used for permission checking.

**Table 33-3. applicable\_roles Columns**

Name	Data Type	Description
------	-----------	-------------

Name	Data Type	Description
grantee	sql_identifier	Name of the role to which this role membership was granted (can be the current user, or a different role in case of nested role memberships)
role_name	sql_identifier	Name of a role
is_grantable	character_data	YES if the grantee has the admin option on the role, NO if not

## 33.6. attributes

The view `attributes` contains information about the attributes of composite data types defined in the database. (Note that the view does not give information about table columns, which are sometimes called attributes in PostgreSQL contexts.)

**Table 33-4. `attributes` Columns**

Name	Data Type	Description
udt_catalog	sql_identifier	Name of the database containing the data type (always the current database)
udt_schema	sql_identifier	Name of the schema containing the data type
udt_name	sql_identifier	Name of the data type
attribute_name	sql_identifier	Name of the attribute
ordinal_position	cardinal_number	Ordinal position of the attribute within the data type (count starts at 1)
attribute_default	character_data	Default expression of the attribute
is_nullable	character_data	YES if the attribute is possibly nullable, NO if it is known not nullable.
data_type	character_data	Data type of the attribute, if it is a built-in type, or ARRAY if it is some array (in that case, see the view <code>element_types</code> ), else USER-DEFINED (in that case, the type is identified in <code>attribute_udt_name</code> and associated columns).

Name	Data Type	Description
<code>character_maximum_length</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a character or bit string type, the declared maximum length; null for all other data types or if no maximum length was declared.
<code>character_octet_length</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a character type, the maximum possible length in octets (bytes) of a datum (this should not be of concern to PostgreSQL users); null for all other data types.
<code>numeric_precision</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a numeric type, this column contains the (declared or implicit) precision of the type for this attribute. The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.
<code>numeric_precision_radix</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a numeric type, this column indicates in which base the values in the columns <code>numeric_precision</code> and <code>numeric_scale</code> are expressed. The value is either 2 or 10. For all other data types, this column is null.

Name	Data Type	Description
<code>numeric_scale</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies an exact numeric type, this column contains the (declared or implicit) scale of the type for this attribute. The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.
<code>datetime_precision</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a date, time, or interval type, the declared precision; null for all other data types or if no precision was declared.
<code>interval_type</code>	<code>character_data</code>	Not yet implemented
<code>interval_precision</code>	<code>character_data</code>	Not yet implemented
<code>attribute_udt_catalog</code>	<code>sql_identifier</code>	Name of the database that the attribute data type is defined in (always the current database)
<code>attribute_udt_schema</code>	<code>sql_identifier</code>	Name of the schema that the attribute data type is defined in
<code>attribute_udt_name</code>	<code>sql_identifier</code>	Name of the attribute data type
<code>scope_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>maximum_cardinality</code>	<code>cardinal_number</code>	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL

Name	Data Type	Description
dtd_identifier	sql_identifier	An identifier of the data type descriptor of the column, unique among the data type descriptors pertaining to the table. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)
is_derived_reference_attribute_data	boolean	Applies to a feature not available in PostgreSQL

See also under Section 33.12, a similarly structured view, for further information on some of the columns.

## 33.7. check\_constraint\_routine\_usage

The view `check_constraint_routine_usage` identifies routines (functions and procedures) that are used by a check constraint. Only those routines are shown that are owned by a currently enabled role.

**Table 33-5. check\_constraint\_routine\_usage Columns**

Name	Data Type	Description
constraint_catalog	sql_identifier	Name of the database containing the constraint (always the current database)
constraint_schema	sql_identifier	Name of the schema containing the constraint
constraint_name	sql_identifier	Name of the constraint
specific_catalog	sql_identifier	Name of the database containing the function (always the current database)
specific_schema	sql_identifier	Name of the schema containing the function
specific_name	sql_identifier	The “specific name” of the function. See Section 33.29 for more information.

## 33.8. check\_constraints

The view `check_constraints` contains all check constraints, either defined on a table or on a domain, that are owned by a currently enabled role. (The owner of the table or domain is the owner of the con-

straint.)

**Table 33-6. `check_constraints` Columns**

Name	Data Type	Description
<code>constraint_catalog</code>	<code>sql_identifier</code>	Name of the database containing the constraint (always the current database)
<code>constraint_schema</code>	<code>sql_identifier</code>	Name of the schema containing the constraint
<code>constraint_name</code>	<code>sql_identifier</code>	Name of the constraint
<code>check_clause</code>	<code>character_data</code>	The check expression of the check constraint

## 33.9. `column_domain_usage`

The view `column_domain_usage` identifies all columns (of a table or a view) that make use of some domain defined in the current database and owned by a currently enabled role.

**Table 33-7. `column_domain_usage` Columns**

Name	Data Type	Description
<code>domain_catalog</code>	<code>sql_identifier</code>	Name of the database containing the domain (always the current database)
<code>domain_schema</code>	<code>sql_identifier</code>	Name of the schema containing the domain
<code>domain_name</code>	<code>sql_identifier</code>	Name of the domain
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database containing the table (always the current database)
<code>table_schema</code>	<code>sql_identifier</code>	Name of the schema containing the table
<code>table_name</code>	<code>sql_identifier</code>	Name of the table
<code>column_name</code>	<code>sql_identifier</code>	Name of the column

## 33.10. `column_privileges`

The view `column_privileges` identifies all privileges granted on columns to a currently enabled role or by a currently enabled role. There is one row for each combination of column, grantor, and grantee.

In PostgreSQL, you can only grant privileges on entire tables, not individual columns. Therefore, this

view contains the same information as `table_privileges`, just represented through one row for each column in each appropriate table, but it only covers privilege types where column granularity is possible: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`. If you want to make your applications fit for possible future developments, it is generally the right choice to use this view instead of `table_privileges` if one of those privilege types is concerned.

**Table 33-8. `column_privileges` Columns**

Name	Data Type	Description
<code>grantor</code>	<code>sql_identifier</code>	Name of the role that granted the privilege
<code>grantee</code>	<code>sql_identifier</code>	Name of the role that the privilege was granted to
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the table that contains the column (always the current database)
<code>table_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the table that contains the column
<code>table_name</code>	<code>sql_identifier</code>	Name of the table that contains the column
<code>column_name</code>	<code>sql_identifier</code>	Name of the column
<code>privilege_type</code>	<code>character_data</code>	Type of the privilege: <code>SELECT</code> , <code>INSERT</code> , <code>UPDATE</code> , or <code>REFERENCES</code>
<code>is_grantable</code>	<code>character_data</code>	YES if the privilege is grantable, NO if not

## 33.11. `column_udt_usage`

The view `column_udt_usage` identifies all columns that use data types owned by a currently enabled role. Note that in PostgreSQL, built-in data types behave like user-defined types, so they are included here as well. See also Section 33.12 for details.

**Table 33-9. `column_udt_usage` Columns**

Name	Data Type	Description
<code>udt_catalog</code>	<code>sql_identifier</code>	Name of the database that the column data type (the underlying type of the domain, if applicable) is defined in (always the current database)

Name	Data Type	Description
udt_schema	sql_identifier	Name of the schema that the column data type (the underlying type of the domain, if applicable) is defined in
udt_name	sql_identifier	Name of the column data type (the underlying type of the domain, if applicable)
table_catalog	sql_identifier	Name of the database containing the table (always the current database)
table_schema	sql_identifier	Name of the schema containing the table
table_name	sql_identifier	Name of the table
column_name	sql_identifier	Name of the column

## 33.12. columns

The view `columns` contains information about all table columns (or view columns) in the database. System columns (`oid`, etc.) are not included. Only those columns are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-10. `columns` Columns**

Name	Data Type	Description
table_catalog	sql_identifier	Name of the database containing the table (always the current database)
table_schema	sql_identifier	Name of the schema containing the table
table_name	sql_identifier	Name of the table
column_name	sql_identifier	Name of the column
ordinal_position	cardinal_number	Ordinal position of the column within the table (count starts at 1)
column_default	character_data	Default expression of the column
is_nullable	character_data	YES if the column is possibly nullable, NO if it is known not nullable. A not-null constraint is one way a column can be known not nullable, but there can be others.

Name	Data Type	Description
<code>data_type</code>	<code>character_data</code>	Data type of the column, if it is a built-in type, or <code>ARRAY</code> if it is some array (in that case, see the <code>view element_types</code> ), else <code>USER-DEFINED</code> (in that case, the type is identified in <code>udt_name</code> and associated columns). If the column is based on a domain, this column refers to the type underlying the domain (and the domain is identified in <code>domain_name</code> and associated columns).
<code>character_maximum_length</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a character or bit string type, the declared maximum length; null for all other data types or if no maximum length was declared.
<code>character_octet_length</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a character type, the maximum possible length in octets (bytes) of a datum (this should not be of concern to PostgreSQL users); null for all other data types.
<code>numeric_precision</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a numeric type, this column contains the (declared or implicit) precision of the type for this column. The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.

Name	Data Type	Description
<code>numeric_precision_radix</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a numeric type, this column indicates in which base the values in the columns <code>numeric_precision</code> and <code>numeric_scale</code> are expressed. The value is either 2 or 10. For all other data types, this column is null.
<code>numeric_scale</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies an exact numeric type, this column contains the (declared or implicit) scale of the type for this column. The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.
<code>datetime_precision</code>	<code>cardinal_number</code>	If <code>data_type</code> identifies a date, time, or interval type, the declared precision; null for all other data types or if no precision was declared.
<code>interval_type</code>	<code>character_data</code>	Not yet implemented
<code>interval_precision</code>	<code>character_data</code>	Not yet implemented
<code>character_set_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>character_set_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>character_set_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL

Name	Data Type	Description
domain_catalog	sql_identifier	If the column has a domain type, the name of the database that the domain is defined in (always the current database), else null.
domain_schema	sql_identifier	If the column has a domain type, the name of the schema that the domain is defined in, else null.
domain_name	sql_identifier	If the column has a domain type, the name of the domain, else null.
udt_catalog	sql_identifier	Name of the database that the column data type (the underlying type of the domain, if applicable) is defined in (always the current database)
udt_schema	sql_identifier	Name of the schema that the column data type (the underlying type of the domain, if applicable) is defined in
udt_name	sql_identifier	Name of the column data type (the underlying type of the domain, if applicable)
scope_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
scope_schema	sql_identifier	Applies to a feature not available in PostgreSQL
scope_name	sql_identifier	Applies to a feature not available in PostgreSQL
maximum_cardinality	cardinal_number	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL
dtd_identifier	sql_identifier	An identifier of the data type descriptor of the column, unique among the data type descriptors pertaining to the table. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)
is_self_referencing	character_data	Applies to a feature not available in PostgreSQL

Name	Data Type	Description
<code>is_identity</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_generation</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_start</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_increment</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_maximum</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_minimum</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>identity_cycle</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>is_generated</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>generation_expression</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>is_updatable</code>	<code>character_data</code>	YES if the column is updatable, NO if not (Columns in base tables are always updatable, columns in views not necessarily)

Since data types can be defined in a variety of ways in SQL, and PostgreSQL contains additional ways to define data types, their representation in the information schema can be somewhat difficult. The column `data_type` is supposed to identify the underlying built-in type of the column. In PostgreSQL, this means that the type is defined in the system catalog schema `pg_catalog`. This column might be useful if the application can handle the well-known built-in types specially (for example, format the numeric types differently or use the data in the precision columns). The columns `udt_name`, `udt_schema`, and `udt_catalog` always identify the underlying data type of the column, even if the column is based on a domain. (Since PostgreSQL treats built-in types like user-defined types, built-in types appear here as well. This is an extension of the SQL standard.) These columns should be used if an application wants to process data differently according to the type, because in that case it wouldn't matter if the column is really based on a domain. If the column is based on a domain, the identity of the domain is stored in the columns `domain_name`, `domain_schema`, and `domain_catalog`. If you want to pair up columns with their associated data types and treat domains as separate types, you could write `coalesce(domain_name, udt_name)`, etc.

### 33.13. `constraint_column_usage`

The view `constraint_column_usage` identifies all columns in the current database that are used by some constraint. Only those columns are shown that are contained in a table owned by a currently enabled role. For a check constraint, this view identifies the columns that are used in the check expression. For a

foreign key constraint, this view identifies the columns that the foreign key references. For a unique or primary key constraint, this view identifies the constrained columns.

**Table 33-11. `constraint_column_usage` Columns**

Name	Data Type	Description
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the table that contains the column that is used by some constraint (always the current database)
<code>table_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the table that contains the column that is used by some constraint
<code>table_name</code>	<code>sql_identifier</code>	Name of the table that contains the column that is used by some constraint
<code>column_name</code>	<code>sql_identifier</code>	Name of the column that is used by some constraint
<code>constraint_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the constraint (always the current database)
<code>constraint_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the constraint
<code>constraint_name</code>	<code>sql_identifier</code>	Name of the constraint

## 33.14. `constraint_table_usage`

The view `constraint_table_usage` identifies all tables in the current database that are used by some constraint and are owned by a currently enabled role. (This is different from the view `table_constraints`, which identifies all table constraints along with the table they are defined on.) For a foreign key constraint, this view identifies the table that the foreign key references. For a unique or primary key constraint, this view simply identifies the table the constraint belongs to. Check constraints and not-null constraints are not included in this view.

**Table 33-12. `constraint_table_usage` Columns**

Name	Data Type	Description
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the table that is used by some constraint (always the current database)

Name	Data Type	Description
table_schema	sql_identifier	Name of the schema that contains the table that is used by some constraint
table_name	sql_identifier	Name of the table that is used by some constraint
constraint_catalog	sql_identifier	Name of the database that contains the constraint (always the current database)
constraint_schema	sql_identifier	Name of the schema that contains the constraint
constraint_name	sql_identifier	Name of the constraint

## 33.15. data\_type\_privileges

The view `data_type_privileges` identifies all data type descriptors that the current user has access to, by way of being the owner of the described object or having some privilege for it. A data type descriptor is generated whenever a data type is used in the definition of a table column, a domain, or a function (as parameter or return type) and stores some information about how the data type is used in that instance (for example, the declared maximum length, if applicable). Each data type descriptor is assigned an arbitrary identifier that is unique among the data type descriptor identifiers assigned for one object (table, domain, function). This view is probably not useful for applications, but it is used to define some other views in the information schema.

**Table 33-13. data\_type\_privileges Columns**

Name	Data Type	Description
object_catalog	sql_identifier	Name of the database that contains the described object (always the current database)
object_schema	sql_identifier	Name of the schema that contains the described object
object_name	sql_identifier	Name of the described object
object_type	character_data	The type of the described object: one of <code>TABLE</code> (the data type descriptor pertains to a column of that table), <code>DOMAIN</code> (the data type descriptors pertains to that domain), <code>ROUTINE</code> (the data type descriptor pertains to a parameter or the return data type of that function).

Name	Data Type	Description
dtd_identifier	sql_identifier	The identifier of the data type descriptor, which is unique among the data type descriptors for that same object.

## 33.16. domain\_constraints

The view `domain_constraints` contains all constraints belonging to domains defined in the current database.

**Table 33-14. domain\_constraints Columns**

Name	Data Type	Description
constraint_catalog	sql_identifier	Name of the database that contains the constraint (always the current database)
constraint_schema	sql_identifier	Name of the schema that contains the constraint
constraint_name	sql_identifier	Name of the constraint
domain_catalog	sql_identifier	Name of the database that contains the domain (always the current database)
domain_schema	sql_identifier	Name of the schema that contains the domain
domain_name	sql_identifier	Name of the domain
is_deferrable	character_data	YES if the constraint is deferrable, NO if not
initially_deferred	character_data	YES if the constraint is deferrable and initially deferred, NO if not

## 33.17. domain\_udt\_usage

The view `domain_udt_usage` identifies all domains that are based on data types owned by a currently enabled role. Note that in PostgreSQL, built-in data types behave like user-defined types, so they are included here as well.

**Table 33-15. domain\_udt\_usage Columns**

Name	Data Type	Description
------	-----------	-------------

Name	Data Type	Description
udt_catalog	sql_identifier	Name of the database that the domain data type is defined in (always the current database)
udt_schema	sql_identifier	Name of the schema that the domain data type is defined in
udt_name	sql_identifier	Name of the domain data type
domain_catalog	sql_identifier	Name of the database that contains the domain (always the current database)
domain_schema	sql_identifier	Name of the schema that contains the domain
domain_name	sql_identifier	Name of the domain

## 33.18. domains

The view `domains` contains all domains defined in the current database.

**Table 33-16. domains Columns**

Name	Data Type	Description
domain_catalog	sql_identifier	Name of the database that contains the domain (always the current database)
domain_schema	sql_identifier	Name of the schema that contains the domain
domain_name	sql_identifier	Name of the domain
data_type	character_data	Data type of the domain, if it is a built-in type, or <code>ARRAY</code> if it is some array (in that case, see the view <code>element_types</code> ), else <code>USER-DEFINED</code> (in that case, the type is identified in <code>udt_name</code> and associated columns).
character_maximum_length	cardinal_number	If the domain has a character or bit string type, the declared maximum length; null for all other data types or if no maximum length was declared.

Name	Data Type	Description
<code>character_octet_length</code>	<code>cardinal_number</code>	If the domain has a character type, the maximum possible length in octets (bytes) of a datum (this should not be of concern to PostgreSQL users); null for all other data types.
<code>character_set_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>character_set_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>character_set_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>collation_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>numeric_precision</code>	<code>cardinal_number</code>	If the domain has a numeric type, this column contains the (declared or implicit) precision of the type for this column. The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.
<code>numeric_precision_radix</code>	<code>cardinal_number</code>	If the domain has a numeric type, this column indicates in which base the values in the columns <code>numeric_precision</code> and <code>numeric_scale</code> are expressed. The value is either 2 or 10. For all other data types, this column is null.

Name	Data Type	Description
<code>numeric_scale</code>	<code>cardinal_number</code>	If the domain has an exact numeric type, this column contains the (declared or implicit) scale of the type for this column. The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> . For all other data types, this column is null.
<code>datetime_precision</code>	<code>cardinal_number</code>	If the domain has a date, time, or interval type, the declared precision; null for all other data types or if no precision was declared.
<code>interval_type</code>	<code>character_data</code>	Not yet implemented
<code>interval_precision</code>	<code>character_data</code>	Not yet implemented
<code>domain_default</code>	<code>character_data</code>	Default expression of the domain
<code>udt_catalog</code>	<code>sql_identifier</code>	Name of the database that the domain data type is defined in (always the current database)
<code>udt_schema</code>	<code>sql_identifier</code>	Name of the schema that the domain data type is defined in
<code>udt_name</code>	<code>sql_identifier</code>	Name of the domain data type
<code>scope_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>maximum_cardinality</code>	<code>cardinal_number</code>	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL

Name	Data Type	Description
dtd_identifier	sql_identifier	An identifier of the data type descriptor of the domain, unique among the data type descriptors pertaining to the domain (which is trivial, because a domain only contains one data type descriptor). This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)

### 33.19. element\_types

The view `element_types` contains the data type descriptors of the elements of arrays. When a table column, domain, function parameter, or function return value is defined to be of an array type, the respective information schema view only contains `ARRAY` in the column `data_type`. To obtain information on the element type of the array, you can join the respective view with this view. For example, to show the columns of a table with data types and array element types, if applicable, you could do:

```
SELECT c.column_name, c.data_type, e.data_type AS element_type
FROM information_schema.columns c LEFT JOIN information_schema.element_types e
    ON ((c.table_catalog, c.table_schema, c.table_name, 'TABLE', c.dtd_identifier)
        = (e.object_catalog, e.object_schema, e.object_name, e.object_type, e.dtd_identifier)
WHERE c.table_schema = '...' AND c.table_name = '...'
ORDER BY c.ordinal_position;
```

This view only includes objects that the current user has access to, by way of being the owner or having some privilege.

**Table 33-17. element\_types Columns**

Name	Data Type	Description
object_catalog	sql_identifier	Name of the database that contains the object that uses the array being described (always the current database)
object_schema	sql_identifier	Name of the schema that contains the object that uses the array being described
object_name	sql_identifier	Name of the object that uses the array being described

Name	Data Type	Description
object_type	character_data	The type of the object that uses the array being described: one of <code>TABLE</code> (the array is used by a column of that table), <code>DOMAIN</code> (the array is used by that domain), <code>ROUTINE</code> (the array is used by a parameter or the return data type of that function).
dtd_identifier	sql_identifier	The identifier of the data type descriptor of the array being described
data_type	character_data	Data type of the array elements, if it is a built-in type, else <code>USER-DEFINED</code> (in that case, the type is identified in <code>udt_name</code> and associated columns).
character_maximum_length	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL
character_octet_length	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL
character_set_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_schema	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_name	sql_identifier	Applies to a feature not available in PostgreSQL
collation_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
collation_schema	sql_identifier	Applies to a feature not available in PostgreSQL
collation_name	sql_identifier	Applies to a feature not available in PostgreSQL
numeric_precision	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL
numeric_precision_radix	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL

Name	Data Type	Description
numeric_scale	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL
datetime_precision	cardinal_number	Always null, since this information is not applied to array element data types in PostgreSQL
interval_type	character_data	Always null, since this information is not applied to array element data types in PostgreSQL
interval_precision	character_data	Always null, since this information is not applied to array element data types in PostgreSQL
domain_default	character_data	Not yet implemented
udt_catalog	sql_identifier	Name of the database that the data type of the elements is defined in (always the current database)
udt_schema	sql_identifier	Name of the schema that the data type of the elements is defined in
udt_name	sql_identifier	Name of the data type of the elements
scope_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
scope_schema	sql_identifier	Applies to a feature not available in PostgreSQL
scope_name	sql_identifier	Applies to a feature not available in PostgreSQL
maximum_cardinality	cardinal_number	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL

## 33.20. enabled\_roles

The view `enabled_roles` identifies the currently “enabled roles”. The enabled roles are recursively defined as the current user together with all roles that have been granted to the enabled roles with automatic inheritance. In other words, these are all roles that the current user has direct or indirect, automatically inheriting membership in.

For permission checking, the set of “applicable roles” is applied, which can be broader than the set of enabled roles. So generally, it is better to use the view `applicable_roles` instead of this one; see also there.

**Table 33-18. `enabled_roles` Columns**

Name	Data Type	Description
<code>role_name</code>	<code>sql_identifier</code>	Name of a role

## 33.21. `key_column_usage`

The view `key_column_usage` identifies all columns in the current database that are restricted by some unique, primary key, or foreign key constraint. Check constraints are not included in this view. Only those columns are shown that the current user has access to, by way of being the owner or having some privilege.

**Table 33-19. `key_column_usage` Columns**

Name	Data Type	Description
<code>constraint_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the constraint (always the current database)
<code>constraint_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the constraint
<code>constraint_name</code>	<code>sql_identifier</code>	Name of the constraint
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the table that contains the column that is restricted by some constraint (always the current database)
<code>table_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the table that contains the column that is restricted by some constraint
<code>table_name</code>	<code>sql_identifier</code>	Name of the table that contains the column that is restricted by some constraint
<code>column_name</code>	<code>sql_identifier</code>	Name of the column that is restricted by some constraint
<code>ordinal_position</code>	<code>cardinal_number</code>	Ordinal position of the column within the constraint key (count starts at 1)
<code>position_in_unique_constraint</code>	<code>cardinal_number</code>	Not yet implemented

## 33.22. parameters

The view `parameters` contains information about the parameters (arguments) of all functions in the current database. Only those functions are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-20. `parameters` Columns**

Name	Data Type	Description
<code>specific_catalog</code>	<code>sql_identifier</code>	Name of the database containing the function (always the current database)
<code>specific_schema</code>	<code>sql_identifier</code>	Name of the schema containing the function
<code>specific_name</code>	<code>sql_identifier</code>	The “specific name” of the function. See Section 33.29 for more information.
<code>ordinal_position</code>	<code>cardinal_number</code>	Ordinal position of the parameter in the argument list of the function (count starts at 1)
<code>parameter_mode</code>	<code>character_data</code>	<code>IN</code> for input parameter, <code>OUT</code> for output parameter, and <code>INOUT</code> for input/output parameter.
<code>is_result</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>as_locator</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL
<code>parameter_name</code>	<code>sql_identifier</code>	Name of the parameter, or null if the parameter has no name
<code>data_type</code>	<code>character_data</code>	Data type of the parameter, if it is a built-in type, or <code>ARRAY</code> if it is some array (in that case, see the view <code>element_types</code> ), else <code>USER-DEFINED</code> (in that case, the type is identified in <code>udt_name</code> and associated columns).
<code>character_maximum_length</code>	<code>cardinal_number</code>	Always null, since this information is not applied to parameter data types in PostgreSQL
<code>character_octet_length</code>	<code>cardinal_number</code>	Always null, since this information is not applied to parameter data types in PostgreSQL

Name	Data Type	Description
character_set_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_schema	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_name	sql_identifier	Applies to a feature not available in PostgreSQL
collation_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
collation_schema	sql_identifier	Applies to a feature not available in PostgreSQL
collation_name	sql_identifier	Applies to a feature not available in PostgreSQL
numeric_precision	cardinal_number	Always null, since this information is not applied to parameter data types in PostgreSQL
numeric_precision_radix	cardinal_number	Always null, since this information is not applied to parameter data types in PostgreSQL
numeric_scale	cardinal_number	Always null, since this information is not applied to parameter data types in PostgreSQL
datetime_precision	cardinal_number	Always null, since this information is not applied to parameter data types in PostgreSQL
interval_type	character_data	Always null, since this information is not applied to parameter data types in PostgreSQL
interval_precision	character_data	Always null, since this information is not applied to parameter data types in PostgreSQL
udt_catalog	sql_identifier	Name of the database that the data type of the parameter is defined in (always the current database)
udt_schema	sql_identifier	Name of the schema that the data type of the parameter is defined in

Name	Data Type	Description
<code>udt_name</code>	<code>sql_identifier</code>	Name of the data type of the parameter
<code>scope_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>scope_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>maximum_cardinality</code>	<code>cardinal_number</code>	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL
<code>dtd_identifier</code>	<code>sql_identifier</code>	An identifier of the data type descriptor of the parameter, unique among the data type descriptors pertaining to the function. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)

### 33.23. `referential_constraints`

The view `referential_constraints` contains all referential (foreign key) constraints in the current database that belong to a table owned by a currently enabled role.

**Table 33-21. `referential_constraints` Columns**

Name	Data Type	Description
<code>constraint_catalog</code>	<code>sql_identifier</code>	Name of the database containing the constraint (always the current database)
<code>constraint_schema</code>	<code>sql_identifier</code>	Name of the schema containing the constraint
<code>constraint_name</code>	<code>sql_identifier</code>	Name of the constraint
<code>unique_constraint_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the unique or primary key constraint that the foreign key constraint references (always the current database)

Name	Data Type	Description
unique_constraint_schema	sql_identifier	Name of the schema that contains the unique or primary key constraint that the foreign key constraint references
unique_constraint_name	sql_identifier	Name of the unique or primary key constraint that the foreign key constraint references
match_option	character_data	Match option of the foreign key constraint: FULL, PARTIAL, or NONE.
update_rule	character_data	Update rule of the foreign key constraint: CASCADE, SET NULL, SET DEFAULT, RESTRICT, or NO ACTION.
delete_rule	character_data	Delete rule of the foreign key constraint: CASCADE, SET NULL, SET DEFAULT, RESTRICT, or NO ACTION.

## 33.24. role\_column\_grants

The view `role_column_grants` identifies all privileges granted on columns where the grantor or grantee is a currently enabled role. Further information can be found under `column_privileges`.

**Table 33-22. `role_column_grants` Columns**

Name	Data Type	Description
grantor	sql_identifier	Name of the role that granted the privilege
grantee	sql_identifier	Name of the role that the privilege was granted to
table_catalog	sql_identifier	Name of the database that contains the table that contains the column (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table that contains the column
table_name	sql_identifier	Name of the table that contains the column
column_name	sql_identifier	Name of the column

Name	Data Type	Description
privilege_type	character_data	Type of the privilege: SELECT, INSERT, UPDATE, or REFERENCES
is_grantable	character_data	YES if the privilege is grantable, NO if not

## 33.25. role\_routine\_grants

The view `role_routine_grants` identifies all privileges granted on functions where the grantor or grantee is a currently enabled role. Further information can be found under `routine_privileges`.

**Table 33-23. role\_routine\_grants Columns**

Name	Data Type	Description
grantor	sql_identifier	Name of the role that granted the privilege
grantee	sql_identifier	Name of the role that the privilege was granted to
specific_catalog	sql_identifier	Name of the database containing the function (always the current database)
specific_schema	sql_identifier	Name of the schema containing the function
specific_name	sql_identifier	The “specific name” of the function. See Section 33.29 for more information.
routine_catalog	sql_identifier	Name of the database containing the function (always the current database)
routine_schema	sql_identifier	Name of the schema containing the function
routine_name	sql_identifier	Name of the function (might be duplicated in case of overloading)
privilege_type	character_data	Always EXECUTE (the only privilege type for functions)
is_grantable	character_data	YES if the privilege is grantable, NO if not

## 33.26. role\_table\_grants

The view `role_table_grants` identifies all privileges granted on tables or views where the grantor or grantee is a currently enabled role. Further information can be found under `table_privileges`.

**Table 33-24. `role_table_grants` Columns**

Name	Data Type	Description
<code>grantor</code>	<code>sql_identifier</code>	Name of the role that granted the privilege
<code>grantee</code>	<code>sql_identifier</code>	Name of the role that the privilege was granted to
<code>table_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the table (always the current database)
<code>table_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the table
<code>table_name</code>	<code>sql_identifier</code>	Name of the table
<code>privilege_type</code>	<code>character_data</code>	Type of the privilege: SELECT, DELETE, INSERT, UPDATE, REFERENCES, or TRIGGER
<code>is_grantable</code>	<code>character_data</code>	YES if the privilege is grantable, NO if not
<code>with_hierarchy</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL

## 33.27. role\_usage\_grants

The view `role_usage_grants` is meant to identify `USAGE` privileges granted on various kinds of objects to a currently enabled role or by a currently enabled role. In PostgreSQL, this currently only applies to domains, and since domains do not have real privileges in PostgreSQL, this view is empty. Further information can be found under `usage_privileges`. In the future, this view might contain more useful information.

**Table 33-25. `role_usage_grants` Columns**

Name	Data Type	Description
<code>grantor</code>	<code>sql_identifier</code>	In the future, the name of the role that granted the privilege
<code>grantee</code>	<code>sql_identifier</code>	In the future, the name of the role that the privilege was granted to

Name	Data Type	Description
object_catalog	sql_identifier	Name of the database containing the object (always the current database)
object_schema	sql_identifier	Name of the schema containing the object
object_name	sql_identifier	Name of the object
object_type	character_data	In the future, the type of the object
privilege_type	character_data	Always USAGE
is_grantable	character_data	YES if the privilege is grantable, NO if not

## 33.28. routine\_privileges

The view `routine_privileges` identifies all privileges granted to a currently enabled role or by a currently enabled role. There is one row for each combination of function, grantor, and grantee.

**Table 33-26. routine\_privileges Columns**

Name	Data Type	Description
grantor	sql_identifier	Name of the role that granted the privilege
grantee	sql_identifier	Name of the role that the privilege was granted to
specific_catalog	sql_identifier	Name of the database containing the function (always the current database)
specific_schema	sql_identifier	Name of the schema containing the function
specific_name	sql_identifier	The “specific name” of the function. See Section 33.29 for more information.
routine_catalog	sql_identifier	Name of the database containing the function (always the current database)
routine_schema	sql_identifier	Name of the schema containing the function
routine_name	sql_identifier	Name of the function (might be duplicated in case of overloading)

Name	Data Type	Description
privilege_type	character_data	Always EXECUTE (the only privilege type for functions)
is_grantable	character_data	YES if the privilege is grantable, NO if not

## 33.29. routines

The view `routines` contains all functions in the current database. Only those functions are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-27. routines Columns**

Name	Data Type	Description
specific_catalog	sql_identifier	Name of the database containing the function (always the current database)
specific_schema	sql_identifier	Name of the schema containing the function
specific_name	sql_identifier	The “specific name” of the function. This is a name that uniquely identifies the function in the schema, even if the real name of the function is overloaded. The format of the specific name is not defined, it should only be used to compare it to other instances of specific routine names.
routine_catalog	sql_identifier	Name of the database containing the function (always the current database)
routine_schema	sql_identifier	Name of the schema containing the function
routine_name	sql_identifier	Name of the function (might be duplicated in case of overloading)
routine_type	character_data	Always FUNCTION (In the future there might be other types of routines.)
module_catalog	sql_identifier	Applies to a feature not available in PostgreSQL

Name	Data Type	Description
module_schema	sql_identifier	Applies to a feature not available in PostgreSQL
module_name	sql_identifier	Applies to a feature not available in PostgreSQL
udt_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
udt_schema	sql_identifier	Applies to a feature not available in PostgreSQL
udt_name	sql_identifier	Applies to a feature not available in PostgreSQL
data_type	character_data	Return data type of the function, if it is a built-in type, or ARRAY if it is some array (in that case, see the view <code>element_types</code> ), else USER-DEFINED (in that case, the type is identified in <code>type_udt_name</code> and associated columns).
character_maximum_length	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL
character_octet_length	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL
character_set_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_schema	sql_identifier	Applies to a feature not available in PostgreSQL
character_set_name	sql_identifier	Applies to a feature not available in PostgreSQL
collation_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
collation_schema	sql_identifier	Applies to a feature not available in PostgreSQL
collation_name	sql_identifier	Applies to a feature not available in PostgreSQL
numeric_precision	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL
numeric_precision_radix	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL

Name	Data Type	Description
numeric_scale	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL
datetime_precision	cardinal_number	Always null, since this information is not applied to return data types in PostgreSQL
interval_type	character_data	Always null, since this information is not applied to return data types in PostgreSQL
interval_precision	character_data	Always null, since this information is not applied to return data types in PostgreSQL
type_udt_catalog	sql_identifier	Name of the database that the return data type of the function is defined in (always the current database)
type_udt_schema	sql_identifier	Name of the schema that the return data type of the function is defined in
type_udt_name	sql_identifier	Name of the return data type of the function
scope_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
scope_schema	sql_identifier	Applies to a feature not available in PostgreSQL
scope_name	sql_identifier	Applies to a feature not available in PostgreSQL
maximum_cardinality	cardinal_number	Always null, because arrays always have unlimited maximum cardinality in PostgreSQL
dtd_identifier	sql_identifier	An identifier of the data type descriptor of the return data type of this function, unique among the data type descriptors pertaining to the function. This is mainly useful for joining with other instances of such identifiers. (The specific format of the identifier is not defined and not guaranteed to remain the same in future versions.)
routine_body	character_data	If the function is an SQL function, then SQL, else EXTERNAL.

Name	Data Type	Description
<code>routine_definition</code>	<code>character_data</code>	The source text of the function (null if the function is not owned by a currently enabled role). (According to the SQL standard, this column is only applicable if <code>routine_body</code> is SQL, but in PostgreSQL it will contain whatever source text was specified when the function was created.)
<code>external_name</code>	<code>character_data</code>	If this function is a C function, then the external name (link symbol) of the function; else null. (This works out to be the same value that is shown in <code>routine_definition</code> .)
<code>external_language</code>	<code>character_data</code>	The language the function is written in
<code>parameter_style</code>	<code>character_data</code>	Always <code>GENERAL</code> (The SQL standard defines other parameter styles, which are not available in PostgreSQL.)
<code>is_deterministic</code>	<code>character_data</code>	If the function is declared immutable (called deterministic in the SQL standard), then <code>YES</code> , else <code>NO</code> . (You cannot query the other volatility levels available in PostgreSQL through the information schema.)
<code>sql_data_access</code>	<code>character_data</code>	Always <code>MODIFIES</code> , meaning that the function possibly modifies SQL data. This information is not useful for PostgreSQL.
<code>is_null_call</code>	<code>character_data</code>	If the function automatically returns null if any of its arguments are null, then <code>YES</code> , else <code>NO</code> .
<code>sql_path</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL

Name	Data Type	Description
schema_level_routine	character_data	Always YES (The opposite would be a method of a user-defined type, which is a feature not available in PostgreSQL.)
max_dynamic_result_sets	cardinal_number	Applies to a feature not available in PostgreSQL
is_user_defined_cast	character_data	Applies to a feature not available in PostgreSQL
is_implicitly_invocable	character_data	Applies to a feature not available in PostgreSQL
security_type	character_data	If the function runs with the privileges of the current user, then INVOKER, if the function runs with the privileges of the user who defined it, then DEFINER.
to_sql_specific_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
to_sql_specific_schema	sql_identifier	Applies to a feature not available in PostgreSQL
to_sql_specific_name	sql_identifier	Applies to a feature not available in PostgreSQL
as_locator	character_data	Applies to a feature not available in PostgreSQL
created	time_stamp	Applies to a feature not available in PostgreSQL
last_altered	time_stamp	Applies to a feature not available in PostgreSQL
new_savepoint_level	character_data	Applies to a feature not available in PostgreSQL
is_udt_dependent	character_data	Applies to a feature not available in PostgreSQL
result_cast_from_data_type	character_data	Applies to a feature not available in PostgreSQL
result_cast_as_locator	character_data	Applies to a feature not available in PostgreSQL
result_cast_char_max_length	cardinal_number	Applies to a feature not available in PostgreSQL
result_cast_char_octet_length	character_data	Applies to a feature not available in PostgreSQL
result_cast_char_set_catalog	sql_identifier	Applies to a feature not available in PostgreSQL

Name	Data Type	Description
result_cast_char_set_schema	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_char_set_name	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_collation_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_collation_schema	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_collation_name	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_numeric_precision	cardinal_number	Applies to a feature not available in PostgreSQL
result_cast_numeric_precision_radix	cardinal_number	Applies to a feature not available in PostgreSQL
result_cast_numeric_scale	cardinal_number	Applies to a feature not available in PostgreSQL
result_cast_datetime_precision	character_data	Applies to a feature not available in PostgreSQL
result_cast_interval_type	character_data	Applies to a feature not available in PostgreSQL
result_cast_interval_precision	character_data	Applies to a feature not available in PostgreSQL
result_cast_type_udt_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_type_udt_schema	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_type_udt_name	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_scope_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_scope_schema	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_scope_name	sql_identifier	Applies to a feature not available in PostgreSQL
result_cast_maximum_cardinality	cardinal_number	Applies to a feature not available in PostgreSQL
result_cast_dtd_identifiers	sql_identifier	Applies to a feature not available in PostgreSQL

## 33.30. schemata

The view `schemata` contains all schemas in the current database that are owned by a currently enabled role.

**Table 33-28. `schemata` Columns**

Name	Data Type	Description
<code>catalog_name</code>	<code>sql_identifier</code>	Name of the database that the schema is contained in (always the current database)
<code>schema_name</code>	<code>sql_identifier</code>	Name of the schema
<code>schema_owner</code>	<code>sql_identifier</code>	Name of the owner of the schema
<code>default_character_set_catalog</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>default_character_set_schema</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>default_character_set_name</code>	<code>sql_identifier</code>	Applies to a feature not available in PostgreSQL
<code>sql_path</code>	<code>character_data</code>	Applies to a feature not available in PostgreSQL

## 33.31. sequences

The view `sequences` contains all sequences defined in the current database. Only those sequences are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-29. `sequences` Columns**

Name	Data Type	Description
<code>sequence_catalog</code>	<code>sql_identifier</code>	Name of the database that contains the sequence (always the current database)
<code>sequence_schema</code>	<code>sql_identifier</code>	Name of the schema that contains the sequence
<code>sequence_name</code>	<code>sql_identifier</code>	Name of the sequence
<code>data_type</code>	<code>character_data</code>	The data type of the sequence. In PostgreSQL, this is currently always <code>bigint</code> .

Name	Data Type	Description
<code>numeric_precision</code>	<code>cardinal_number</code>	This column contains the (declared or implicit) precision of the sequence data type (see above). The precision indicates the number of significant digits. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> .
<code>numeric_precision_radix</code>	<code>cardinal_number</code>	This column indicates in which base the values in the columns <code>numeric_precision</code> and <code>numeric_scale</code> are expressed. The value is either 2 or 10.
<code>numeric_scale</code>	<code>cardinal_number</code>	This column contains the (declared or implicit) scale of the sequence data type (see above). The scale indicates the number of significant digits to the right of the decimal point. It can be expressed in decimal (base 10) or binary (base 2) terms, as specified in the column <code>numeric_precision_radix</code> .
<code>maximum_value</code>	<code>cardinal_number</code>	Not yet implemented
<code>minimum_value</code>	<code>cardinal_number</code>	Not yet implemented
<code>increment</code>	<code>cardinal_number</code>	Not yet implemented
<code>cycle_option</code>	<code>character_data</code>	Not yet implemented

## 33.32. `sql_features`

The table `sql_features` contains information about which formal features defined in the SQL standard are supported by PostgreSQL. This is the same information that is presented in Appendix D. There you can also find some additional background information.

**Table 33-30. `sql_features` Columns**

Name	Data Type	Description
<code>feature_id</code>	<code>character_data</code>	Identifier string of the feature
<code>feature_name</code>	<code>character_data</code>	Descriptive name of the feature

Name	Data Type	Description
sub_feature_id	character_data	Identifier string of the subfeature, or a zero-length string if not a subfeature
sub_feature_name	character_data	Descriptive name of the subfeature, or a zero-length string if not a subfeature
is_supported	character_data	YES if the feature is fully supported by the current version of PostgreSQL, NO if not
is_verified_by	character_data	Always null, since the PostgreSQL development group does not perform formal testing of feature conformance
comments	character_data	Possibly a comment about the supported status of the feature

### 33.33. sql\_implementation\_info

The table `sql_implementation_info` contains information about various aspects that are left implementation-defined by the SQL standard. This information is primarily intended for use in the context of the ODBC interface; users of other interfaces will probably find this information to be of little use. For this reason, the individual implementation information items are not described here; you will find them in the description of the ODBC interface.

**Table 33-31. sql\_implementation\_info Columns**

Name	Data Type	Description
implementation_info_id	character_data	Identifier string of the implementation information item
implementation_info_name	character_data	Descriptive name of the implementation information item
integer_value	cardinal_number	Value of the implementation information item, or null if the value is contained in the column <code>character_value</code>
character_value	character_data	Value of the implementation information item, or null if the value is contained in the column <code>integer_value</code>

Name	Data Type	Description
comments	character_data	Possibly a comment pertaining to the implementation information item

### 33.34. sql\_languages

The table `sql_languages` contains one row for each SQL language binding that is supported by PostgreSQL. PostgreSQL supports direct SQL and embedded SQL in C; that is all you will learn from this table.

**Table 33-32. `sql_languages` Columns**

Name	Data Type	Description
<code>sql_language_source</code>	character_data	The name of the source of the language definition; always ISO 9075, that is, the SQL standard
<code>sql_language_year</code>	character_data	The year the standard referenced in <code>sql_language_source</code> was approved; currently 2003
<code>sql_language_conformance</code>	character_data	The standard conformance level for the language binding. For ISO 9075:2003 this is always CORE.
<code>sql_language_integrity</code>	character_data	Always null (This value is relevant to an earlier version of the SQL standard.)
<code>sql_language_implementation</code>	character_data	Always null
<code>sql_language_binding_style</code>	character_data	The language binding style, either <code>DIRECT</code> or <code>EMBEDDED</code>
<code>sql_language_programming_language</code>	character_data	The programming language, if the binding style is <code>EMBEDDED</code> , else null. PostgreSQL only supports the language C.

### 33.35. sql\_packages

The table `sql_packages` contains information about which feature packages defined in the SQL standard are supported by PostgreSQL. Refer to Appendix D for background information on feature packages.

**Table 33-33. sql\_packages Columns**

Name	Data Type	Description
feature_id	character_data	Identifier string of the package
feature_name	character_data	Descriptive name of the package
is_supported	character_data	YES if the package is fully supported by the current version of PostgreSQL, NO if not
is_verified_by	character_data	Always null, since the PostgreSQL development group does not perform formal testing of feature conformance
comments	character_data	Possibly a comment about the supported status of the package

### 33.36. sql\_parts

The table `sql_parts` contains information about which of the several parts of the SQL standard are supported by PostgreSQL.

**Table 33-34. sql\_parts Columns**

Name	Data Type	Description
feature_id	character_data	An identifier string containing the number of the part
feature_name	character_data	Descriptive name of the part
is_supported	character_data	YES if the part is fully supported by the current version of PostgreSQL, NO if not
is_verified_by	character_data	Always null, since the PostgreSQL development group does not perform formal testing of feature conformance
comments	character_data	Possibly a comment about the supported status of the part

### 33.37. sql\_sizing

The table `sql_sizing` contains information about various size limits and maximum values in PostgreSQL. This information is primarily intended for use in the context of the ODBC interface; users of other interfaces will probably find this information to be of little use. For this reason, the individual sizing items are not described here; you will find them in the description of the ODBC interface.

**Table 33-35. `sql_sizing` Columns**

Name	Data Type	Description
sizing_id	cardinal_number	Identifier of the sizing item
sizing_name	character_data	Descriptive name of the sizing item
supported_value	cardinal_number	Value of the sizing item, or 0 if the size is unlimited or cannot be determined, or null if the features for which the sizing item is applicable are not supported
comments	character_data	Possibly a comment pertaining to the sizing item

### 33.38. `sql_sizing_profiles`

The table `sql_sizing_profiles` contains information about the `sql_sizing` values that are required by various profiles of the SQL standard. PostgreSQL does not track any SQL profiles, so this table is empty.

**Table 33-36. `sql_sizing_profiles` Columns**

Name	Data Type	Description
sizing_id	cardinal_number	Identifier of the sizing item
sizing_name	character_data	Descriptive name of the sizing item
profile_id	character_data	Identifier string of a profile
required_value	cardinal_number	The value required by the SQL profile for the sizing item, or 0 if the profile places no limit on the sizing item, or null if the profile does not require any of the features for which the sizing item is applicable
comments	character_data	Possibly a comment pertaining to the sizing item within the profile

### 33.39. `table_constraints`

The view `table_constraints` contains all constraints belonging to tables that the current user owns or has some privilege on.

**Table 33-37. table\_constraints Columns**

Name	Data Type	Description
constraint_catalog	sql_identifier	Name of the database that contains the constraint (always the current database)
constraint_schema	sql_identifier	Name of the schema that contains the constraint
constraint_name	sql_identifier	Name of the constraint
table_catalog	sql_identifier	Name of the database that contains the table (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table
table_name	sql_identifier	Name of the table
constraint_type	character_data	Type of the constraint: CHECK, FOREIGN KEY, PRIMARY KEY, or UNIQUE
is_deferrable	character_data	YES if the constraint is deferrable, NO if not
initially_deferred	character_data	YES if the constraint is deferrable and initially deferred, NO if not

## 33.40. table\_privileges

The view `table_privileges` identifies all privileges granted on tables or views to a currently enabled role or by a currently enabled role. There is one row for each combination of table, grantor, and grantee.

**Table 33-38. table\_privileges Columns**

Name	Data Type	Description
grantor	sql_identifier	Name of the role that granted the privilege
grantee	sql_identifier	Name of the role that the privilege was granted to
table_catalog	sql_identifier	Name of the database that contains the table (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table
table_name	sql_identifier	Name of the table

Name	Data Type	Description
privilege_type	character_data	Type of the privilege: SELECT, DELETE, INSERT, UPDATE, REFERENCES, or TRIGGER
is_grantable	character_data	YES if the privilege is grantable, NO if not
with_hierarchy	character_data	Applies to a feature not available in PostgreSQL

## 33.41. tables

The view `tables` contains all tables and views defined in the current database. Only those tables and views are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-39. `tables` Columns**

Name	Data Type	Description
table_catalog	sql_identifier	Name of the database that contains the table (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table
table_name	sql_identifier	Name of the table
table_type	character_data	Type of the table: <code>BASE TABLE</code> for a persistent base table (the normal table type), <code>VIEW</code> for a view, or <code>LOCAL TEMPORARY</code> for a temporary table
self_referencing_column_name	sql_identifier	Applies to a feature not available in PostgreSQL
reference_generation	character_data	Applies to a feature not available in PostgreSQL
user_defined_type_catalog	sql_identifier	Applies to a feature not available in PostgreSQL
user_defined_type_schema	sql_identifier	Applies to a feature not available in PostgreSQL
user_defined_type_name	sql_identifier	Applies to a feature not available in PostgreSQL
is_insertable_into	character_data	YES if the table is insertable into, NO if not (Base tables are always insertable into, views not necessarily.)

Name	Data Type	Description
is_typed	character_data	Applies to a feature not available in PostgreSQL
commit_action	character_data	If the table is a temporary table, then <code>PRESERVE</code> , else null. (The SQL standard defines other commit actions for temporary tables, which are not supported by PostgreSQL.)

## 33.42. triggers

The view `triggers` contains all triggers defined in the current database on tables that the current user owns or has some privilege on.

**Table 33-40. triggers Columns**

Name	Data Type	Description
trigger_catalog	sql_identifier	Name of the database that contains the trigger (always the current database)
trigger_schema	sql_identifier	Name of the schema that contains the trigger
trigger_name	sql_identifier	Name of the trigger
event_manipulation	character_data	Event that fires the trigger (INSERT, UPDATE, or DELETE)
event_object_catalog	sql_identifier	Name of the database that contains the table that the trigger is defined on (always the current database)
event_object_schema	sql_identifier	Name of the schema that contains the table that the trigger is defined on
event_object_table	sql_identifier	Name of the table that the trigger is defined on
action_order	cardinal_number	Not yet implemented
action_condition	character_data	Applies to a feature not available in PostgreSQL
action_statement	character_data	Statement that is executed by the trigger (currently always <code>EXECUTE PROCEDURE function(...)</code> )

Name	Data Type	Description
action_orientation	character_data	Identifies whether the trigger fires once for each processed row or once for each statement (ROW or STATEMENT)
condition_timing	character_data	Time at which the trigger fires (BEFORE or AFTER)
condition_reference_old_table	table_identifier	Applies to a feature not available in PostgreSQL
condition_reference_new_table	table_identifier	Applies to a feature not available in PostgreSQL
condition_reference_old_row	sql_identifier	Applies to a feature not available in PostgreSQL
condition_reference_new_row	sql_identifier	Applies to a feature not available in PostgreSQL
created	time_stamp	Applies to a feature not available in PostgreSQL

Triggers in PostgreSQL have two incompatibilities with the SQL standard that affect the representation in the information schema. First, trigger names are local to the table in PostgreSQL, rather than being independent schema objects. Therefore there can be duplicate trigger names defined in one schema, as long as they belong to different tables. (`trigger_catalog` and `trigger_schema` are really the values pertaining to the table that the trigger is defined on.) Second, triggers can be defined to fire on multiple events in PostgreSQL (e.g., `ON INSERT OR UPDATE`), whereas the SQL standard only allows one. If a trigger is defined to fire on multiple events, it is represented as multiple rows in the information schema, one for each type of event. As a consequence of these two issues, the primary key of the view `triggers` is really (`trigger_catalog`, `trigger_schema`, `trigger_name`, `event_object_table`, `event_manipulation`) instead of (`trigger_catalog`, `trigger_schema`, `trigger_name`), which is what the SQL standard specifies. Nonetheless, if you define your triggers in a manner that conforms with the SQL standard (trigger names unique in the schema and only one event type per trigger), this will not affect you.

### 33.43. `usage_privileges`

The view `usage_privileges` is meant to identify `USAGE` privileges granted on various kinds of objects to a currently enabled role or by a currently enabled role. In PostgreSQL, this currently only applies to domains, and since domains do not have real privileges in PostgreSQL, this view shows implicit `USAGE` privileges granted to `PUBLIC` for all domains. In the future, this view might contain more useful information.

**Table 33-41. `usage_privileges` Columns**

Name	Data Type	Description
------	-----------	-------------

Name	Data Type	Description
grantor	sql_identifier	Currently set to the name of the owner of the object
grantee	sql_identifier	Currently always PUBLIC
object_catalog	sql_identifier	Name of the database containing the object (always the current database)
object_schema	sql_identifier	Name of the schema containing the object
object_name	sql_identifier	Name of the object
object_type	character_data	Currently always DOMAIN
privilege_type	character_data	Always USAGE
is_grantable	character_data	Currently always NO

## 33.44. view\_column\_usage

The view `view_column_usage` identifies all columns that are used in the query expression of a view (the `SELECT` statement that defines the view). A column is only included if the table that contains the column is owned by a currently enabled role.

**Note:** Columns of system tables are not included. This should be fixed sometime.

**Table 33-42. view\_column\_usage Columns**

Name	Data Type	Description
view_catalog	sql_identifier	Name of the database that contains the view (always the current database)
view_schema	sql_identifier	Name of the schema that contains the view
view_name	sql_identifier	Name of the view
table_catalog	sql_identifier	Name of the database that contains the table that contains the column that is used by the view (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table that contains the column that is used by the view

Name	Data Type	Description
table_name	sql_identifier	Name of the table that contains the column that is used by the view
column_name	sql_identifier	Name of the column that is used by the view

### 33.45. view\_routine\_usage

The view `view_routine_usage` identifies all routines (functions and procedures) that are used in the query expression of a view (the `SELECT` statement that defines the view). A routine is only included if that routine is owned by a currently enabled role.

**Table 33-43. view\_routine\_usage Columns**

Name	Data Type	Description
table_catalog	sql_identifier	Name of the database containing the view (always the current database)
table_schema	sql_identifier	Name of the schema containing the view
table_name	sql_identifier	Name of the view
specific_catalog	sql_identifier	Name of the database containing the function (always the current database)
specific_schema	sql_identifier	Name of the schema containing the function
specific_name	sql_identifier	The “specific name” of the function. See Section 33.29 for more information.

### 33.46. view\_table\_usage

The view `view_table_usage` identifies all tables that are used in the query expression of a view (the `SELECT` statement that defines the view). A table is only included if that table is owned by a currently enabled role.

**Note:** System tables are not included. This should be fixed sometime.

**Table 33-44. view\_table\_usage Columns**

Name	Data Type	Description
view_catalog	sql_identifier	Name of the database that contains the view (always the current database)
view_schema	sql_identifier	Name of the schema that contains the view
view_name	sql_identifier	Name of the view
table_catalog	sql_identifier	Name of the database that contains the table that is used by the view (always the current database)
table_schema	sql_identifier	Name of the schema that contains the table that is used by the view
table_name	sql_identifier	Name of the table that is used by the view

## 33.47. views

The view `views` contains all views defined in the current database. Only those views are shown that the current user has access to (by way of being the owner or having some privilege).

**Table 33-45. views Columns**

Name	Data Type	Description
table_catalog	sql_identifier	Name of the database that contains the view (always the current database)
table_schema	sql_identifier	Name of the schema that contains the view
table_name	sql_identifier	Name of the view
view_definition	character_data	Query expression defining the view (null if the view is not owned by a currently enabled role)
check_option	character_data	Applies to a feature not available in PostgreSQL
is_updatable	character_data	YES if the view is updatable (allows UPDATE and DELETE), NO if not

Name	Data Type	Description
is_insertable_into	character_data	YES if the view is insertable into (allows INSERT), NO if not

# V. Server Programming

This part is about extending the server functionality with user-defined functions, data types, triggers, etc. These are advanced topics which should probably be approached only after all the other user documentation about PostgreSQL has been understood. Later chapters in this part describe the server-side programming languages available in the PostgreSQL distribution as well as general issues concerning server-side programming languages. It is essential to read at least the earlier sections of Chapter 34 (covering functions) before diving into the material about server-side programming languages.

# Chapter 34. Extending SQL

In the sections that follow, we will discuss how you can extend the PostgreSQL SQL query language by adding:

- functions (starting in Section 34.3)
- aggregates (starting in Section 34.10)
- data types (starting in Section 34.11)
- operators (starting in Section 34.12)
- operator classes for indexes (starting in Section 34.14)

## 34.1. How Extensibility Works

PostgreSQL is extensible because its operation is catalog-driven. If you are familiar with standard relational database systems, you know that they store information about databases, tables, columns, etc., in what are commonly known as system catalogs. (Some systems call this the data dictionary.) The catalogs appear to the user as tables like any other, but the DBMS stores its internal bookkeeping in them. One key difference between PostgreSQL and standard relational database systems is that PostgreSQL stores much more information in its catalogs: not only information about tables and columns, but also information about data types, functions, access methods, and so on. These tables can be modified by the user, and since PostgreSQL bases its operation on these tables, this means that PostgreSQL can be extended by users. By comparison, conventional database systems can only be extended by changing hardcoded procedures in the source code or by loading modules specially written by the DBMS vendor.

The PostgreSQL server can moreover incorporate user-written code into itself through dynamic loading. That is, the user can specify an object code file (e.g., a shared library) that implements a new type or function, and PostgreSQL will load it as required. Code written in SQL is even more trivial to add to the server. This ability to modify its operation “on the fly” makes PostgreSQL uniquely suited for rapid prototyping of new applications and storage structures.

## 34.2. The PostgreSQL Type System

PostgreSQL data types are divided into base types, composite types, domains, and pseudo-types.

### 34.2.1. Base Types

Base types are those, like `int4`, that are implemented below the level of the SQL language (typically in a low-level language such as C). They generally correspond to what are often known as abstract data types. PostgreSQL can only operate on such types through functions provided by the user and only understands the behavior of such types to the extent that the user describes them. Base types are further subdivided into scalar and array types. For each scalar type, a corresponding array type is automatically created that can hold variable-size arrays of that scalar type.

### 34.2.2. Composite Types

Composite types, or row types, are created whenever the user creates a table. It is also possible to use *CREATE TYPE* to define a “stand-alone” composite type with no associated table. A composite type is simply a list of types with associated field names. A value of a composite type is a row or record of field values. The user can access the component fields from SQL queries. Refer to Section 8.15 for more information on composite types.

### 34.2.3. Domains

A domain is based on a particular base type and for many purposes is interchangeable with its base type. However, a domain can have constraints that restrict its valid values to a subset of what the underlying base type would allow.

Domains can be created using the SQL command *CREATE DOMAIN*. Their creation and use is not discussed in this chapter.

### 34.2.4. Pseudo-Types

There are a few “pseudo-types” for special purposes. Pseudo-types cannot appear as columns of tables or attributes of composite types, but they can be used to declare the argument and result types of functions. This provides a mechanism within the type system to identify special classes of functions. Table 8-20 lists the existing pseudo-types.

### 34.2.5. Polymorphic Types

Four pseudo-types of special interest are *anyelement*, *anyarray*, *anynonarray*, and *anyenum*, which are collectively called *polymorphic types*. Any function declared using these types is said to be a *polymorphic function*. A polymorphic function can operate on many different data types, with the specific data type(s) being determined by the data types actually passed to it in a particular call.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as *anyelement* is allowed to have any specific actual data type, but in any given call they must all be the *same* actual type. Each position declared as *anyarray* can have any array data type, but similarly they must all be the same type. If there are positions declared *anyarray* and others declared *anyelement*, the actual array type in the *anyarray* positions must be an array whose elements are the same type appearing in the *anyelement* positions. *anynonarray* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must not be an array type. *anyenum* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must be an enum type.

Thus, when more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as `equal(anyelement, anyelement)` will take any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the argument determines the actual

result type for that call. For example, if there were not already an array subscripting mechanism, one could define a function that implements subscripting as `subscript(anyarray, integer) returns anyelement`. This declaration constrains the actual first argument to be an array type, and allows the parser to infer the correct result type from the actual first argument's type. Another example is that a function declared as `f(anyarray) returns anyenum` will only accept arrays of enum types.

Note that `anynonarray` and `anyenum` do not represent separate type variables; they are the same type as `anyelement`, just with an additional constraint. For example, declaring a function as `f(anyelement, anyenum)` is equivalent to declaring it as `f(anyenum, anyenum)`: both actual arguments have to be the same enum type.

## 34.3. User-Defined Functions

PostgreSQL provides four kinds of functions:

- query language functions (functions written in SQL) (Section 34.4)
- procedural language functions (functions written in, for example, PL/pgSQL or PL/Tcl) (Section 34.7)
- internal functions (Section 34.8)
- C-language functions (Section 34.9)

Every kind of function can take base types, composite types, or combinations of these as arguments (parameters). In addition, every kind of function can return a base type or a composite type. Functions can also be defined to return sets of base or composite values.

Many kinds of functions can take or return certain pseudo-types (such as polymorphic types), but the available facilities vary. Consult the description of each kind of function for more details.

It's easiest to define SQL functions, so we'll start by discussing those. Most of the concepts presented for SQL functions will carry over to the other types of functions.

Throughout this chapter, it can be useful to look at the reference page of the *CREATE FUNCTION* command to understand the examples better. Some examples from this chapter can be found in `funcs.sql` and `funcs.c` in the `src/tutorial` directory in the PostgreSQL source distribution.

## 34.4. Query Language (SQL) Functions

SQL functions execute an arbitrary list of SQL statements, returning the result of the last query in the list. In the simple (non-set) case, the first row of the last query's result will be returned. (Bear in mind that "the first row" of a multirow result is not well-defined unless you use `ORDER BY`.) If the last query happens to return no rows at all, the null value will be returned.

Alternatively, an SQL function can be declared to return a set, by specifying the function's return type as `SETOF sometype`. In this case all rows of the last query's result are returned. Further details appear below.

The body of an SQL function must be a list of SQL statements separated by semicolons. A semicolon after the last statement is optional. Unless the function is declared to return `void`, the last statement must be a `SELECT`.

Any collection of commands in the SQL language can be packaged together and defined as a function. Besides `SELECT` queries, the commands can include data modification queries (`INSERT`, `UPDATE`, and `DELETE`), as well as other SQL commands. (The only exception is that you cannot put `BEGIN`, `COMMIT`, `ROLLBACK`, or `SAVEPOINT` commands into a SQL function.) However, the final command must be a `SELECT` that returns whatever is specified as the function's return type. Alternatively, if you want to define a SQL function that performs actions but has no useful value to return, you can define it as returning `void`. In that case, the function body must not end with a `SELECT`. For example, this function removes rows with negative salaries from the `emp` table:

```
CREATE FUNCTION clean_emp() RETURNS void AS '
    DELETE FROM emp
        WHERE salary < 0;
' LANGUAGE SQL;

SELECT clean_emp();

clean_emp
-----

(1 row)
```

The syntax of the `CREATE FUNCTION` command requires the function body to be written as a string constant. It is usually most convenient to use dollar quoting (see Section 4.1.2.2) for the string constant. If you choose to use regular single-quoted string constant syntax, you must double single quote marks (') and backslashes (\) (assuming escape string syntax) in the body of the function (see Section 4.1.2.1).

Arguments to the SQL function are referenced in the function body using the syntax `$n`: `$1` refers to the first argument, `$2` to the second, and so on. If an argument is of a composite type, then the dot notation, e.g., `$1.name`, can be used to access attributes of the argument. The arguments can only be used as data values, not as identifiers. Thus for example this is reasonable:

```
INSERT INTO mytable VALUES ($1);
```

but this will not work:

```
INSERT INTO $1 VALUES (42);
```

### 34.4.1. SQL Functions on Base Types

The simplest possible SQL function has no arguments and simply returns a base type, such as `integer`:

```
CREATE FUNCTION one() RETURNS integer AS $$
    SELECT 1 AS result;
$$ LANGUAGE SQL;
```

```
-- Alternative syntax for string literal:
CREATE FUNCTION one() RETURNS integer AS '
    SELECT 1 AS result;
' LANGUAGE SQL;
```

```
SELECT one();
```

```
one
-----
1
```

Notice that we defined a column alias within the function body for the result of the function (with the name `result`), but this column alias is not visible outside the function. Hence, the result is labeled `one` instead of `result`.

It is almost as easy to define SQL functions that take base types as arguments. In the example below, notice how we refer to the arguments within the function as `$1` and `$2`.

```
CREATE FUNCTION add_em(integer, integer) RETURNS integer AS $$
    SELECT $1 + $2;
$$ LANGUAGE SQL;
```

```
SELECT add_em(1, 2) AS answer;
```

```
answer
-----
3
```

Here is a more useful function, which might be used to debit a bank account:

```
CREATE FUNCTION tf1 (integer, numeric) RETURNS integer AS $$
    UPDATE bank
        SET balance = balance - $2
        WHERE accountno = $1;
    SELECT 1;
$$ LANGUAGE SQL;
```

A user could execute this function to debit account 17 by \$100.00 as follows:

```
SELECT tf1(17, 100.0);
```

In practice one would probably like a more useful result from the function than a constant 1, so a more likely definition is:

```
CREATE FUNCTION tf1 (integer, numeric) RETURNS numeric AS $$
    UPDATE bank
        SET balance = balance - $2
        WHERE accountno = $1;
```

```
SELECT balance FROM bank WHERE accountno = $1;
$$ LANGUAGE SQL;
```

which adjusts the balance and returns the new balance.

### 34.4.2. SQL Functions on Composite Types

When writing functions with arguments of composite types, we must not only specify which argument we want (as we did above with `$1` and `$2`) but also the desired attribute (field) of that argument. For example, suppose that `emp` is a table containing employee data, and therefore also the name of the composite type of each row of the table. Here is a function `double_salary` that computes what someone's salary would be if it were doubled:

```
CREATE TABLE emp (
    name      text,
    salary    numeric,
    age       integer,
    cubicle   point
);

CREATE FUNCTION double_salary(emp) RETURNS numeric AS $$
    SELECT $1.salary * 2 AS salary;
$$ LANGUAGE SQL;

SELECT name, double_salary(emp.*) AS dream
FROM emp
WHERE emp.cubicle ~= point '(2,1)';

name | dream
-----+-----
Bill |  8400
```

Notice the use of the syntax `$1.salary` to select one field of the argument row value. Also notice how the calling `SELECT` command uses `*` to select the entire current row of a table as a composite value. The table row can alternatively be referenced using just the table name, like this:

```
SELECT name, double_salary(emp) AS dream
FROM emp
WHERE emp.cubicle ~= point '(2,1)';
```

but this usage is deprecated since it's easy to get confused.

Sometimes it is handy to construct a composite argument value on-the-fly. This can be done with the `ROW` construct. For example, we could adjust the data being passed to the function:

```
SELECT name, double_salary(ROW(name, salary*1.1, age, cubicle)) AS dream
FROM emp;
```

It is also possible to build a function that returns a composite type. This is an example of a function that returns a single `emp` row:

```
CREATE FUNCTION new_emp() RETURNS emp AS $$
    SELECT text 'None' AS name,
           1000.0 AS salary,
           25 AS age,
           point '(2,2)' AS cubicle;
$$ LANGUAGE SQL;
```

In this example we have specified each of the attributes with a constant value, but any computation could have been substituted for these constants.

Note two important things about defining the function:

- The select list order in the query must be exactly the same as that in which the columns appear in the table associated with the composite type. (Naming the columns, as we did above, is irrelevant to the system.)
- You must typecast the expressions to match the definition of the composite type, or you will get errors like this:

```
ERROR: function declared to return emp returns varchar instead of text at column 1
```

A different way to define the same function is:

```
CREATE FUNCTION new_emp() RETURNS emp AS $$
    SELECT ROW('None', 1000.0, 25, '(2,2)')::emp;
$$ LANGUAGE SQL;
```

Here we wrote a `SELECT` that returns just a single column of the correct composite type. This isn't really better in this situation, but it is a handy alternative in some cases — for example, if we need to compute the result by calling another function that returns the desired composite value.

We could call this function directly in either of two ways:

```
SELECT new_emp();

      new_emp
-----
(None,1000.0,25,"(2,2)")

SELECT * FROM new_emp();

 name | salary | age | cubicle
-----+-----+-----+-----
None  | 1000.0 | 25  | (2,2)
```

The second way is described more fully in Section 34.4.4.

When you use a function that returns a composite type, you might want only one field (attribute) from its result. You can do that with syntax like this:

```
SELECT (new_emp()).name;
```

```

name
-----
None

```

The extra parentheses are needed to keep the parser from getting confused. If you try to do it without them, you get something like this:

```

SELECT new_emp().name;
ERROR:  syntax error at or near "." at character 17
LINE 1: SELECT new_emp().name;
                ^

```

Another option is to use functional notation for extracting an attribute. The simple way to explain this is that we can use the notations `attribute(table)` and `table.attribute` interchangeably.

```

SELECT name(new_emp());

name
-----
None

-- This is the same as:
-- SELECT emp.name AS youngster FROM emp WHERE emp.age < 30;

SELECT name(emp) AS youngster FROM emp WHERE age(emp) < 30;

youngster
-----
Sam
Andy

```

**Tip:** The equivalence between functional notation and attribute notation makes it possible to use functions on composite types to emulate “computed fields”. For example, using the previous definition for `double_salary(emp)`, we can write

```
SELECT emp.name, emp.double_salary FROM emp;
```

An application using this wouldn't need to be directly aware that `double_salary` isn't a real column of the table. (You can also emulate computed fields with views.)

Another way to use a function returning a composite type is to pass the result to another function that accepts the correct row type as input:

```

CREATE FUNCTION getname(emp) RETURNS text AS $$
    SELECT $1.name;
$$ LANGUAGE SQL;

SELECT getname(new_emp());

```

```

getname
-----
None
(1 row)

```

Still another way to use a function that returns a composite type is to call it as a table function, as described in Section 34.4.4.

### 34.4.3. Functions with Output Parameters

An alternative way of describing a function's results is to define it with *output parameters*, as in this example:

```

CREATE FUNCTION add_em (IN x int, IN y int, OUT sum int)
AS 'SELECT $1 + $2'
LANGUAGE SQL;

SELECT add_em(3,7);
 add_em
-----
      10
(1 row)

```

This is not essentially different from the version of `add_em` shown in Section 34.4.1. The real value of output parameters is that they provide a convenient way of defining functions that return several columns. For example,

```

CREATE FUNCTION sum_n_product (x int, y int, OUT sum int, OUT product int)
AS 'SELECT $1 + $2, $1 * $2'
LANGUAGE SQL;

SELECT * FROM sum_n_product(11,42);
 sum | product
-----+-----
   53 |    462
(1 row)

```

What has essentially happened here is that we have created an anonymous composite type for the result of the function. The above example has the same end result as

```

CREATE TYPE sum_prod AS (sum int, product int);

CREATE FUNCTION sum_n_product (int, int) RETURNS sum_prod
AS 'SELECT $1 + $2, $1 * $2'
LANGUAGE SQL;

```

but not having to bother with the separate composite type definition is often handy.

Notice that output parameters are not included in the calling argument list when invoking such a function from SQL. This is because PostgreSQL considers only the input parameters to define the function's call-

ing signature. That means also that only the input parameters matter when referencing the function for purposes such as dropping it. We could drop the above function with either of

```
DROP FUNCTION sum_n_product (x int, y int, OUT sum int, OUT product int);
DROP FUNCTION sum_n_product (int, int);
```

Parameters can be marked as `IN` (the default), `OUT`, or `INOUT`. An `INOUT` parameter serves as both an input parameter (part of the calling argument list) and an output parameter (part of the result record type).

### 34.4.4. SQL Functions as Table Sources

All SQL functions can be used in the `FROM` clause of a query, but it is particularly useful for functions returning composite types. If the function is defined to return a base type, the table function produces a one-column table. If the function is defined to return a composite type, the table function produces a column for each attribute of the composite type.

Here is an example:

```
CREATE TABLE foo (fooid int, foosubid int, fooname text);
INSERT INTO foo VALUES (1, 1, 'Joe');
INSERT INTO foo VALUES (1, 2, 'Ed');
INSERT INTO foo VALUES (2, 1, 'Mary');
```

```
CREATE FUNCTION getfoo(int) RETURNS foo AS $$
    SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;
```

```
SELECT *, upper(fooname) FROM getfoo(1) AS t1;
```

```

fooid | foosubid | fooname | upper
-----+-----+-----+-----
      1 |         1 | Joe     | JOE
(1 row)
```

As the example shows, we can work with the columns of the function's result just the same as if they were columns of a regular table.

Note that we only got one row out of the function. This is because we did not use `SETOF`. That is described in the next section.

### 34.4.5. SQL Functions Returning Sets

When an SQL function is declared as returning `SETOF sometype`, the function's final `SELECT` query is executed to completion, and each row it outputs is returned as an element of the result set.

This feature is normally used when calling the function in the `FROM` clause. In this case each row returned by the function becomes a row of the table seen by the query. For example, assume that table `foo` has the same contents as above, and we say:

```
CREATE FUNCTION getfoo(int) RETURNS SETOF foo AS $$
    SELECT * FROM foo WHERE fooid = $1;
$$ LANGUAGE SQL;

SELECT * FROM getfoo(1) AS t1;
```

Then we would get:

```
fooid | foosubid | fooname
-----+-----+-----
      1 |          1 | Joe
      1 |          2 | Ed
(2 rows)
```

It is also possible to return multiple rows with the columns defined by output parameters, like this:

```
CREATE FUNCTION sum_n_product_with_tab (x int, OUT sum int, OUT product int) RETURNS SETOF
    SELECT x + tab.y, x * tab.y FROM tab;
$$ LANGUAGE SQL;
```

The key point here is that you must write `RETURNS SETOF record` to indicate that the function returns multiple rows instead of just one. If there is only one output parameter, write that parameter's type instead of `record`.

Currently, functions returning sets can also be called in the select list of a query. For each row that the query generates by itself, the function returning set is invoked, and an output row is generated for each element of the function's result set. Note, however, that this capability is deprecated and might be removed in future releases. The following is an example function returning a set from the select list:

```
CREATE FUNCTION listchildren(text) RETURNS SETOF text AS $$
    SELECT name FROM nodes WHERE parent = $1
$$ LANGUAGE SQL;
```

```
SELECT * FROM nodes;
   name   | parent
-----+-----
   Top    |
 Child1   | Top
 Child2   | Top
 Child3   | Top
 SubChild1 | Child1
 SubChild2 | Child1
(6 rows)
```

```
SELECT listchildren('Top');
 listchildren
-----
 Child1
 Child2
 Child3
(3 rows)
```

```

SELECT name, listchildren(name) FROM nodes;
   name | listchildren
-----+-----
   Top  | Child1
   Top  | Child2
   Top  | Child3
Child1  | SubChild1
Child1  | SubChild2
(5 rows)

```

In the last `SELECT`, notice that no output row appears for `Child2`, `Child3`, etc. This happens because `listchildren` returns an empty set for those arguments, so no result rows are generated.

### 34.4.6. Polymorphic SQL Functions

SQL functions can be declared to accept and return the polymorphic types `anyelement`, `anyarray`, `anynonarray`, and `anyenum`. See Section 34.2.5 for a more detailed explanation of polymorphic functions. Here is a polymorphic function `make_array` that builds up an array from two arbitrary data type elements:

```

CREATE FUNCTION make_array(anyelement, anyelement) RETURNS anyarray AS $$
    SELECT ARRAY[$1, $2];
$$ LANGUAGE SQL;

SELECT make_array(1, 2) AS intarray, make_array('a'::text, 'b') AS textarray;
   intarray | textarray
-----+-----
   {1,2}   | {a,b}
(1 row)

```

Notice the use of the typecast `'a'::text` to specify that the argument is of type `text`. This is required if the argument is just a string literal, since otherwise it would be treated as type `unknown`, and array of `unknown` is not a valid type. Without the typecast, you will get errors like this:

```

ERROR:  could not determine polymorphic type because input has type "unknown"

```

It is permitted to have polymorphic arguments with a fixed return type, but the converse is not. For example:

```

CREATE FUNCTION is_greater(anyelement, anyelement) RETURNS boolean AS $$
    SELECT $1 > $2;
$$ LANGUAGE SQL;

SELECT is_greater(1, 2);
   is_greater
-----
   f
(1 row)

```

```
CREATE FUNCTION invalid_func() RETURNS anyelement AS $$
    SELECT 1;
$$ LANGUAGE SQL;
ERROR:  cannot determine result data type
DETAIL:  A function returning a polymorphic type must have at least one polymorphic argument
```

Polymorphism can be used with functions that have output arguments. For example:

```
CREATE FUNCTION dup (f1 anyelement, OUT f2 anyelement, OUT f3 anyarray)
AS 'select $1, array[$1,$1]' LANGUAGE sql;

SELECT * FROM dup(22);
 f2 |    f3
----+-----
 22 | {22,22}
(1 row)
```

## 34.5. Function Overloading

More than one function can be defined with the same SQL name, so long as the arguments they take are different. In other words, function names can be *overloaded*. When a query is executed, the server will determine which function to call from the data types and the number of the provided arguments. Overloading can also be used to simulate functions with a variable number of arguments, up to a finite maximum number.

When creating a family of overloaded functions, one should be careful not to create ambiguities. For instance, given the functions:

```
CREATE FUNCTION test(int, real) RETURNS ...
CREATE FUNCTION test(smallint, double precision) RETURNS ...
```

it is not immediately clear which function would be called with some trivial input like `test(1, 1.5)`. The currently implemented resolution rules are described in Chapter 10, but it is unwise to design a system that subtly relies on this behavior.

A function that takes a single argument of a composite type should generally not have the same name as any attribute (field) of that type. Recall that `attribute(table)` is considered equivalent to `table.attribute`. In the case that there is an ambiguity between a function on a composite type and an attribute of the composite type, the attribute will always be used. It is possible to override that choice by schema-qualifying the function name (that is, `schema.func(table)`) but it's better to avoid the problem by not choosing conflicting names.

When overloading C-language functions, there is an additional constraint: The C name of each function in the family of overloaded functions must be different from the C names of all other functions, either internal or dynamically loaded. If this rule is violated, the behavior is not portable. You might get a run-time linker error, or one of the functions will get called (usually the internal one). The alternative form

of the `AS` clause for the `SQL CREATE FUNCTION` command decouples the SQL function name from the function name in the C source code. For instance:

```
CREATE FUNCTION test(int) RETURNS int
    AS 'filename', 'test_larg'
    LANGUAGE C;
CREATE FUNCTION test(int, int) RETURNS int
    AS 'filename', 'test_2arg'
    LANGUAGE C;
```

The names of the C functions here reflect one of many possible conventions.

## 34.6. Function Volatility Categories

Every function has a *volatility* classification, with the possibilities being `VOLATILE`, `STABLE`, or `IMMUTABLE`. `VOLATILE` is the default if the `CREATE FUNCTION` command does not specify a category. The volatility category is a promise to the optimizer about the behavior of the function:

- A `VOLATILE` function can do anything, including modifying the database. It can return different results on successive calls with the same arguments. The optimizer makes no assumptions about the behavior of such functions. A query using a volatile function will re-evaluate the function at every row where its value is needed.
- A `STABLE` function cannot modify the database and is guaranteed to return the same results given the same arguments for all rows within a single statement. This category allows the optimizer to optimize multiple calls of the function to a single call. In particular, it is safe to use an expression containing such a function in an index scan condition. (Since an index scan will evaluate the comparison value only once, not once at each row, it is not valid to use a `VOLATILE` function in an index scan condition.)
- An `IMMUTABLE` function cannot modify the database and is guaranteed to return the same results given the same arguments forever. This category allows the optimizer to pre-evaluate the function when a query calls it with constant arguments. For example, a query like `SELECT ... WHERE x = 2 + 2` can be simplified on sight to `SELECT ... WHERE x = 4`, because the function underlying the integer addition operator is marked `IMMUTABLE`.

For best optimization results, you should label your functions with the strictest volatility category that is valid for them.

Any function with side-effects *must* be labeled `VOLATILE`, so that calls to it cannot be optimized away. Even a function with no side-effects needs to be labeled `VOLATILE` if its value can change within a single query; some examples are `random()`, `curval()`, `timeofday()`.

There is relatively little difference between `STABLE` and `IMMUTABLE` categories when considering simple interactive queries that are planned and immediately executed: it doesn't matter a lot whether a function is executed once during planning or once during query execution startup. But there is a big difference if the plan is saved and reused later. Labeling a function `IMMUTABLE` when it really isn't might allow it to be prematurely folded to a constant during planning, resulting in a stale value being re-used during

subsequent uses of the plan. This is a hazard when using prepared statements or when using function languages that cache plans (such as PL/pgSQL).

Because of the snapshotting behavior of MVCC (see Chapter 13) a function containing only `SELECT` commands can safely be marked `STABLE`, even if it selects from tables that might be undergoing modifications by concurrent queries. PostgreSQL will execute a `STABLE` function using the snapshot established for the calling query, and so it will see a fixed view of the database throughout that query. Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

The same snapshotting behavior is used for `SELECT` commands within `IMMUTABLE` functions. It is generally unwise to select from database tables within an `IMMUTABLE` function at all, since the immutability will be broken if the table contents ever change. However, PostgreSQL does not enforce that you do not do that.

A common error is to label a function `IMMUTABLE` when its results depend on a configuration parameter. For example, a function that manipulates timestamps might well have results that depend on the timezone setting. For safety, such functions should be labeled `STABLE` instead.

**Note:** Before PostgreSQL release 8.0, the requirement that `STABLE` and `IMMUTABLE` functions cannot modify the database was not enforced by the system. Release 8.0 enforces it by requiring SQL functions and procedural language functions of these categories to contain no SQL commands other than `SELECT`. (This is not a completely bulletproof test, since such functions could still call `VOLATILE` functions that modify the database. If you do that, you will find that the `STABLE` or `IMMUTABLE` function does not notice the database changes applied by the called function.)

## 34.7. Procedural Language Functions

PostgreSQL allows user-defined functions to be written in other languages besides SQL and C. These other languages are generically called *procedural languages* (PLs). Procedural languages aren't built into the PostgreSQL server; they are offered by loadable modules. See Chapter 37 and following chapters for more information.

## 34.8. Internal Functions

Internal functions are functions written in C that have been statically linked into the PostgreSQL server. The “body” of the function definition specifies the C-language name of the function, which need not be the same as the name being declared for SQL use. (For reasons of backwards compatibility, an empty body is accepted as meaning that the C-language function name is the same as the SQL name.)

Normally, all internal functions present in the server are declared during the initialization of the database cluster (`initdb`), but a user could use `CREATE FUNCTION` to create additional alias names for an internal function. Internal functions are declared in `CREATE FUNCTION` with language name `internal`. For instance, to create an alias for the `sqrt` function:

```
CREATE FUNCTION square_root(double precision) RETURNS double precision
```

```
AS 'dsqrt'
LANGUAGE internal
STRICT;
```

(Most internal functions expect to be declared “strict”.)

**Note:** Not all “predefined” functions are “internal” in the above sense. Some predefined functions are written in SQL.

## 34.9. C-Language Functions

User-defined functions can be written in C (or a language that can be made compatible with C, such as C++). Such functions are compiled into dynamically loadable objects (also called shared libraries) and are loaded by the server on demand. The dynamic loading feature is what distinguishes “C language” functions from “internal” functions — the actual coding conventions are essentially the same for both. (Hence, the standard internal function library is a rich source of coding examples for user-defined C functions.)

Two different calling conventions are currently used for C functions. The newer “version 1” calling convention is indicated by writing a `PG_FUNCTION_INFO_V1()` macro call for the function, as illustrated below. Lack of such a macro indicates an old-style (“version 0”) function. The language name specified in `CREATE FUNCTION` is C in either case. Old-style functions are now deprecated because of portability problems and lack of functionality, but they are still supported for compatibility reasons.

### 34.9.1. Dynamic Loading

The first time a user-defined function in a particular loadable object file is called in a session, the dynamic loader loads that object file into memory so that the function can be called. The `CREATE FUNCTION` for a user-defined C function must therefore specify two pieces of information for the function: the name of the loadable object file, and the C name (link symbol) of the specific function to call within that object file. If the C name is not explicitly specified then it is assumed to be the same as the SQL function name.

The following algorithm is used to locate the shared object file based on the name given in the `CREATE FUNCTION` command:

1. If the name is an absolute path, the given file is loaded.
2. If the name starts with the string `$libdir`, that part is replaced by the PostgreSQL package library directory name, which is determined at build time.
3. If the name does not contain a directory part, the file is searched for in the path specified by the configuration variable `dynamic_library_path`.
4. Otherwise (the file was not found in the path, or it contains a non-absolute directory part), the dynamic loader will try to take the name as given, which will most likely fail. (It is unreliable to depend on the current working directory.)

If this sequence does not work, the platform-specific shared library file name extension (often `.so`) is appended to the given name and this sequence is tried again. If that fails as well, the load will fail.

It is recommended to locate shared libraries either relative to `$libdir` or through the dynamic library path. This simplifies version upgrades if the new installation is at a different location. The actual directory that `$libdir` stands for can be found out with the command `pg_config --pkglibdir`.

The user ID the PostgreSQL server runs as must be able to traverse the path to the file you intend to load. Making the file or a higher-level directory not readable and/or not executable by the `postgres` user is a common mistake.

In any case, the file name that is given in the `CREATE FUNCTION` command is recorded literally in the system catalogs, so if the file needs to be loaded again the same procedure is applied.

**Note:** PostgreSQL will not compile a C function automatically. The object file must be compiled before it is referenced in a `CREATE FUNCTION` command. See Section 34.9.6 for additional information.

To ensure that a dynamically loaded object file is not loaded into an incompatible server, PostgreSQL checks that the file contains a “magic block” with the appropriate contents. This allows the server to detect obvious incompatibilities, such as code compiled for a different major version of PostgreSQL. A magic block is required as of PostgreSQL 8.2. To include a magic block, write this in one (and only one) of the module source files, after having included the header `fmgr.h`:

```
#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif
```

The `#ifdef` test can be omitted if the code doesn’t need to compile against pre-8.2 PostgreSQL releases.

After it is used for the first time, a dynamically loaded object file is retained in memory. Future calls in the same session to the function(s) in that file will only incur the small overhead of a symbol table lookup. If you need to force a reload of an object file, for example after recompiling it, use the `LOAD` command or begin a fresh session.

Optionally, a dynamically loaded file can contain initialization and finalization functions. If the file includes a function named `_PG_init`, that function will be called immediately after loading the file. The function receives no parameters and should return void. If the file includes a function named `_PG_fini`, that function will be called immediately before unloading the file. Likewise, the function receives no parameters and should return void. Note that `_PG_fini` will only be called during an unload of the file, not during process termination. (Presently, an unload only happens in the context of re-loading the file due to an explicit `LOAD` command.)

## 34.9.2. Base Types in C-Language Functions

To know how to write C-language functions, you need to know how PostgreSQL internally represents base data types and how they can be passed to and from functions. Internally, PostgreSQL regards a base type as a “blob of memory”. The user-defined functions that you define over a type in turn define the way that PostgreSQL can operate on it. That is, PostgreSQL will only store and retrieve the data from disk and use your user-defined functions to input, process, and output the data.

Base types can have one of three internal formats:

- pass by value, fixed-length
- pass by reference, fixed-length
- pass by reference, variable-length

By-value types can only be 1, 2, or 4 bytes in length (also 8 bytes, if `sizeof(Datum)` is 8 on your machine). You should be careful to define your types such that they will be the same size (in bytes) on all architectures. For example, the `long` type is dangerous because it is 4 bytes on some machines and 8 bytes on others, whereas `int` type is 4 bytes on most Unix machines. A reasonable implementation of the `int4` type on Unix machines might be:

```
/* 4-byte integer, passed by value */
typedef int int4;
```

On the other hand, fixed-length types of any size can be passed by-reference. For example, here is a sample implementation of a PostgreSQL type:

```
/* 16-byte structure, passed by reference */
typedef struct
{
    double x, y;
} Point;
```

Only pointers to such types can be used when passing them in and out of PostgreSQL functions. To return a value of such a type, allocate the right amount of memory with `palloc`, fill in the allocated memory, and return a pointer to it. (Also, if you just want to return the same value as one of your input arguments that's of the same data type, you can skip the extra `palloc` and just return the pointer to the input value.)

Finally, all variable-length types must also be passed by reference. All variable-length types must begin with a length field of exactly 4 bytes, and all data to be stored within that type must be located in the memory immediately following that length field. The length field contains the total length of the structure, that is, it includes the size of the length field itself.

### Warning

*Never* modify the contents of a pass-by-reference input value. If you do so you are likely to corrupt on-disk data, since the pointer you are given might point directly into a disk buffer. The sole exception to this rule is explained in Section 34.10.

As an example, we can define the type `text` as follows:

```
typedef struct {
    int4 length;
    char data[1];
} text;
```

Obviously, the data field declared here is not long enough to hold all possible strings. Since it's impossible to declare a variable-size structure in C, we rely on the knowledge that the C compiler won't range-check array subscripts. We just allocate the necessary amount of space and then access the array as if it were declared the right length. (This is a common trick, which you can read about in many textbooks about C.)

When manipulating variable-length types, we must be careful to allocate the correct amount of memory and set the length field correctly. For example, if we wanted to store 40 bytes in a `text` structure, we might use a code fragment like this:

```
#include "postgres.h"
...
char buffer[40]; /* our source data */
...
text *destination = (text *) palloc(VARHDRSZ + 40);
destination->length = VARHDRSZ + 40;
memcpy(destination->data, buffer, 40);
...
```

`VARHDRSZ` is the same as `sizeof(int4)`, but it's considered good style to use the macro `VARHDRSZ` to refer to the size of the overhead for a variable-length type.

Table 34-1 specifies which C type corresponds to which SQL type when writing a C-language function that uses a built-in type of PostgreSQL. The "Defined In" column gives the header file that needs to be included to get the type definition. (The actual definition might be in a different file that is included by the listed file. It is recommended that users stick to the defined interface.) Note that you should always include `postgres.h` first in any source file, because it declares a number of things that you will need anyway.

**Table 34-1. Equivalent C Types for Built-In SQL Types**

SQL Type	C Type	Defined In
<code>abstime</code>	<code>AbsoluteTime</code>	<code>utils/nabstime.h</code>
<code>boolean</code>	<code>bool</code>	<code>postgres.h</code> (maybe compiler built-in)
<code>box</code>	<code>BOX*</code>	<code>utils/geo_decls.h</code>
<code>bytea</code>	<code>bytea*</code>	<code>postgres.h</code>
<code>"char"</code>	<code>char</code>	(compiler built-in)
<code>character</code>	<code>BpChar*</code>	<code>postgres.h</code>
<code>cid</code>	<code>CommandId</code>	<code>postgres.h</code>
<code>date</code>	<code>DateADT</code>	<code>utils/date.h</code>
<code>smallint (int2)</code>	<code>int2</code> or <code>int16</code>	<code>postgres.h</code>
<code>int2vector</code>	<code>int2vector*</code>	<code>postgres.h</code>
<code>integer (int4)</code>	<code>int4</code> or <code>int32</code>	<code>postgres.h</code>
<code>real (float4)</code>	<code>float4*</code>	<code>postgres.h</code>
<code>double precision (float8)</code>	<code>float8*</code>	<code>postgres.h</code>
<code>interval</code>	<code>Interval*</code>	<code>utils/timestamp.h</code>
<code>lseg</code>	<code>LSEG*</code>	<code>utils/geo_decls.h</code>

SQL Type	C Type	Defined In
name	Name	postgres.h
oid	Oid	postgres.h
oidvector	oidvector*	postgres.h
path	PATH*	utils/geo_decls.h
point	POINT*	utils/geo_decls.h
regproc	regproc	postgres.h
reltime	RelativeTime	utils/nabstime.h
text	text*	postgres.h
tid	ItemPointer	storage/itemptr.h
time	TimeADT	utils/date.h
time with time zone	TimeTzADT	utils/date.h
timestamp	Timestamp*	utils/timestamp.h
tinterval	TimeInterval	utils/nabstime.h
varchar	VarChar*	postgres.h
xid	TransactionId	postgres.h

Now that we've gone over all of the possible structures for base types, we can show some examples of real functions.

### 34.9.3. Version 0 Calling Conventions

We present the “old style” calling convention first — although this approach is now deprecated, it's easier to get a handle on initially. In the version-0 method, the arguments and result of the C function are just declared in normal C style, but being careful to use the C representation of each SQL data type as shown above.

Here are some examples:

```
#include "postgres.h"
#include <string.h>

/* by value */

int
add_one(int arg)
{
    return arg + 1;
}

/* by reference, fixed length */

float8 *
add_one_float8(float8 *arg)
{
    float8    *result = (float8 *) palloc(sizeof(float8));
```

```

    *result = *arg + 1.0;

    return result;
}

Point *
makepoint(Point *pointx, Point *pointy)
{
    Point      *new_point = (Point *) malloc(sizeof(Point));

    new_point->x = pointx->x;
    new_point->y = pointy->y;

    return new_point;
}

/* by reference, variable length */

text *
copytext(text *t)
{
    /*
     * VARSIZE is the total size of the struct in bytes.
     */
    text *new_t = (text *) malloc(VARSIZE(t));
    SET_VARSIZE(new_t, VARSIZE(t));
    /*
     * VARDATA is a pointer to the data region of the struct.
     */
    memcpy((void *) VARDATA(new_t), /* destination */
           (void *) VARDATA(t),    /* source */
           VARSIZE(t) - VARHDRSZ); /* how many bytes */
    return new_t;
}

text *
concat_text(text *arg1, text *arg2)
{
    int32 new_text_size = VARSIZE(arg1) + VARSIZE(arg2) - VARHDRSZ;
    text *new_text = (text *) malloc(new_text_size);

    SET_VARSIZE(new_text, new_text_size);
    memcpy(VARDATA(new_text), VARDATA(arg1), VARSIZE(arg1) - VARHDRSZ);
    memcpy(VARDATA(new_text) + (VARSIZE(arg1) - VARHDRSZ),
           VARDATA(arg2), VARSIZE(arg2) - VARHDRSZ);
    return new_text;
}

```

Supposing that the above code has been prepared in file `funcs.c` and compiled into a shared object, we could define the functions to PostgreSQL with commands like this:

```

CREATE FUNCTION add_one(integer) RETURNS integer
    AS 'DIRECTORY/funcs', 'add_one'
    LANGUAGE C STRICT;

-- note overloading of SQL function name "add_one"
CREATE FUNCTION add_one(double precision) RETURNS double precision
    AS 'DIRECTORY/funcs', 'add_one_float8'
    LANGUAGE C STRICT;

CREATE FUNCTION makepoint(point, point) RETURNS point
    AS 'DIRECTORY/funcs', 'makepoint'
    LANGUAGE C STRICT;

CREATE FUNCTION copytext(text) RETURNS text
    AS 'DIRECTORY/funcs', 'copytext'
    LANGUAGE C STRICT;

CREATE FUNCTION concat_text(text, text) RETURNS text
    AS 'DIRECTORY/funcs', 'concat_text'
    LANGUAGE C STRICT;

```

Here, *DIRECTORY* stands for the directory of the shared library file (for instance the PostgreSQL tutorial directory, which contains the code for the examples used in this section). (Better style would be to use just *'funcs'* in the *AS* clause, after having added *DIRECTORY* to the search path. In any case, we can omit the system-specific extension for a shared library, commonly *.so* or *.sl*.)

Notice that we have specified the functions as “strict”, meaning that the system should automatically assume a null result if any input value is null. By doing this, we avoid having to check for null inputs in the function code. Without this, we’d have to check for null values explicitly, by checking for a null pointer for each pass-by-reference argument. (For pass-by-value arguments, we don’t even have a way to check!)

Although this calling convention is simple to use, it is not very portable; on some architectures there are problems with passing data types that are smaller than *int* this way. Also, there is no simple way to return a null result, nor to cope with null arguments in any way other than making the function strict. The version-1 convention, presented next, overcomes these objections.

### 34.9.4. Version 1 Calling Conventions

The version-1 calling convention relies on macros to suppress most of the complexity of passing arguments and results. The C declaration of a version-1 function is always:

```
Datum funcname(PG_FUNCTION_ARGS)
```

In addition, the macro call:

```
PG_FUNCTION_INFO_V1(funcname);
```

must appear in the same source file. (Conventionally, it's written just before the function itself.) This macro call is not needed for `internal-language` functions, since PostgreSQL assumes that all internal functions use the version-1 convention. It is, however, required for dynamically-loaded functions.

In a version-1 function, each actual argument is fetched using a `PG_GETARG_xxx()` macro that corresponds to the argument's data type, and the result is returned using a `PG_RETURN_xxx()` macro for the return type. `PG_GETARG_xxx()` takes as its argument the number of the function argument to fetch, where the count starts at 0. `PG_RETURN_xxx()` takes as its argument the actual value to return.

Here we show the same functions as above, coded in version-1 style:

```
#include "postgres.h"
#include <string.h>
#include "fmgr.h"

/* by value */

PG_FUNCTION_INFO_V1(add_one);

Datum
add_one(PG_FUNCTION_ARGS)
{
    int32    arg = PG_GETARG_INT32(0);

    PG_RETURN_INT32(arg + 1);
}

/* by reference, fixed length */

PG_FUNCTION_INFO_V1(add_one_float8);

Datum
add_one_float8(PG_FUNCTION_ARGS)
{
    /* The macros for FLOAT8 hide its pass-by-reference nature. */
    float8   arg = PG_GETARG_FLOAT8(0);

    PG_RETURN_FLOAT8(arg + 1.0);
}

PG_FUNCTION_INFO_V1(makepoint);

Datum
makepoint(PG_FUNCTION_ARGS)
{
    /* Here, the pass-by-reference nature of Point is not hidden. */
    Point    *pointx = PG_GETARG_POINT_P(0);
    Point    *pointy = PG_GETARG_POINT_P(1);
    Point    *new_point = (Point *) palloc(sizeof(Point));

    new_point->x = pointx->x;
    new_point->y = pointy->y;
```

```

    PG_RETURN_POINT_P(new_point);
}

/* by reference, variable length */

PG_FUNCTION_INFO_V1(copytext);

Datum
copytext(PG_FUNCTION_ARGS)
{
    text      *t = PG_GETARG_TEXT_P(0);
    /*
     * VARSIZE is the total size of the struct in bytes.
     */
    text      *new_t = (text *) palloc(VARSIZE(t));
    SET_VARSIZE(new_t, VARSIZE(t));
    /*
     * VARDATA is a pointer to the data region of the struct.
     */
    memcpy((void *) VARDATA(new_t), /* destination */
           (void *) VARDATA(t),      /* source */
           VARSIZE(t) - VARHDRSZ); /* how many bytes */
    PG_RETURN_TEXT_P(new_t);
}

PG_FUNCTION_INFO_V1(concat_text);

Datum
concat_text(PG_FUNCTION_ARGS)
{
    text *arg1 = PG_GETARG_TEXT_P(0);
    text *arg2 = PG_GETARG_TEXT_P(1);
    int32 new_text_size = VARSIZE(arg1) + VARSIZE(arg2) - VARHDRSZ;
    text *new_text = (text *) palloc(new_text_size);

    SET_VARSIZE(new_text, new_text_size);
    memcpy(VARDATA(new_text), VARDATA(arg1), VARSIZE(arg1) - VARHDRSZ);
    memcpy(VARDATA(new_text) + (VARSIZE(arg1) - VARHDRSZ),
           VARDATA(arg2), VARSIZE(arg2) - VARHDRSZ);
    PG_RETURN_TEXT_P(new_text);
}

```

The `CREATE FUNCTION` commands are the same as for the version-0 equivalents.

At first glance, the version-1 coding conventions might appear to be just pointless obscurantism. They do, however, offer a number of improvements, because the macros can hide unnecessary detail. An example is that in coding `add_one_float8`, we no longer need to be aware that `float8` is a pass-by-reference type. Another example is that the `GETARG` macros for variable-length types allow for more efficient fetching of “toasted” (compressed or out-of-line) values.

One big improvement in version-1 functions is better handling of null inputs and results. The macro `PG_ARGISNULL(n)` allows a function to test whether each input is null. (Of course, doing this is only

necessary in functions not declared “strict”). As with the `PG_GETARG_xxx()` macros, the input arguments are counted beginning at zero. Note that one should refrain from executing `PG_GETARG_xxx()` until one has verified that the argument isn’t null. To return a null result, execute `PG_RETURN_NULL()`; this works in both strict and nonstrict functions.

Other options provided in the new-style interface are two variants of the `PG_GETARG_xxx()` macros. The first of these, `PG_GETARG_xxx_COPY()`, guarantees to return a copy of the specified argument that is safe for writing into. (The normal macros will sometimes return a pointer to a value that is physically stored in a table, which must not be written to. Using the `PG_GETARG_xxx_COPY()` macros guarantees a writable result.) The second variant consists of the `PG_GETARG_xxx_SLICE()` macros which take three arguments. The first is the number of the function argument (as above). The second and third are the offset and length of the segment to be returned. Offsets are counted from zero, and a negative length requests that the remainder of the value be returned. These macros provide more efficient access to parts of large values in the case where they have storage type “external”. (The storage type of a column can be specified using `ALTER TABLE tablename ALTER COLUMN colname SET STORAGE storagetype`. *storagetype* is one of `plain`, `external`, `extended`, or `main`.)

Finally, the version-1 function call conventions make it possible to return set results (Section 34.9.10) and implement trigger functions (Chapter 35) and procedural-language call handlers (Chapter 48). Version-1 code is also more portable than version-0, because it does not break restrictions on function call protocol in the C standard. For more details see `src/backend/utils/fmgr/README` in the source distribution.

### 34.9.5. Writing Code

Before we turn to the more advanced topics, we should discuss some coding rules for PostgreSQL C-language functions. While it might be possible to load functions written in languages other than C into PostgreSQL, this is usually difficult (when it is possible at all) because other languages, such as C++, FORTRAN, or Pascal often do not follow the same calling convention as C. That is, other languages do not pass argument and return values between functions in the same way. For this reason, we will assume that your C-language functions are actually written in C.

The basic rules for writing and building C functions are as follows:

- Use `pg_config --includedir-server` to find out where the PostgreSQL server header files are installed on your system (or the system that your users will be running on).
- Compiling and linking your code so that it can be dynamically loaded into PostgreSQL always requires special flags. See Section 34.9.6 for a detailed explanation of how to do it for your particular operating system.
- Remember to define a “magic block” for your shared library, as described in Section 34.9.1.
- When allocating memory, use the PostgreSQL functions `palloc` and `pfree` instead of the corresponding C library functions `malloc` and `free`. The memory allocated by `palloc` will be freed automatically at the end of each transaction, preventing memory leaks.
- Always zero the bytes of your structures using `memset`. Without this, it’s difficult to support hash indexes or hash joins, as you must pick out only the significant bits of your data structure to compute a hash. Even if you initialize all fields of your structure, there might be alignment padding (holes in the structure) that contain garbage values.

- Most of the internal PostgreSQL types are declared in `postgres.h`, while the function manager interfaces (`PG_FUNCTION_ARGS`, etc.) are in `fmgr.h`, so you will need to include at least these two files. For portability reasons it's best to include `postgres.h` *first*, before any other system or user header files. Including `postgres.h` will also include `elog.h` and `palloc.h` for you.
- Symbol names defined within object files must not conflict with each other or with symbols defined in the PostgreSQL server executable. You will have to rename your functions or variables if you get error messages to this effect.

### 34.9.6. Compiling and Linking Dynamically-Loaded Functions

Before you are able to use your PostgreSQL extension functions written in C, they must be compiled and linked in a special way to produce a file that can be dynamically loaded by the server. To be precise, a *shared library* needs to be created.

For information beyond what is contained in this section you should read the documentation of your operating system, in particular the manual pages for the C compiler, `cc`, and the link editor, `ld`. In addition, the PostgreSQL source code contains several working examples in the `contrib` directory. If you rely on these examples you will make your modules dependent on the availability of the PostgreSQL source code, however.

Creating shared libraries is generally analogous to linking executables: first the source files are compiled into object files, then the object files are linked together. The object files need to be created as *position-independent code* (PIC), which conceptually means that they can be placed at an arbitrary location in memory when they are loaded by the executable. (Object files intended for executables are usually not compiled that way.) The command to link a shared library contains special flags to distinguish it from linking an executable (at least in theory — on some systems the practice is much uglier).

In the following examples we assume that your source code is in a file `foo.c` and we will create a shared library `foo.so`. The intermediate object file will be called `foo.o` unless otherwise noted. A shared library can contain more than one object file, but we only use one here.

#### BSD/OS

The compiler flag to create PIC is `-fpic`. The linker flag to create shared libraries is `-shared`.

```
gcc -fpic -c foo.c
ld -shared -o foo.so foo.o
```

This is applicable as of version 4.0 of BSD/OS.

#### FreeBSD

The compiler flag to create PIC is `-fpic`. To create shared libraries the compiler flag is `-shared`.

```
gcc -fpic -c foo.c
gcc -shared -o foo.so foo.o
```

This is applicable as of version 3.0 of FreeBSD.

**HP-UX**

The compiler flag of the system compiler to create PIC is `+z`. When using GCC it's `-fpic`. The linker flag for shared libraries is `-b`. So:

```
cc +z -c foo.c
```

or:

```
gcc -fpic -c foo.c
```

and then:

```
ld -b -o foo.sl foo.o
```

HP-UX uses the extension `.sl` for shared libraries, unlike most other systems.

**IRIX**

PIC is the default, no special compiler options are necessary. The linker option to produce shared libraries is `-shared`.

```
cc -c foo.c
```

```
ld -shared -o foo.so foo.o
```

**Linux**

The compiler flag to create PIC is `-fpic`. On some platforms in some situations `-fPIC` must be used if `-fpic` does not work. Refer to the GCC manual for more information. The compiler flag to create a shared library is `-shared`. A complete example looks like this:

```
cc -fpic -c foo.c
```

```
cc -shared -o foo.so foo.o
```

**MacOS X**

Here is an example. It assumes the developer tools are installed.

```
cc -c foo.c
```

```
cc -bundle -flat_namespace -undefined suppress -o foo.so foo.o
```

**NetBSD**

The compiler flag to create PIC is `-fpic`. For ELF systems, the compiler with the flag `-shared` is used to link shared libraries. On the older non-ELF systems, `ld -Bshareable` is used.

```
gcc -fpic -c foo.c
```

```
gcc -shared -o foo.so foo.o
```

**OpenBSD**

The compiler flag to create PIC is `-fpic`. `ld -Bshareable` is used to link shared libraries.

```
gcc -fpic -c foo.c
```

```
ld -Bshareable -o foo.so foo.o
```

**Solaris**

The compiler flag to create PIC is `-KPIC` with the Sun compiler and `-fpic` with GCC. To link shared libraries, the compiler option is `-G` with either compiler or alternatively `-shared` with GCC.

```
cc -KPIC -c foo.c
```

```
cc -G -o foo.so foo.o
```

or

```
gcc -fpic -c foo.c
```

```
gcc -G -o foo.so foo.o
```

### Tru64 UNIX

PIC is the default, so the compilation command is the usual one. `ld` with special options is used to do the linking.

```
cc -c foo.c
ld -shared -expect_unresolved '*' -o foo.so foo.o
```

The same procedure is used with GCC instead of the system compiler; no special options are required.

### UnixWare

The compiler flag to create PIC is `-K PIC` with the SCO compiler and `-fpic` with GCC. To link shared libraries, the compiler option is `-G` with the SCO compiler and `-shared` with GCC.

```
cc -K PIC -c foo.c
cc -G -o foo.so foo.o
or
gcc -fpic -c foo.c
gcc -shared -o foo.so foo.o
```

**Tip:** If this is too complicated for you, you should consider using GNU Libtool<sup>1</sup>, which hides the platform differences behind a uniform interface.

The resulting shared library file can then be loaded into PostgreSQL. When specifying the file name to the `CREATE FUNCTION` command, one must give it the name of the shared library file, not the intermediate object file. Note that the system's standard shared-library extension (usually `.so` or `.sl`) can be omitted from the `CREATE FUNCTION` command, and normally should be omitted for best portability.

Refer back to Section 34.9.1 about where the server expects to find the shared library files.

## 34.9.7. Extension Building Infrastructure

If you are thinking about distributing your PostgreSQL extension modules, setting up a portable build system for them can be fairly difficult. Therefore the PostgreSQL installation provides a build infrastructure for extensions, called PGXS, so that simple extension modules can be built simply against an already installed server. Note that this infrastructure is not intended to be a universal build system framework that can be used to build all software interfacing to PostgreSQL; it simply automates common build rules for simple server extension modules. For more complicated packages, you need to write your own build system.

To use the infrastructure for your extension, you must write a simple makefile. In that makefile, you need to set some variables and finally include the global PGXS makefile. Here is an example that builds an extension module named `isbn_issn` consisting of a shared library, an SQL script, and a documentation text file:

```
MODULES = isbn_issn
DATA_built = isbn_issn.sql
DOCS = README.isbn_issn
```

1. <http://www.gnu.org/software/libtool/>

```
PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

The last three lines should always be the same. Earlier in the file, you assign variables or add custom make rules.

The following variables can be set:

MODULES

list of shared objects to be built from source file with same stem (do not include suffix in this list)

DATA

random files to install into *prefix*/share/contrib

DATA\_built

random files to install into *prefix*/share/contrib, which need to be built first

DOCS

random files to install under *prefix*/doc/contrib

SCRIPTS

script files (not binaries) to install into *prefix*/bin

SCRIPTS\_built

script files (not binaries) to install into *prefix*/bin, which need to be built first

REGRESS

list of regression test cases (without suffix), see below

or at most one of these two:

PROGRAM

a binary program to build (list objects files in OBJS)

MODULE\_big

a shared object to build (list object files in OBJS)

The following can also be set:

EXTRA\_CLEAN

extra files to remove in `make clean`

PG\_CPPFLAGS

will be added to CPPFLAGS

PG\_LIBS

will be added to PROGRAM link line

SHLIB\_LINK

will be added to MODULE\_big link line

`PG_CONFIG`

path to `pg_config` program for the PostgreSQL installation to build against (typically just `pg_config` to use the first one in your `PATH`)

Put this makefile as `Makefile` in the directory which holds your extension. Then you can do `make` to compile, and later `make install` to install your module. By default, the extension is compiled and installed for the PostgreSQL installation that corresponds to the first `pg_config` program found in your path. You can use a different installation by setting `PG_CONFIG` to point to its `pg_config` program, either within the makefile or on the `make` command line.

### Caution

Changing `PG_CONFIG` only works when building against PostgreSQL 8.3 or later. With older releases it does not work to set it to anything except `pg_config`; you must alter your `PATH` to select the installation to build against.

The scripts listed in the `REGRESS` variable are used for regression testing of your module, just like `make installcheck` is used for the main PostgreSQL server. For this to work you need to have a subdirectory named `sql/` in your extension's directory, within which you put one file for each group of tests you want to run. The files should have extension `.sql`, which should not be included in the `REGRESS` list in the makefile. For each test there should be a file containing the expected result in a subdirectory named `expected/`, with extension `.out`. The tests are run by executing `make installcheck`, and the resulting output will be compared to the expected files. The differences will be written to the file `regression.diffs` in `diff -c` format. Note that trying to run a test which is missing the expected file will be reported as "trouble", so make sure you have all expected files.

**Tip:** The easiest way of creating the expected files is creating empty files, then carefully inspecting the result files after a test run (to be found in the `results/` directory), and copying them to `expected/` if they match what you want from the test.

## 34.9.8. Composite-Type Arguments

Composite types do not have a fixed layout like C structures. Instances of a composite type can contain null fields. In addition, composite types that are part of an inheritance hierarchy can have different fields than other members of the same inheritance hierarchy. Therefore, PostgreSQL provides a function interface for accessing fields of composite types from C.

Suppose we want to write a function to answer the query:

```
SELECT name, c_overpaid(emp, 1500) AS overpaid
FROM emp
WHERE name = 'Bill' OR name = 'Sam';
```

Using call conventions version 0, we can define `c_overpaid` as:

```
#include "postgres.h"
```

```

#include "executor/executor.h" /* for GetAttributeByName() */

bool
c_overpaid(HeapTupleHeader t, /* the current row of emp */
           int32 limit)
{
    bool isnull;
    int32 salary;

    salary = DatumGetInt32(GetAttributeByName(t, "salary", &isnull));
    if (isnull)
        return false;
    return salary > limit;
}

```

In version-1 coding, the above would look like this:

```

#include "postgres.h"
#include "executor/executor.h" /* for GetAttributeByName() */

PG_FUNCTION_INFO_V1(c_overpaid);

Datum
c_overpaid(PG_FUNCTION_ARGS)
{
    HeapTupleHeader t = PG_GETARG_HEAPTUPLEHEADER(0);
    int32          limit = PG_GETARG_INT32(1);
    bool isnull;
    Datum salary;

    salary = GetAttributeByName(t, "salary", &isnull);
    if (isnull)
        PG_RETURN_BOOL(false);
    /* Alternatively, we might prefer to do PG_RETURN_NULL() for null salary. */

    PG_RETURN_BOOL(DatumGetInt32(salary) > limit);
}

```

`GetAttributeByName` is the PostgreSQL system function that returns attributes out of the specified row. It has three arguments: the argument of type `HeapTupleHeader` passed into the function, the name of the desired attribute, and a return parameter that tells whether the attribute is null. `GetAttributeByName` returns a `Datum` value that you can convert to the proper data type by using the appropriate `DatumGetXXX()` macro. Note that the return value is meaningless if the null flag is set; always check the null flag before trying to do anything with the result.

There is also `GetAttributeByNum`, which selects the target attribute by column number instead of name.

The following command declares the function `c_overpaid` in SQL:

```

CREATE FUNCTION c_overpaid(emp, integer) RETURNS boolean
AS 'DIRECTORY/funcs', 'c_overpaid'
LANGUAGE C STRICT;

```

Notice we have used `STRICT` so that we did not have to check whether the input arguments were `NULL`.

### 34.9.9. Returning Rows (Composite Types)

To return a row or composite-type value from a C-language function, you can use a special API that provides macros and functions to hide most of the complexity of building composite data types. To use this API, the source file must include:

```
#include "funcapi.h"
```

There are two ways you can build a composite data value (henceforth a “tuple”): you can build it from an array of `Datum` values, or from an array of C strings that can be passed to the input conversion functions of the tuple’s column data types. In either case, you first need to obtain or construct a `TupleDesc` descriptor for the tuple structure. When working with `Datums`, you pass the `TupleDesc` to `BlessTupleDesc`, and then call `heap_form_tuple` for each row. When working with C strings, you pass the `TupleDesc` to `TupleDescGetAttInMetadata`, and then call `BuildTupleFromCStrings` for each row. In the case of a function returning a set of tuples, the setup steps can all be done once during the first call of the function.

Several helper functions are available for setting up the needed `TupleDesc`. The recommended way to do this in most functions returning composite values is to call:

```
TypeFuncClass get_call_result_type(FunctionCallInfo fcinfo,
                                   Oid *resultTypeId,
                                   TupleDesc *resultTupleDesc)
```

passing the same `fcinfo` struct passed to the calling function itself. (This of course requires that you use the version-1 calling conventions.) `resultTypeId` can be specified as `NULL` or as the address of a local variable to receive the function’s result type OID. `resultTupleDesc` should be the address of a local `TupleDesc` variable. Check that the result is `TYPEFUNC_COMPOSITE`; if so, `resultTupleDesc` has been filled with the needed `TupleDesc`. (If it is not, you can report an error along the lines of “function returning record called in context that cannot accept type record”.)

**Tip:** `get_call_result_type` can resolve the actual type of a polymorphic function result; so it is useful in functions that return scalar polymorphic results, not only functions that return composites. The `resultTypeId` output is primarily useful for functions returning polymorphic scalars.

**Note:** `get_call_result_type` has a sibling `get_expr_result_type`, which can be used to resolve the expected output type for a function call represented by an expression tree. This can be used when trying to determine the result type from outside the function itself. There is also `get_func_result_type`, which can be used when only the function’s OID is available. However these functions are not able to deal with functions declared to return `record`, and `get_func_result_type` cannot resolve polymorphic types, so you should preferentially use `get_call_result_type`.

Older, now-deprecated functions for obtaining `TupleDescs` are:

```
TupleDesc RelationNameGetTupleDesc(const char *relname)
```

to get a `TupleDesc` for the row type of a named relation, and:

```
TupleDesc TypeGetTupleDesc(Oid typeoid, List *colaliases)
```

to get a `TupleDesc` based on a type OID. This can be used to get a `TupleDesc` for a base or composite type. It will not work for a function that returns `record`, however, and it cannot resolve polymorphic types.

Once you have a `TupleDesc`, call:

```
TupleDesc BlessTupleDesc(TupleDesc tupdesc)
```

if you plan to work with `Datums`, or:

```
AttInMetadata *TupleDescGetAttInMetadata(TupleDesc tupdesc)
```

if you plan to work with C strings. If you are writing a function returning set, you can save the results of these functions in the `FuncCallContext` structure — use the `tuple_desc` or `attinmeta` field respectively.

When working with `Datums`, use:

```
HeapTuple heap_form_tuple(TupleDesc tupdesc, Datum *values, bool *isnull)
```

to build a `HeapTuple` given user data in `Datum` form.

When working with C strings, use:

```
HeapTuple BuildTupleFromCStrings(AttInMetadata *attinmeta, char **values)
```

to build a `HeapTuple` given user data in C string form. `values` is an array of C strings, one for each attribute of the return row. Each C string should be in the form expected by the input function of the attribute data type. In order to return a null value for one of the attributes, the corresponding pointer in the `values` array should be set to `NULL`. This function will need to be called again for each row you return.

Once you have built a tuple to return from your function, it must be converted into a `Datum`. Use:

```
HeapTupleGetDatum(HeapTuple tuple)
```

to convert a `HeapTuple` into a valid `Datum`. This `Datum` can be returned directly if you intend to return just a single row, or it can be used as the current return value in a set-returning function.

An example appears in the next section.

### 34.9.10. Returning Sets

There is also a special API that provides support for returning sets (multiple rows) from a C-language function. A set-returning function must follow the version-1 calling conventions. Also, source files must include `funcapi.h`, as above.

A set-returning function (SRF) is called once for each item it returns. The SRF must therefore save enough state to remember what it was doing and return the next item on each call. The

structure `FuncCallContext` is provided to help control this process. Within a function, `fcinfo->flinfo->fn_extra` is used to hold a pointer to `FuncCallContext` across calls.

```
typedef struct
{
    /*
     * Number of times we've been called before
     */
    /* call_cntr is initialized to 0 for you by SRF_FIRSTCALL_INIT(), and
     * incremented for you every time SRF_RETURN_NEXT() is called.
     */
    uint32 call_cntr;

    /*
     * OPTIONAL maximum number of calls
     */
    /* max_calls is here for convenience only and setting it is optional.
     * If not set, you must provide alternative means to know when the
     * function is done.
     */
    uint32 max_calls;

    /*
     * OPTIONAL pointer to result slot
     */
    /* This is obsolete and only present for backwards compatibility, viz,
     * user-defined SRFs that use the deprecated TupleDescGetSlot().
     */
    TupleTableSlot *slot;

    /*
     * OPTIONAL pointer to miscellaneous user-provided context information
     */
    /* user_fctx is for use as a pointer to your own data to retain
     * arbitrary context information between calls of your function.
     */
    void *user_fctx;

    /*
     * OPTIONAL pointer to struct containing attribute type input metadata
     */
    /* attinmeta is for use when returning tuples (i.e., composite data types)
     * and is not used when returning base data types. It is only needed
     * if you intend to use BuildTupleFromCStrings() to create the return
     * tuple.
     */
    AttInMetadata *attinmeta;

    /*
     * memory context used for structures that must live for multiple calls
     */
    /* multi_call_memory_ctx is set by SRF_FIRSTCALL_INIT() for you, and used
     * by SRF_RETURN_DONE() for cleanup. It is the most appropriate memory
```

```

    * context for any memory that is to be reused across multiple calls
    * of the SRF.
    */
    MemoryContext multi_call_memory_ctx;

    /*
     * OPTIONAL pointer to struct containing tuple description
     *
     * tuple_desc is for use when returning tuples (i.e. composite data types)
     * and is only needed if you are going to build the tuples with
     * heap_form_tuple() rather than with BuildTupleFromCStrings(). Note that
     * the TupleDesc pointer stored here should usually have been run through
     * BlessTupleDesc() first.
     */
    TupleDesc tuple_desc;
} FuncCallContext;

```

An SRF uses several functions and macros that automatically manipulate the `FuncCallContext` structure (and expect to find it via `fn_extra`). Use:

```
SRF_IS_FIRSTCALL()
```

to determine if your function is being called for the first or a subsequent time. On the first call (only) use:

```
SRF_FIRSTCALL_INIT()
```

to initialize the `FuncCallContext`. On every function call, including the first, use:

```
SRF_PERCALL_SETUP()
```

to properly set up for using the `FuncCallContext` and clearing any previously returned data left over from the previous pass.

If your function has data to return, use:

```
SRF_RETURN_NEXT(funcctx, result)
```

to return it to the caller. (`result` must be of type `Datum`, either a single value or a tuple prepared as described above.) Finally, when your function is finished returning data, use:

```
SRF_RETURN_DONE(funcctx)
```

to clean up and end the SRF.

The memory context that is current when the SRF is called is a transient context that will be cleared between calls. This means that you do not need to call `pfree` on everything you allocated using `palloc`; it will go away anyway. However, if you want to allocate any data structures to live across calls, you need to put them somewhere else. The memory context referenced by `multi_call_memory_ctx` is a suitable location for any data that needs to survive until the SRF is finished running. In most cases, this means that you should switch into `multi_call_memory_ctx` while doing the first-call setup.

A complete pseudo-code example looks like the following:

```

Datum
my_set_returning_function(PG_FUNCTION_ARGS)
{
    FuncCallContext    *funcctx;
    Datum               result;
    MemoryContext        oldcontext;
    further declarations as needed

    if (SRF_IS_FIRSTCALL())
    {
        funcctx = SRF_FIRSTCALL_INIT();
        oldcontext = MemoryContextSwitchTo(funcctx->multi_call_memory_ctx);
        /* One-time setup code appears here: */
        user code
        if returning composite
            build TupleDesc, and perhaps AttInMetadata
        endif returning composite
        user code
        MemoryContextSwitchTo(oldcontext);
    }

    /* Each-time setup code appears here: */
    user code
    funcctx = SRF_PERCALL_SETUP();
    user code

    /* this is just one way we might test whether we are done: */
    if (funcctx->call_cntr < funcctx->max_calls)
    {
        /* Here we want to return another item: */
        user code
        obtain result Datum
        SRF_RETURN_NEXT(funcctx, result);
    }
    else
    {
        /* Here we are done returning items and just need to clean up: */
        user code
        SRF_RETURN_DONE(funcctx);
    }
}

```

A complete example of a simple SRF returning a composite type looks like:

```

PG_FUNCTION_INFO_V1(retcomposite);

Datum
retcomposite(PG_FUNCTION_ARGS)
{
    FuncCallContext    *funcctx;
    int                 call_cntr;
    int                 max_calls;

```

```

TupleDesc          tupdesc;
AttInMetadata      *attinmeta;

/* stuff done only on the first call of the function */
if (SRF_IS_FIRSTCALL())
{
    MemoryContext    oldcontext;

    /* create a function context for cross-call persistence */
    funcctx = SRF_FIRSTCALL_INIT();

    /* switch to memory context appropriate for multiple function calls */
    oldcontext = MemoryContextSwitchTo(funcctx->multi_call_memory_ctx);

    /* total number of tuples to be returned */
    funcctx->max_calls = PG_GETARG_UINT32(0);

    /* Build a tuple descriptor for our result type */
    if (get_call_result_type(fcinfo, NULL, &tupdesc) != TYPEFUNC_COMPOSITE)
        ereport(ERROR,
                (errcode(ERRCODE_FEATURE_NOT_SUPPORTED),
                 errmsg("function returning record called in context "
                        "that cannot accept type record")));

    /*
     * generate attribute metadata needed later to produce tuples from raw
     * C strings
     */
    attinmeta = TupleDescGetAttInMetadata(tupdesc);
    funcctx->attinmeta = attinmeta;

    MemoryContextSwitchTo(oldcontext);
}

/* stuff done on every call of the function */
funcctx = SRF_PERCALL_SETUP();

call_cntr = funcctx->call_cntr;
max_calls = funcctx->max_calls;
attinmeta = funcctx->attinmeta;

if (call_cntr < max_calls)    /* do when there is more left to send */
{
    char          **values;
    HeapTuple      tuple;
    Datum          result;

    /*
     * Prepare a values array for building the returned tuple.
     * This should be an array of C strings which will
     * be processed later by the type input functions.
     */
    values = (char **) palloc(3 * sizeof(char *));

```

```

values[0] = (char *) palloc(16 * sizeof(char));
values[1] = (char *) palloc(16 * sizeof(char));
values[2] = (char *) palloc(16 * sizeof(char));

snprintf(values[0], 16, "%d", 1 * PG_GETARG_INT32(1));
snprintf(values[1], 16, "%d", 2 * PG_GETARG_INT32(1));
snprintf(values[2], 16, "%d", 3 * PG_GETARG_INT32(1));

/* build a tuple */
tuple = BuildTupleFromCStrings(attinmeta, values);

/* make the tuple into a datum */
result = HeapTupleGetDatum(tuple);

/* clean up (this is not really necessary) */
pfree(values[0]);
pfree(values[1]);
pfree(values[2]);
pfree(values);

SRF_RETURN_NEXT(funcctx, result);
}
else /* do when there is no more left */
{
    SRF_RETURN_DONE(funcctx);
}
}

```

One way to declare this function in SQL is:

```

CREATE TYPE __retcomposite AS (f1 integer, f2 integer, f3 integer);

CREATE OR REPLACE FUNCTION retcomposite(integer, integer)
    RETURNS SETOF __retcomposite
    AS 'filename', 'retcomposite'
    LANGUAGE C IMMUTABLE STRICT;

```

A different way is to use OUT parameters:

```

CREATE OR REPLACE FUNCTION retcomposite(IN integer, IN integer,
    OUT f1 integer, OUT f2 integer, OUT f3 integer)
    RETURNS SETOF record
    AS 'filename', 'retcomposite'
    LANGUAGE C IMMUTABLE STRICT;

```

Notice that in this method the output type of the function is formally an anonymous `record` type.

The directory `contrib/tablefunc` in the source distribution contains more examples of set-returning functions.

### 34.9.11. Polymorphic Arguments and Return Types

C-language functions can be declared to accept and return the polymorphic types `anyelement`, `anyarray`, `anynonarray`, and `anyenum`. See Section 34.2.5 for a more detailed explanation of polymorphic functions. When function arguments or return types are defined as polymorphic types, the function author cannot know in advance what data type it will be called with, or need to return. There are two routines provided in `fmgr.h` to allow a version-1 C function to discover the actual data types of its arguments and the type it is expected to return. The routines are called `get_fn_expr_rettype(FmgrInfo *flinfo)` and `get_fn_expr_argtype(FmgrInfo *flinfo, int argnum)`. They return the result or argument type OID, or `InvalidOid` if the information is not available. The structure `flinfo` is normally accessed as `fcinfo->flinfo`. The parameter `argnum` is zero based. `get_call_result_type` can also be used as an alternative to `get_fn_expr_rettype`.

For example, suppose we want to write a function to accept a single element of any type, and return a one-dimensional array of that type:

```
PG_FUNCTION_INFO_V1(make_array);
Datum
make_array(PG_FUNCTION_ARGS)
{
    ArrayType *result;
    Oid        element_type = get_fn_expr_argtype(fcinfo->flinfo, 0);
    Datum      element;
    bool       isnull;
    int16      typelen;
    bool       typbyval;
    char       typalign;
    int        ndims;
    int        dims[MAXDIM];
    int        lbs[MAXDIM];

    if (!OidIsValid(element_type))
        elog(ERROR, "could not determine data type of input");

    /* get the provided element, being careful in case it's NULL */
    isnull = PG_ARGISNULL(0);
    if (isnull)
        element = (Datum) 0;
    else
        element = PG_GETARG_DATUM(0);

    /* we have one dimension */
    ndims = 1;
    /* and one element */
    dims[0] = 1;
    /* and lower bound is 1 */
    lbs[0] = 1;

    /* get required info about the element type */
    get_typlenbyvalalign(element_type, &typelen, &typbyval, &typalign);

    /* now build the array */
    result = construct_md_array(&element, &isnull, ndims, dims, lbs,
```

```

        element_type, typlen, typbyval, tyalign);

    PG_RETURN_ARRAYTYPE_P(result);
}

```

The following command declares the function `make_array` in SQL:

```

CREATE FUNCTION make_array(anyelement) RETURNS anyarray
AS 'DIRECTORY/funcs', 'make_array'
LANGUAGE C IMMUTABLE;

```

### 34.9.12. Shared Memory and LWLocks

Add-ins can reserve LWLocks and an allocation of shared memory on server startup. The add-in's shared library must be preloaded by specifying it in `shared_preload_libraries`. Shared memory is reserved by calling:

```
void RequestAddinShmemSpace(int size)
```

from your `_PG_init` function.

LWLocks are reserved by calling:

```
void RequestAddinLWLocks(int n)
```

from `_PG_init`.

To avoid possible race-conditions, each backend should use the LWLock `AddinShmemInitLock` when connecting to and initializing its allocation of shared memory, as shown here:

```

static mystruct *ptr = NULL;

if (!ptr)
{
    bool    found;

    LWLockAcquire(AddinShmemInitLock, LW_EXCLUSIVE);
    ptr = ShmemInitStruct("my struct name", size, &found);
    if (!ptr)
        elog(ERROR, "out of shared memory");
    if (!found)
    {
        initialize contents of shmem area;
        acquire any requested LWLocks using:
        ptr->mylockid = LWLockAssign();
    }
    LWLockRelease(AddinShmemInitLock);
}

```

## 34.10. User-Defined Aggregates

Aggregate functions in PostgreSQL are expressed in terms of *state values* and *state transition functions*. That is, an aggregate operates using a state value that is updated as each successive input row is processed. To define a new aggregate function, one selects a data type for the state value, an initial value for the state, and a state transition function. The state transition function is just an ordinary function that could also be used outside the context of the aggregate. A *final function* can also be specified, in case the desired result of the aggregate is different from the data that needs to be kept in the running state value.

Thus, in addition to the argument and result data types seen by a user of the aggregate, there is an internal state-value data type that might be different from both the argument and result types.

If we define an aggregate that does not use a final function, we have an aggregate that computes a running function of the column values from each row. `sum` is an example of this kind of aggregate. `sum` starts at zero and always adds the current row's value to its running total. For example, if we want to make a `sum` aggregate to work on a data type for complex numbers, we only need the addition function for that data type. The aggregate definition would be:

```
CREATE AGGREGATE sum (complex)
(
    sfunc = complex_add,
    stype = complex,
    initcond = ' (0,0) '
);

SELECT sum(a) FROM test_complex;

      sum
-----
(34,53.9)
```

(Notice that we are relying on function overloading: there is more than one aggregate named `sum`, but PostgreSQL can figure out which kind of `sum` applies to a column of type `complex`.)

The above definition of `sum` will return zero (the initial state condition) if there are no nonnull input values. Perhaps we want to return null in that case instead — the SQL standard expects `sum` to behave that way. We can do this simply by omitting the `initcond` phrase, so that the initial state condition is null. Ordinarily this would mean that the `sfunc` would need to check for a null state-condition input, but for `sum` and some other simple aggregates like `max` and `min`, it is sufficient to insert the first nonnull input value into the state variable and then start applying the transition function at the second nonnull input value. PostgreSQL will do that automatically if the initial condition is null and the transition function is marked “strict” (i.e., not to be called for null inputs).

Another bit of default behavior for a “strict” transition function is that the previous state value is retained unchanged whenever a null input value is encountered. Thus, null values are ignored. If you need some other behavior for null inputs, do not declare your transition function as strict; instead code it to test for null inputs and do whatever is needed.

`avg` (average) is a more complex example of an aggregate. It requires two pieces of running state: the sum of the inputs and the count of the number of inputs. The final result is obtained by dividing these quantities. Average is typically implemented by using a two-element array as the state value. For example, the built-in implementation of `avg(float8)` looks like:

```
CREATE AGGREGATE avg (float8)
(
    sfunc = float8_accum,
    stype = float8[],
    finalfunc = float8_avg,
    initcond = '{0,0}'
);
```

Aggregate functions can use polymorphic state transition functions or final functions, so that the same functions can be used to implement multiple aggregates. See Section 34.2.5 for an explanation of polymorphic functions. Going a step further, the aggregate function itself can be specified with polymorphic input type(s) and state type, allowing a single aggregate definition to serve for multiple input data types. Here is an example of a polymorphic aggregate:

```
CREATE AGGREGATE array_accum (anyelement)
(
    sfunc = array_append,
    stype = anyarray,
    initcond = '{}'
);
```

Here, the actual state type for any aggregate call is the array type having the actual input type as elements.

Here's the output using two different actual data types as arguments:

```
SELECT attrelid::regclass, array_accum(attname)
FROM pg_attribute
WHERE attnum > 0 AND attrelid = 'pg_tablespace'::regclass
GROUP BY attrelid;
```

```
attrelid | array_accum
-----+-----
pg_tablespace | {spcname,spcowner,spclocation,spcACL}
(1 row)
```

```
SELECT attrelid::regclass, array_accum(atttypid)
FROM pg_attribute
WHERE attnum > 0 AND attrelid = 'pg_tablespace'::regclass
GROUP BY attrelid;
```

```
attrelid | array_accum
-----+-----
pg_tablespace | {19,26,25,1034}
(1 row)
```

A function written in C can detect that it is being called as an aggregate transition or final function by seeing if it was passed an `AggState` node as the function call “context”, for example by:

```
if (fcinfo->context && IsA(fcinfo->context, AggState))
```

One reason for checking this is that when it is true, the first input must be a temporary transition value and can therefore safely be modified in-place rather than allocating a new copy. (This is the *only* case where it is safe for a function to modify a pass-by-reference input.) See `int8inc()` for an example.

For further details see the `CREATE AGGREGATE` command.

## 34.11. User-Defined Types

As described in Section 34.2, PostgreSQL can be extended to support new data types. This section describes how to define new base types, which are data types defined below the level of the SQL language. Creating a new base type requires implementing functions to operate on the type in a low-level language, usually C.

The examples in this section can be found in `complex.sql` and `complex.c` in the `src/tutorial` directory of the source distribution. See the `README` file in that directory for instructions about running the examples.

A user-defined type must always have input and output functions. These functions determine how the type appears in strings (for input by the user and output to the user) and how the type is organized in memory. The input function takes a null-terminated character string as its argument and returns the internal (in memory) representation of the type. The output function takes the internal representation of the type as argument and returns a null-terminated character string. If we want to do anything more with the type than merely store it, we must provide additional functions to implement whatever operations we’d like to have for the type.

Suppose we want to define a type `complex` that represents complex numbers. A natural way to represent a complex number in memory would be the following C structure:

```
typedef struct Complex {
    double    x;
    double    y;
} Complex;
```

We will need to make this a pass-by-reference type, since it’s too large to fit into a single `Datum` value.

As the external string representation of the type, we choose a string of the form `(x,y)`.

The input and output functions are usually not hard to write, especially the output function. But when defining the external string representation of the type, remember that you must eventually write a complete and robust parser for that representation as your input function. For instance:

```
PG_FUNCTION_INFO_V1(complex_in);

Datum
complex_in(PG_FUNCTION_ARGS)
{
    char        *str = PG_GETARG_CSTRING(0);
```

```

double      x,
            y;
Complex     *result;

if (sscanf(str, " ( %lf , %lf )", &x, &y) != 2)
    ereport(ERROR,
              (errcode(ERRCODE_INVALID_TEXT_REPRESENTATION),
               errmsg("invalid input syntax for complex: \"%s\"",
                      str)));

result = (Complex *) palloc(sizeof(Complex));
result->x = x;
result->y = y;
PG_RETURN_POINTER(result);
}

```

The output function can simply be:

```

PG_FUNCTION_INFO_V1(complex_out);

Datum
complex_out(PG_FUNCTION_ARGS)
{
    Complex    *complex = (Complex *) PG_GETARG_POINTER(0);
    char        *result;

    result = (char *) palloc(100);
    snprintf(result, 100, "(%g,%g)", complex->x, complex->y);
    PG_RETURN_CSTRING(result);
}

```

You should be careful to make the input and output functions inverses of each other. If you do not, you will have severe problems when you need to dump your data into a file and then read it back in. This is a particularly common problem when floating-point numbers are involved.

Optionally, a user-defined type can provide binary input and output routines. Binary I/O is normally faster but less portable than textual I/O. As with textual I/O, it is up to you to define exactly what the external binary representation is. Most of the built-in data types try to provide a machine-independent binary representation. For `complex`, we will piggy-back on the binary I/O converters for type `float8`:

```

PG_FUNCTION_INFO_V1(complex_recv);

Datum
complex_recv(PG_FUNCTION_ARGS)
{
    StringInfo  buf = (StringInfo) PG_GETARG_POINTER(0);
    Complex     *result;

    result = (Complex *) palloc(sizeof(Complex));
    result->x = pq_getmsgfloat8(buf);
    result->y = pq_getmsgfloat8(buf);
    PG_RETURN_POINTER(result);
}

```

```

}

PG_FUNCTION_INFO_V1 (complex_send);

Datum
complex_send(PG_FUNCTION_ARGS)
{
    Complex    *complex = (Complex *) PG_GETARG_POINTER(0);
    StringInfoData buf;

    pq_begintypsend(&buf);
    pq_sendfloat8(&buf, complex->x);
    pq_sendfloat8(&buf, complex->y);
    PG_RETURN_BYTEA_P(pq_endtypsend(&buf));
}

```

Once we have written the I/O functions and compiled them into a shared library, we can define the `complex` type in SQL. First we declare it as a shell type:

```
CREATE TYPE complex;
```

This serves as a placeholder that allows us to reference the type while defining its I/O functions. Now we can define the I/O functions:

```

CREATE FUNCTION complex_in(cstring)
    RETURNS complex
    AS 'filename'
    LANGUAGE C IMMUTABLE STRICT;

CREATE FUNCTION complex_out(complex)
    RETURNS cstring
    AS 'filename'
    LANGUAGE C IMMUTABLE STRICT;

CREATE FUNCTION complex_recv(internal)
    RETURNS complex
    AS 'filename'
    LANGUAGE C IMMUTABLE STRICT;

CREATE FUNCTION complex_send(complex)
    RETURNS bytea
    AS 'filename'
    LANGUAGE C IMMUTABLE STRICT;

```

Finally, we can provide the full definition of the data type:

```

CREATE TYPE complex (
    internallength = 16,
    input = complex_in,
    output = complex_out,

```

```

    receive = complex_recv,
    send = complex_send,
    alignment = double
);

```

When you define a new base type, PostgreSQL automatically provides support for arrays of that type. The array type typically has the same name as the base type with the underscore character (`_`) prepended.

Once the data type exists, we can declare additional functions to provide useful operations on the data type. Operators can then be defined atop the functions, and if needed, operator classes can be created to support indexing of the data type. These additional layers are discussed in following sections.

If the values of your data type vary in size (in internal form), you should make the data type TOAST-able (see Section 53.2). You should do this even if the data are always too small to be compressed or stored externally, because TOAST can save space on small data too, by reducing header overhead.

To do this, the internal representation must follow the standard layout for variable-length data: the first four bytes must be a `char[4]` field which is never accessed directly (customarily named `vl_len_`). You must use `SET_VARSIZE()` to store the size of the datum in this field and `VARSIZE()` to retrieve it. The C functions operating on the data type must always be careful to unpack any toasted values they are handed, by using `PG_DETOAST_DATUM`. (This detail is customarily hidden by defining type-specific `GETARG_DATATYPE_P` macros.) Then, when running the `CREATE TYPE` command, specify the internal length as `variable` and select the appropriate storage option.

If the alignment is unimportant (either just for a specific function or because the data type specifies byte alignment anyways) then it's possible to avoid some of the overhead of `PG_DETOAST_DATUM`. You can use `PG_DETOAST_DATUM_PACKED` instead (customarily hidden by defining a `GETARG_DATATYPE_PP` macro) and using the macros `VARSIZE_ANY_EXHDR` and `VARDATA_ANY` to access a potentially-packed datum. Again, the data returned by these macros is not aligned even if the data type definition specifies an alignment. If the alignment is important you must go through the regular `PG_DETOAST_DATUM` interface.

**Note:** Older code frequently declares `vl_len_` as an `int32` field instead of `char[4]`. This is OK as long as the struct definition has other fields that have at least `int32` alignment. But it is dangerous to use such a struct definition when working with a potentially unaligned datum; the compiler may take it as license to assume the datum actually is aligned, leading to core dumps on architectures that are strict about alignment.

For further details see the description of the `CREATE TYPE` command.

## 34.12. User-Defined Operators

Every operator is “syntactic sugar” for a call to an underlying function that does the real work; so you must first create the underlying function before you can create the operator. However, an operator is *not merely* syntactic sugar, because it carries additional information that helps the query planner optimize queries that use the operator. The next section will be devoted to explaining that additional information.

PostgreSQL supports left unary, right unary, and binary operators. Operators can be overloaded; that is, the same operator name can be used for different operators that have different numbers and types of operands.

When a query is executed, the system determines the operator to call from the number and types of the provided operands.

Here is an example of creating an operator for adding two complex numbers. We assume we've already created the definition of type `complex` (see Section 34.11). First we need a function that does the work, then we can define the operator:

```
CREATE FUNCTION complex_add(complex, complex)
    RETURNS complex
    AS 'filename', 'complex_add'
    LANGUAGE C IMMUTABLE STRICT;

CREATE OPERATOR + (
    leftarg = complex,
    rightarg = complex,
    procedure = complex_add,
    commutator = +
);
```

Now we could execute a query like this:

```
SELECT (a + b) AS c FROM test_complex;
```

```

      c
-----
(5.2,6.05)
(133.42,144.95)
```

We've shown how to create a binary operator here. To create unary operators, just omit one of `leftarg` (for left unary) or `rightarg` (for right unary). The `procedure` clause and the argument clauses are the only required items in `CREATE OPERATOR`. The `commutator` clause shown in the example is an optional hint to the query optimizer. Further details about `commutator` and other optimizer hints appear in the next section.

## 34.13. Operator Optimization Information

A PostgreSQL operator definition can include several optional clauses that tell the system useful things about how the operator behaves. These clauses should be provided whenever appropriate, because they can make for considerable speedups in execution of queries that use the operator. But if you provide them, you must be sure that they are right! Incorrect use of an optimization clause can result in slow queries, subtly wrong output, or other Bad Things. You can always leave out an optimization clause if you are not sure about it; the only consequence is that queries might run slower than they need to.

Additional optimization clauses might be added in future versions of PostgreSQL. The ones described here are all the ones that release 8.3.1 understands.

### 34.13.1. COMMUTATOR

The `COMMUTATOR` clause, if provided, names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if  $(x \text{ A } y)$  equals  $(y \text{ B } x)$  for all possible input values  $x, y$ . Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others' commutators, and operator `+` is usually commutative with itself. But operator `-` is usually not commutative with anything.

The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that PostgreSQL needs to be given to look up the commutator, and that's all that needs to be provided in the `COMMUTATOR` clause.

It's critical to provide commutator information for operators that will be used in indexes and join clauses, because this allows the query optimizer to "flip around" such a clause to the forms needed for different plan types. For example, consider a query with a `WHERE` clause like `tab1.x = tab2.y`, where `tab1.x` and `tab2.y` are of a user-defined type, and suppose that `tab2.y` is indexed. The optimizer cannot generate an index scan unless it can determine how to flip the clause around to `tab2.y = tab1.x`, because the index-scan machinery expects to see the indexed column on the left of the operator it is given. PostgreSQL will *not* simply assume that this is a valid transformation — the creator of the `=` operator must specify that it is valid, by marking the operator with commutator information.

When you are defining a self-commutative operator, you just do it. When you are defining a pair of commutative operators, things are a little trickier: how can the first one to be defined refer to the other one, which you haven't defined yet? There are two solutions to this problem:

- One way is to omit the `COMMUTATOR` clause in the first operator that you define, and then provide one in the second operator's definition. Since PostgreSQL knows that commutative operators come in pairs, when it sees the second definition it will automatically go back and fill in the missing `COMMUTATOR` clause in the first definition.
- The other, more straightforward way is just to include `COMMUTATOR` clauses in both definitions. When PostgreSQL processes the first definition and realizes that `COMMUTATOR` refers to a nonexistent operator, the system will make a dummy entry for that operator in the system catalog. This dummy entry will have valid data only for the operator name, left and right operand types, and result type, since that's all that PostgreSQL can deduce at this point. The first operator's catalog entry will link to this dummy entry. Later, when you define the second operator, the system updates the dummy entry with the additional information from the second definition. If you try to use the dummy operator before it's been filled in, you'll just get an error message.

### 34.13.2. NEGATOR

The `NEGATOR` clause, if provided, names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and  $(x \text{ A } y)$  equals `NOT (x B y)` for all possible inputs  $x, y$ . Notice that B is also the negator of A. For example, `<` and `>=` are a negator pair for most data types. An operator can never validly be its own negator.

Unlike commutators, a pair of unary operators could validly be marked as each others' negators; that would mean  $(A \ x)$  equals `NOT (B x)` for all  $x$ , or the equivalent for right unary operators.

An operator's negator must have the same left and/or right operand types as the operator to be defined, so just as with `COMMUTATOR`, only the operator name need be given in the `NEGATOR` clause.

Providing a negator is very helpful to the query optimizer since it allows expressions like `NOT (x = y)` to be simplified into `x <> y`. This comes up more often than you might think, because `NOT` operations can be inserted as a consequence of other rearrangements.

Pairs of negator operators can be defined using the same methods explained above for commutator pairs.

### 34.13.3. RESTRICT

The `RESTRICT` clause, if provided, names a restriction selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `RESTRICT` clauses only make sense for binary operators that return `boolean`. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a `WHERE`-clause condition of the form:

```
column OP constant
```

for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by `WHERE` clauses that have this form. (What happens if the constant is on the left, you might be wondering? Well, that's one of the things that `COMMUTATOR` is for...)

Writing new restriction selectivity estimation functions is far beyond the scope of this chapter, but fortunately you can usually just use one of the system's standard estimators for many of your own operators. These are the standard restriction estimators:

```
eqsel for =
neqsel for <>
scalarltsel for < or <=
scalargtsel for > or >=
```

It might seem a little odd that these are the categories, but they make sense if you think about it. `=` will typically accept only a small fraction of the rows in a table; `<>` will typically reject only a small fraction. `<` will accept a fraction that depends on where the given constant falls in the range of values for that table column (which, it just so happens, is information collected by `ANALYZE` and made available to the selectivity estimator). `<=` will accept a slightly larger fraction than `<` for the same comparison constant, but they're close enough to not be worth distinguishing, especially since we're not likely to do better than a rough guess anyhow. Similar remarks apply to `>` and `>=`.

You can frequently get away with using either `eqsel` or `neqsel` for operators that have very high or very low selectivity, even if they aren't really equality or inequality. For example, the approximate-equality geometric operators use `eqsel` on the assumption that they'll usually only match a small fraction of the entries in a table.

You can use `scalarltsel` and `scalargtsel` for comparisons on data types that have some sensible means of being converted into numeric scalars for range comparisons. If possible, add the data type to those understood by the function `convert_to_scalar()` in `src/backend/utils/adtselfuncs.c`. (Eventually, this function should be replaced by per-data-type functions identified through a column of the `pg_type` system catalog; but that hasn't happened yet.) If you do not do this, things will still work, but the optimizer's estimates won't be as good as they could be.

There are additional selectivity estimation functions designed for geometric operators in `src/backend/utils/adtt/geo_selfuncs.c`: `areasel`, `positionsel`, and `contsel`. At this writing these are just stubs, but you might want to use them (or even better, improve them) anyway.

### 34.13.4. JOIN

The `JOIN` clause, if provided, names a join selectivity estimation function for the operator. (Note that this is a function name, not an operator name.) `JOIN` clauses only make sense for binary operators that return `boolean`. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a `WHERE`-clause condition of the form:

```
table1.column1 OP table2.column2
```

for the current operator. As with the `RESTRICT` clause, this helps the optimizer very substantially by letting it figure out which of several possible join sequences is likely to take the least work.

As before, this chapter will make no attempt to explain how to write a join selectivity estimator function, but will just suggest that you use one of the standard estimators if one is applicable:

```
eqjoinsel for =
neqjoinsel for <>
scalartltjoinsel for < or <=
scalartgtjoinsel for > or >=
areajoinsel for 2D area-based comparisons
positionjoinsel for 2D position-based comparisons
contjoinsel for 2D containment-based comparisons
```

### 34.13.5. HASHES

The `HASHES` clause, if present, tells the system that it is permissible to use the hash join method for a join based on this operator. `HASHES` only makes sense for a binary operator that returns `boolean`, and in practice the operator must represent equality for some data type or pair of data types.

The assumption underlying hash join is that the join operator can only return true for pairs of left and right values that hash to the same hash code. If two values get put in different hash buckets, the join will never compare them at all, implicitly assuming that the result of the join operator must be false. So it never makes sense to specify `HASHES` for operators that do not represent some form of equality. In most cases it is only practical to support hashing for operators that take the same data type on both sides. However, sometimes it is possible to design compatible hash functions for two or more data types; that is, functions that will generate the same hash codes for “equal” values, even though the values have different representations. For example, it’s fairly simple to arrange this property when hashing integers of different widths.

To be marked `HASHES`, the join operator must appear in a hash index operator family. This is not enforced when you create the operator, since of course the referencing operator family couldn’t exist yet. But attempts to use the operator in hash joins will fail at run time if no such operator family exists. The system needs the operator family to find the data-type-specific hash function(s) for the operator’s input

data type(s). Of course, you must also create suitable hash functions before you can create the operator family.

Care should be exercised when preparing a hash function, because there are machine-dependent ways in which it might fail to do the right thing. For example, if your data type is a structure in which there might be uninteresting pad bits, you cannot simply pass the whole structure to `hash_any`. (Unless you write your other operators and functions to ensure that the unused bits are always zero, which is the recommended strategy.) Another example is that on machines that meet the IEEE floating-point standard, negative zero and positive zero are different values (different bit patterns) but they are defined to compare equal. If a float value might contain negative zero then extra steps are needed to ensure it generates the same hash value as positive zero.

A hash-joinable operator must have a commutator (itself if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. If this is not the case, planner errors might occur when the operator is used. Also, it is a good idea (but not strictly required) for a hash operator family that supports multiple data types to provide equality operators for every combination of the data types; this allows better optimization.

**Note:** The function underlying a hash-joinable operator must be marked immutable or stable. If it is volatile, the system will never attempt to use the operator for a hash join.

**Note:** If a hash-joinable operator has an underlying function that is marked strict, the function must also be complete: that is, it should return true or false, never null, for any two nonnull inputs. If this rule is not followed, hash-optimization of `IN` operations might generate wrong results. (Specifically, `IN` might return false where the correct answer according to the standard would be null; or it might yield an error complaining that it wasn't prepared for a null result.)

### 34.13.6. MERGES

The `MERGES` clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. `MERGES` only makes sense for a binary operator that returns `boolean`, and in practice the operator must represent equality for some data type or pair of data types.

Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the “same place” in the sort order. In practice this means that the join operator must behave like equality. But it is possible to merge-join two distinct data types so long as they are logically compatible. For example, the `smallint-versus-integer` equality operator is merge-joinable. We only need sorting operators that will bring both data types into a logically compatible sequence.

To be marked `MERGES`, the join operator must appear as an equality member of a btree index operator family. This is not enforced when you create the operator, since of course the referencing operator family couldn't exist yet. But the operator will not actually be used for merge joins unless a matching operator family can be found. The `MERGES` flag thus acts as a hint to the planner that it's worth looking for a matching operator family.

A merge-joinable operator must have a commutator (itself if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. If this is not the case, planner errors might occur when the operator is used. Also, it is a good idea (but not strictly required) for a btree operator family that supports multiple data types to provide equality operators for every combination of the data types; this allows better optimization.

**Note:** The function underlying a merge-joinable operator must be marked immutable or stable. If it is volatile, the system will never attempt to use the operator for a merge join.

## 34.14. Interfacing Extensions To Indexes

The procedures described thus far let you define new types, new functions, and new operators. However, we cannot yet define an index on a column of a new data type. To do this, we must define an *operator class* for the new data type. Later in this section, we will illustrate this concept in an example: a new operator class for the B-tree index method that stores and sorts complex numbers in ascending absolute value order.

Operator classes can be grouped into *operator families* to show the relationships between semantically compatible classes. When only a single data type is involved, an operator class is sufficient, so we'll focus on that case first and then return to operator families.

### 34.14.1. Index Methods and Operator Classes

The `pg_am` table contains one row for every index method (internally known as access method). Support for regular access to tables is built into PostgreSQL, but all index methods are described in `pg_am`. It is possible to add a new index method by defining the required interface routines and then creating a row in `pg_am` — but that is beyond the scope of this chapter (see Chapter 50).

The routines for an index method do not directly know anything about the data types that the index method will operate on. Instead, an *operator class* identifies the set of operations that the index method needs to use to work with a particular data type. Operator classes are so called because one thing they specify is the set of `WHERE`-clause operators that can be used with an index (i.e., can be converted into an index-scan qualification). An operator class can also specify some *support procedures* that are needed by the internal operations of the index method, but do not directly correspond to any `WHERE`-clause operator that can be used with the index.

It is possible to define multiple operator classes for the same data type and index method. By doing this, multiple sets of indexing semantics can be defined for a single data type. For example, a B-tree index requires a sort ordering to be defined for each data type it works on. It might be useful for a complex-number data type to have one B-tree operator class that sorts the data by complex absolute value, another that sorts by real part, and so on. Typically, one of the operator classes will be deemed most commonly useful and will be marked as the default operator class for that data type and index method.

The same operator class name can be used for several different index methods (for example, both B-tree and hash index methods have operator classes named `int4_ops`), but each such class is an independent entity and must be defined separately.

### 34.14.2. Index Method Strategies

The operators associated with an operator class are identified by “strategy numbers”, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like “less than” and “greater than or equal to” are interesting with respect to a B-tree. Because PostgreSQL allows the user to define operators, PostgreSQL cannot look at the name of an operator (e.g., `<` or `>=`) and tell what kind of comparison it is. Instead, the index method defines a set of “strategies”, which can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics.

The B-tree index method defines five strategies, shown in Table 34-2.

**Table 34-2. B-tree Strategies**

Operation	Strategy Number
less than	1
less than or equal	2
equal	3
greater than or equal	4
greater than	5

Hash indexes support only equality comparisons, and so they use only one strategy, shown in Table 34-3.

**Table 34-3. Hash Strategies**

Operation	Strategy Number
equal	1

GiST indexes are more flexible: they do not have a fixed set of strategies at all. Instead, the “consistency” support routine of each particular GiST operator class interprets the strategy numbers however it likes. As an example, several of the built-in GiST index operator classes index two-dimensional geometric objects, providing the “R-tree” strategies shown in Table 34-4. Four of these are true two-dimensional tests (overlaps, same, contains, contained by); four of them consider only the X direction; and the other four provide the same tests in the Y direction.

**Table 34-4. GiST Two-Dimensional “R-tree” Strategies**

Operation	Strategy Number
strictly left of	1
does not extend to right of	2
overlaps	3
does not extend to left of	4
strictly right of	5
same	6
contains	7

Operation	Strategy Number
contained by	8
does not extend above	9
strictly below	10
strictly above	11
does not extend below	12

GIN indexes are similar to GiST indexes in flexibility: they don't have a fixed set of strategies. Instead the support routines of each operator class interpret the strategy numbers according to the operator class's definition. As an example, the strategy numbers used by the built-in operator classes for arrays are shown in Table 34-5.

**Table 34-5. GIN Array Strategies**

Operation	Strategy Number
overlap	1
contains	2
is contained by	3
equal	4

Notice that all strategy operators return Boolean values. In practice, all operators defined as index method strategies must return type `boolean`, since they must appear at the top level of a `WHERE` clause to be used with an index.

### 34.14.3. Index Method Support Routines

Strategies aren't usually enough information for the system to figure out how to use an index. In practice, the index methods require additional support routines in order to work. For example, the B-tree index method must be able to compare two keys and determine whether one is greater than, equal to, or less than the other. Similarly, the hash index method must be able to compute hash codes for key values. These operations do not correspond to operators used in qualifications in SQL commands; they are administrative routines used by the index methods, internally.

Just as with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the "support function numbers" specified by the index method.

B-trees require a single support function, shown in Table 34-6.

**Table 34-6. B-tree Support Functions**

Function	Support Number
----------	----------------

Function	Support Number
Compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second	1

Hash indexes likewise require one support function, shown in Table 34-7.

**Table 34-7. Hash Support Functions**

Function	Support Number
Compute the hash value for a key	1

GiST indexes require seven support functions, shown in Table 34-8.

**Table 34-8. GiST Support Functions**

Function	Support Number
consistent - determine whether key satisfies the query qualifier	1
union - compute union of a set of keys	2
compress - compute a compressed representation of a key or value to be indexed	3
decompress - compute a decompressed representation of a compressed key	4
penalty - compute penalty for inserting new key into subtree with given subtree's key	5
picksplit - determine which entries of a page are to be moved to the new page and compute the union keys for resulting pages	6
equal - compare two keys and return true if they are equal	7

GIN indexes require four support functions, shown in Table 34-9.

**Table 34-9. GIN Support Functions**

Function	Support Number
compare - compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second	1
extractValue - extract keys from a value to be indexed	2
extractQuery - extract keys from a query condition	3

Function	Support Number
consistent - determine whether value matches query condition	4

Unlike strategy operators, support functions return whichever data type the particular index method expects; for example in the case of the comparison function for B-trees, a signed integer. The number and types of the arguments to each support function are likewise dependent on the index method. For B-tree and hash the support functions take the same input data types as do the operators included in the operator class, but this is not the case for most GIN and GiST support functions.

### 34.14.4. An Example

Now that we have seen the ideas, here is the promised example of creating a new operator class. (You can find a working copy of this example in `src/tutorial/complex.c` and `src/tutorial/complex.sql` in the source distribution.) The operator class encapsulates operators that sort complex numbers in absolute value order, so we choose the name `complex_abs_ops`. First, we need a set of operators. The procedure for defining operators was discussed in Section 34.12. For an operator class on B-trees, the operators we require are:

- absolute-value less-than (strategy 1)
- absolute-value less-than-or-equal (strategy 2)
- absolute-value equal (strategy 3)
- absolute-value greater-than-or-equal (strategy 4)
- absolute-value greater-than (strategy 5)

The least error-prone way to define a related set of comparison operators is to write the B-tree comparison support function first, and then write the other functions as one-line wrappers around the support function. This reduces the odds of getting inconsistent results for corner cases. Following this approach, we first write:

```
#define Mag(c) ((c)->x*(c)->x + (c)->y*(c)->y)

static int
complex_abs_cmp_internal(Complex *a, Complex *b)
{
    double    amag = Mag(a),
             bmag = Mag(b);

    if (amag < bmag)
        return -1;
    if (amag > bmag)
        return 1;
    return 0;
}
```

Now the less-than function looks like:

```
PG_FUNCTION_INFO_V1(complex_abs_lt);

Datum
complex_abs_lt(PG_FUNCTION_ARGS)
{
    Complex    *a = (Complex *) PG_GETARG_POINTER(0);
    Complex    *b = (Complex *) PG_GETARG_POINTER(1);

    PG_RETURN_BOOL(complex_abs_cmp_internal(a, b) < 0);
}
```

The other four functions differ only in how they compare the internal function's result to zero.

Next we declare the functions and the operators based on the functions to SQL:

```
CREATE FUNCTION complex_abs_lt(complex, complex) RETURNS bool
    AS 'filename', 'complex_abs_lt'
    LANGUAGE C IMMUTABLE STRICT;

CREATE OPERATOR < (
    leftarg = complex, rightarg = complex, procedure = complex_abs_lt,
    commutator = > , negator = >= ,
    restrict = scalarltsel, join = scalarltjoinsel
);
```

It is important to specify the correct commutator and negator operators, as well as suitable restriction and join selectivity functions, otherwise the optimizer will be unable to make effective use of the index. Note that the less-than, equal, and greater-than cases should use different selectivity functions.

Other things worth noting are happening here:

- There can only be one operator named, say, = and taking type `complex` for both operands. In this case we don't have any other operator = for `complex`, but if we were building a practical data type we'd probably want = to be the ordinary equality operation for complex numbers (and not the equality of the absolute values). In that case, we'd need to use some other operator name for `complex_abs_eq`.
- Although PostgreSQL can cope with functions having the same SQL name as long as they have different argument data types, C can only cope with one global function having a given name. So we shouldn't name the C function something simple like `abs_eq`. Usually it's a good practice to include the data type name in the C function name, so as not to conflict with functions for other data types.
- We could have made the SQL name of the function `abs_eq`, relying on PostgreSQL to distinguish it by argument data types from any other SQL function of the same name. To keep the example simple, we make the function have the same names at the C level and SQL level.

The next step is the registration of the support routine required by B-trees. The example C code that implements this is in the same file that contains the operator functions. This is how we declare the function:

```
CREATE FUNCTION complex_abs_cmp(complex, complex)
    RETURNS integer
    AS 'filename'
    LANGUAGE C IMMUTABLE STRICT;
```

Now that we have the required operators and support routine, we can finally create the operator class:

```
CREATE OPERATOR CLASS complex_abs_ops
    DEFAULT FOR TYPE complex USING btree AS
        OPERATOR          1          < ,
        OPERATOR          2          <= ,
        OPERATOR          3          = ,
        OPERATOR          4          >= ,
        OPERATOR          5          > ,
        FUNCTION           1          complex_abs_cmp(complex, complex);
```

And we're done! It should now be possible to create and use B-tree indexes on `complex` columns.

We could have written the operator entries more verbosely, as in:

```
OPERATOR          1          < (complex, complex) ,
```

but there is no need to do so when the operators take the same data type we are defining the operator class for.

The above example assumes that you want to make this new operator class the default B-tree operator class for the `complex` data type. If you don't, just leave out the word `DEFAULT`.

### 34.14.5. Operator Classes and Operator Families

So far we have implicitly assumed that an operator class deals with only one data type. While there certainly can be only one data type in a particular index column, it is often useful to index operations that compare an indexed column to a value of a different data type. Also, if there is use for a cross-data-type operator in connection with an operator class, it is often the case that the other data type has a related operator class of its own. It is helpful to make the connections between related classes explicit, because this can aid the planner in optimizing SQL queries (particularly for B-tree operator classes, since the planner contains a great deal of knowledge about how to work with them).

To handle these needs, PostgreSQL uses the concept of an *operator family*. An operator family contains one or more operator classes, and can also contain indexable operators and corresponding support functions that belong to the family as a whole but not to any single class within the family. We say that such operators and functions are “loose” within the family, as opposed to being bound into a specific class. Typically each operator class contains single-data-type operators while cross-data-type operators are loose in the family.

All the operators and functions in an operator family must have compatible semantics, where the compatibility requirements are set by the index method. You might therefore wonder why bother to single out particular subsets of the family as operator classes; and indeed for many purposes the class divisions are irrelevant and the family is the only interesting grouping. The reason for defining operator classes is that they specify how much of the family is needed to support any particular index. If there is an index using an operator class, then that operator class cannot be dropped without dropping the index — but other parts of the operator family, namely other operator classes and loose operators, could be dropped. Thus, an operator class should be specified to contain the minimum set of operators and functions that are reasonably

needed to work with an index on a specific data type, and then related but non-essential operators can be added as loose members of the operator family.

As an example, PostgreSQL has a built-in B-tree operator family `integer_ops`, which includes operator classes `int8_ops`, `int4_ops`, and `int2_ops` for indexes on `bigint` (`int8`), `integer` (`int4`), and `smallint` (`int2`) columns respectively. The family also contains cross-data-type comparison operators allowing any two of these types to be compared, so that an index on one of these types can be searched using a comparison value of another type. The family could be duplicated by these definitions:

```
CREATE OPERATOR FAMILY integer_ops USING btree;

CREATE OPERATOR CLASS int8_ops
DEFAULT FOR TYPE int8 USING btree FAMILY integer_ops AS
    -- standard int8 comparisons
    OPERATOR 1 < ,
    OPERATOR 2 <= ,
    OPERATOR 3 = ,
    OPERATOR 4 >= ,
    OPERATOR 5 > ,
    FUNCTION 1 btint8cmp(int8, int8) ;

CREATE OPERATOR CLASS int4_ops
DEFAULT FOR TYPE int4 USING btree FAMILY integer_ops AS
    -- standard int4 comparisons
    OPERATOR 1 < ,
    OPERATOR 2 <= ,
    OPERATOR 3 = ,
    OPERATOR 4 >= ,
    OPERATOR 5 > ,
    FUNCTION 1 btint4cmp(int4, int4) ;

CREATE OPERATOR CLASS int2_ops
DEFAULT FOR TYPE int2 USING btree FAMILY integer_ops AS
    -- standard int2 comparisons
    OPERATOR 1 < ,
    OPERATOR 2 <= ,
    OPERATOR 3 = ,
    OPERATOR 4 >= ,
    OPERATOR 5 > ,
    FUNCTION 1 btint2cmp(int2, int2) ;

```

Notice that this definition “overloads” the operator strategy and support function numbers: each number occurs multiple times within the family. This is allowed so long as each instance of a particular number has distinct input data types. The instances that have both input types equal to an operator class’s input type are the primary operators and support functions for that operator class, and in most cases should be declared as part of the operator class rather than as loose members of the family.

In a B-tree operator family, all the operators in the family must sort compatibly, meaning that the transitive laws hold across all the data types supported by the family: “if  $A = B$  and  $B = C$ , then  $A = C$ ”, and “if  $A < B$  and  $B < C$ , then  $A < C$ ”. For each operator in the family there must be a support function having the same two input data types as the operator. It is recommended that a family be complete, i.e., for each combination of data types, all operators are included. Each operator class should include just the non-cross-type operators and support function for its data type.

To build a multiple-data-type hash operator family, compatible hash support functions must be created for each data type supported by the family. Here compatibility means that the functions are guaranteed to return the same hash code for any two values that are considered equal by the family’s equality operators,

even when the values are of different types. This is usually difficult to accomplish when the types have different physical representations, but it can be done in some cases. Notice that there is only one support function per data type, not one per equality operator. It is recommended that a family be complete, i.e., provide an equality operator for each combination of data types. Each operator class should include just the non-cross-type equality operator and the support function for its data type.

GIN and GiST indexes do not have any explicit notion of cross-data-type operations. The set of operators supported is just whatever the primary support functions for a given operator class can handle.

**Note:** Prior to PostgreSQL 8.3, there was no concept of operator families, and so any cross-data-type operators intended to be used with an index had to be bound directly into the index's operator class. While this approach still works, it is deprecated because it makes an index's dependencies too broad, and because the planner can handle cross-data-type comparisons more effectively when both data types have operators in the same operator family.

### 34.14.6. System Dependencies on Operator Classes

PostgreSQL uses operator classes to infer the properties of operators in more ways than just whether they can be used with indexes. Therefore, you might want to create operator classes even if you have no intention of indexing any columns of your data type.

In particular, there are SQL features such as `ORDER BY` and `DISTINCT` that require comparison and sorting of values. To implement these features on a user-defined data type, PostgreSQL looks for the default B-tree operator class for the data type. The “equals” member of this operator class defines the system's notion of equality of values for `GROUP BY` and `DISTINCT`, and the sort ordering imposed by the operator class defines the default `ORDER BY` ordering.

Comparison of arrays of user-defined types also relies on the semantics defined by the default B-tree operator class.

If there is no default B-tree operator class for a data type, the system will look for a default hash operator class. But since that kind of operator class only provides equality, in practice it is only enough to support array equality.

When there is no default operator class for a data type, you will get errors like “could not identify an ordering operator” if you try to use these SQL features with the data type.

**Note:** In PostgreSQL versions before 7.4, sorting and grouping operations would implicitly use operators named `=`, `<`, and `>`. The new behavior of relying on default operator classes avoids having to make any assumption about the behavior of operators with particular names.

Another important point is that an operator that appears in a hash operator family is a candidate for hash joins, hash aggregation, and related optimizations. The hash operator family is essential here since it identifies the hash function(s) to use.

### 34.14.7. Special Features of Operator Classes

There are two special features of operator classes that we have not discussed yet, mainly because they are not useful with the most commonly used index methods.

Normally, declaring an operator as a member of an operator class (or family) means that the index method can retrieve exactly the set of rows that satisfy a `WHERE` condition using the operator. For example:

```
SELECT * FROM table WHERE integer_column < 4;
```

can be satisfied exactly by a B-tree index on the integer column. But there are cases where an index is useful as an inexact guide to the matching rows. For example, if a GiST index stores only bounding boxes for objects, then it cannot exactly satisfy a `WHERE` condition that tests overlap between nonrectangular objects such as polygons. Yet we could use the index to find objects whose bounding box overlaps the bounding box of the target object, and then do the exact overlap test only on the objects found by the index. If this scenario applies, the index is said to be “lossy” for the operator, and we add `RECHECK` to the `OPERATOR` clause in the `CREATE OPERATOR CLASS` command. `RECHECK` is valid if the index is guaranteed to return all the required rows, plus perhaps some additional rows, which can be eliminated by performing the original operator invocation.

Consider again the situation where we are storing in the index only the bounding box of a complex object such as a polygon. In this case there’s not much value in storing the whole polygon in the index entry — we might as well store just a simpler object of type `box`. This situation is expressed by the `STORAGE` option in `CREATE OPERATOR CLASS`: we’d write something like:

```
CREATE OPERATOR CLASS polygon_ops
    DEFAULT FOR TYPE polygon USING gist AS
    ...
    STORAGE box;
```

At present, only the GiST and GIN index methods support a `STORAGE` type that’s different from the column data type. The GiST `compress` and `decompress` support routines must deal with data-type conversion when `STORAGE` is used. In GIN, the `STORAGE` type identifies the type of the “key” values, which normally is different from the type of the indexed column — for example, an operator class for integer-array columns might have keys that are just integers. The GIN `extractValue` and `extractQuery` support routines are responsible for extracting keys from indexed values.

# Chapter 35. Triggers

This chapter provides general information about writing trigger functions. Trigger functions can be written in most of the available procedural languages, including PL/pgSQL (Chapter 38), PL/Tcl (Chapter 39), PL/Perl (Chapter 40), and PL/Python (Chapter 41). After reading this chapter, you should consult the chapter for your favorite procedural language to find out the language-specific details of writing a trigger in it.

It is also possible to write a trigger function in C, although most people find it easier to use one of the procedural languages. It is not currently possible to write a trigger function in the plain SQL function language.

## 35.1. Overview of Trigger Behavior

A trigger is a specification that the database should automatically execute a particular function whenever a certain type of operation is performed. Triggers can be defined to execute either before or after any `INSERT`, `UPDATE`, or `DELETE` operation, either once per modified row, or once per SQL statement. If a trigger event occurs, the trigger's function is called at the appropriate time to handle the event.

The trigger function must be defined before the trigger itself can be created. The trigger function must be declared as a function taking no arguments and returning type `trigger`. (The trigger function receives its input through a specially-passed `TriggerData` structure, not in the form of ordinary function arguments.)

Once a suitable trigger function has been created, the trigger is established with `CREATE TRIGGER`. The same trigger function can be used for multiple triggers.

PostgreSQL offers both *per-row* triggers and *per-statement* triggers. With a per-row trigger, the trigger function is invoked once for each row that is affected by the statement that fired the trigger. In contrast, a per-statement trigger is invoked only once when an appropriate statement is executed, regardless of the number of rows affected by that statement. In particular, a statement that affects zero rows will still result in the execution of any applicable per-statement triggers. These two types of triggers are sometimes called *row-level* triggers and *statement-level* triggers, respectively.

Triggers are also classified as *before* triggers and *after* triggers. Statement-level before triggers naturally fire before the statement starts to do anything, while statement-level after triggers fire at the very end of the statement. Row-level before triggers fire immediately before a particular row is operated on, while row-level after triggers fire at the end of the statement (but before any statement-level after triggers).

Trigger functions invoked by per-statement triggers should always return `NULL`. Trigger functions invoked by per-row triggers can return a table row (a value of type `HeapTuple`) to the calling executor, if they choose. A row-level trigger fired before an operation has the following choices:

- It can return `NULL` to skip the operation for the current row. This instructs the executor to not perform the row-level operation that invoked the trigger (the insertion or modification of a particular table row).
- For row-level `INSERT` and `UPDATE` triggers only, the returned row becomes the row that will be inserted or will replace the row being updated. This allows the trigger function to modify the row being inserted or updated.

A row-level before trigger that does not intend to cause either of these behaviors must be careful to return as its result the same row that was passed in (that is, the `NEW` row for `INSERT` and `UPDATE` triggers, the `OLD` row for `DELETE` triggers).

The return value is ignored for row-level triggers fired after an operation, and so they can return `NULL`.

If more than one trigger is defined for the same event on the same relation, the triggers will be fired in alphabetical order by trigger name. In the case of before triggers, the possibly-modified row returned by each trigger becomes the input to the next trigger. If any before trigger returns `NULL`, the operation is abandoned for that row and subsequent triggers are not fired.

Typically, row before triggers are used for checking or modifying the data that will be inserted or updated. For example, a before trigger might be used to insert the current time into a `timestamp` column, or to check that two elements of the row are consistent. Row after triggers are most sensibly used to propagate the updates to other tables, or make consistency checks against other tables. The reason for this division of labor is that an after trigger can be certain it is seeing the final value of the row, while a before trigger cannot; there might be other before triggers firing after it. If you have no specific reason to make a trigger before or after, the before case is more efficient, since the information about the operation doesn't have to be saved until end of statement.

If a trigger function executes SQL commands then these commands might fire triggers again. This is known as cascading triggers. There is no direct limitation on the number of cascade levels. It is possible for cascades to cause a recursive invocation of the same trigger; for example, an `INSERT` trigger might execute a command that inserts an additional row into the same table, causing the `INSERT` trigger to be fired again. It is the trigger programmer's responsibility to avoid infinite recursion in such scenarios.

When a trigger is being defined, arguments can be specified for it. The purpose of including arguments in the trigger definition is to allow different triggers with similar requirements to call the same function. As an example, there could be a generalized trigger function that takes as its arguments two column names and puts the current user in one and the current time stamp in the other. Properly written, this trigger function would be independent of the specific table it is triggering on. So the same function could be used for `INSERT` events on any table with suitable columns, to automatically track creation of records in a transaction table for example. It could also be used to track last-update events if defined as an `UPDATE` trigger.

Each programming language that supports triggers has its own method for making the trigger input data available to the trigger function. This input data includes the type of trigger event (e.g., `INSERT` or `UPDATE`) as well as any arguments that were listed in `CREATE TRIGGER`. For a row-level trigger, the input data also includes the `NEW` row for `INSERT` and `UPDATE` triggers, and/or the `OLD` row for `UPDATE` and `DELETE` triggers. Statement-level triggers do not currently have any way to examine the individual row(s) modified by the statement.

## 35.2. Visibility of Data Changes

If you execute SQL commands in your trigger function, and these commands access the table that the trigger is for, then you need to be aware of the data visibility rules, because they determine whether these SQL commands will see the data change that the trigger is fired for. Briefly:

- Statement-level triggers follow simple visibility rules: none of the changes made by a statement are

visible to statement-level triggers that are invoked before the statement, whereas all modifications are visible to statement-level after triggers.

- The data change (insertion, update, or deletion) causing the trigger to fire is naturally *not* visible to SQL commands executed in a row-level before trigger, because it hasn't happened yet.
- However, SQL commands executed in a row-level before trigger *will* see the effects of data changes for rows previously processed in the same outer command. This requires caution, since the ordering of these change events is not in general predictable; a SQL command that affects multiple rows can visit the rows in any order.
- When a row-level after trigger is fired, all data changes made by the outer command are already complete, and are visible to the invoked trigger function.

Further information about data visibility rules can be found in Section 42.4. The example in Section 35.4 contains a demonstration of these rules.

## 35.3. Writing Trigger Functions in C

This section describes the low-level details of the interface to a trigger function. This information is only needed when writing trigger functions in C. If you are using a higher-level language then these details are handled for you. In most cases you should consider using a procedural language before writing your triggers in C. The documentation of each procedural language explains how to write a trigger in that language.

Trigger functions must use the “version 1” function manager interface.

When a function is called by the trigger manager, it is not passed any normal arguments, but it is passed a “context” pointer pointing to a `TriggerData` structure. C functions can check whether they were called from the trigger manager or not by executing the macro:

```
CALLED_AS_TRIGGER(fcinfo)
```

which expands to:

```
((fcinfo)->context != NULL && IsA((fcinfo)->context, TriggerData))
```

If this returns true, then it is safe to cast `fcinfo->context` to type `TriggerData *` and make use of the pointed-to `TriggerData` structure. The function must *not* alter the `TriggerData` structure or any of the data it points to.

`struct TriggerData` is defined in `commands/trigger.h`:

```
typedef struct TriggerData
{
    NodeTag      type;
    TriggerEvent tg_event;
    Relation     tg_relation;
    HeapTuple    tg_trigtuple;
    HeapTuple    tg_newtuple;
    Trigger      *tg_trigger;
```

```

    Buffer      tg_trigtuplebuf;
    Buffer      tg_newtuplebuf;
} TriggerData;

```

where the members are defined as follows:

type

Always T\_TriggerData.

tg\_event

Describes the event for which the function is called. You can use the following macros to examine tg\_event:

TRIGGER\_FIRED\_BEFORE(tg\_event)

Returns true if the trigger fired before the operation.

TRIGGER\_FIRED\_AFTER(tg\_event)

Returns true if the trigger fired after the operation.

TRIGGER\_FIRED\_FOR\_ROW(tg\_event)

Returns true if the trigger fired for a row-level event.

TRIGGER\_FIRED\_FOR\_STATEMENT(tg\_event)

Returns true if the trigger fired for a statement-level event.

TRIGGER\_FIRED\_BY\_INSERT(tg\_event)

Returns true if the trigger was fired by an INSERT command.

TRIGGER\_FIRED\_BY\_UPDATE(tg\_event)

Returns true if the trigger was fired by an UPDATE command.

TRIGGER\_FIRED\_BY\_DELETE(tg\_event)

Returns true if the trigger was fired by a DELETE command.

tg\_relation

A pointer to a structure describing the relation that the trigger fired for. Look at `utils/rel.h` for details about this structure. The most interesting things are `tg_relation->rd_att` (descriptor of the relation tuples) and `tg_relation->rd_rel->relname` (relation name; the type is not `char*` but `NameData`; use `SPI_getrelname(tg_relation)` to get a `char*` if you need a copy of the name).

tg\_trigtuple

A pointer to the row for which the trigger was fired. This is the row being inserted, updated, or deleted. If this trigger was fired for an INSERT or DELETE then this is what you should return from the function if you don't want to replace the row with a different one (in the case of INSERT) or skip the operation.

`tg_newtuple`

A pointer to the new version of the row, if the trigger was fired for an `UPDATE`, and `NULL` if it is for an `INSERT` or a `DELETE`. This is what you have to return from the function if the event is an `UPDATE` and you don't want to replace this row by a different one or skip the operation.

`tg_trigger`

A pointer to a structure of type `Trigger`, defined in `utils/rel.h`:

```
typedef struct Trigger
{
    Oid          tgoid;
    char         *tgname;
    Oid          tgfoid;
    int16        tgtype;
    bool         tgenabled;
    bool         tgisconstraint;
    Oid          tgconstrrelid;
    Oid          tgconstraint;
    bool         tgdeferrable;
    bool         tginitdeferred;
    int16        tgnargs;
    int16        tgnattr;
    int16        *tgattr;
    char         **tgargs;
} Trigger;
```

where `tgname` is the trigger's name, `tgnargs` is number of arguments in `tgargs`, and `tgargs` is an array of pointers to the arguments specified in the `CREATE TRIGGER` statement. The other members are for internal use only.

`tg_trigtuplebuf`

The buffer containing `tg_trigtuple`, or `InvalidBuffer` if there is no such tuple or it is not stored in a disk buffer.

`tg_newtuplebuf`

The buffer containing `tg_newtuple`, or `InvalidBuffer` if there is no such tuple or it is not stored in a disk buffer.

A trigger function must return either a `HeapTuple` pointer or a `NULL` pointer (*not* an SQL null value, that is, do not set `isNull` true). Be careful to return either `tg_trigtuple` or `tg_newtuple`, as appropriate, if you don't want to modify the row being operated on.

## 35.4. A Complete Example

Here is a very simple example of a trigger function written in C. (Examples of triggers written in procedural languages can be found in the documentation of the procedural languages.)

The function `trigf` reports the number of rows in the table `ttest` and skips the actual operation if the command attempts to insert a null value into the column `x`. (So the trigger acts as a not-null constraint but doesn't abort the transaction.)

First, the table definition:

```
CREATE TABLE ttest (
    x integer
);
```

This is the source code of the trigger function:

```
#include "postgres.h"
#include "executor/spi.h"      /* this is what you need to work with SPI */
#include "commands/trigger.h" /* ... and triggers */

extern Datum trigf(PG_FUNCTION_ARGS);

PG_FUNCTION_INFO_V1(trigf);

Datum
trigf(PG_FUNCTION_ARGS)
{
    TriggerData *trigdata = (TriggerData *) fcinfo->context;
    TupleDesc   tupdesc;
    HeapTuple   rettuplet;
    char        *when;
    bool        checknull = false;
    bool        isnull;
    int         ret, i;

    /* make sure it's called as a trigger at all */
    if (!CALLED_AS_TRIGGER(fcinfo))
        elog(ERROR, "trigf: not called by trigger manager");

    /* tuple to return to executor */
    if (TRIGGER_FIRED_BY_UPDATE(trigdata->tg_event))
        rettuplet = trigdata->tg_newtuple;
    else
        rettuplet = trigdata->tg_trigtuple;

    /* check for null values */
    if (!TRIGGER_FIRED_BY_DELETE(trigdata->tg_event)
        && TRIGGER_FIRED_BEFORE(trigdata->tg_event))
        checknull = true;

    if (TRIGGER_FIRED_BEFORE(trigdata->tg_event))
        when = "before";
    else
        when = "after ";

    tupdesc = trigdata->tg_relation->rd_att;

    /* connect to SPI manager */
    if ((ret = SPI_connect()) < 0)
        elog(INFO, "trigf (fired %s): SPI_connect returned %d", when, ret);
```

```

/* get number of rows in table */
ret = SPI_exec("SELECT count(*) FROM ttest", 0);

if (ret < 0)
    elog(NOTICE, "trigf (fired %s): SPI_exec returned %d", when, ret);

/* count(*) returns int8, so be careful to convert */
i = DatumGetInt64(SPI_getbinval(SPI_tuptable->vals[0],
                                SPI_tuptable->tupdesc,
                                1,
                                &isnull));

elog (INFO, "trigf (fired %s): there are %d rows in ttest", when, i);

SPI_finish();

if (checknull)
{
    SPI_getbinval(rettuple, tupdesc, 1, &isnull);
    if (isnull)
        rettuple = NULL;
}

return PointerGetDatum(rettuple);
}

```

After you have compiled the source code, declare the function and the triggers:

```

CREATE FUNCTION trigf() RETURNS trigger
    AS 'filename'
    LANGUAGE C;

CREATE TRIGGER tbefore BEFORE INSERT OR UPDATE OR DELETE ON ttest
    FOR EACH ROW EXECUTE PROCEDURE trigf();

CREATE TRIGGER tafter AFTER INSERT OR UPDATE OR DELETE ON ttest
    FOR EACH ROW EXECUTE PROCEDURE trigf();

```

Now you can test the operation of the trigger:

```

=> INSERT INTO ttest VALUES (NULL);
INFO:  trigf (fired before): there are 0 rows in ttest
INSERT 0 0

-- Insertion skipped and AFTER trigger is not fired

=> SELECT * FROM ttest;
x
---
```

```

(0 rows)

=> INSERT INTO ttest VALUES (1);
INFO:  trigf (fired before): there are 0 rows in ttest
INFO:  trigf (fired after ): there are 1 rows in ttest
      ^^^^^^^^

      remember what we said about visibility.

INSERT 167793 1
vac=> SELECT * FROM ttest;
  x
---
  1
(1 row)

=> INSERT INTO ttest SELECT x * 2 FROM ttest;
INFO:  trigf (fired before): there are 1 rows in ttest
INFO:  trigf (fired after ): there are 2 rows in ttest
      ^^^^^^

      remember what we said about visibility.

INSERT 167794 1
=> SELECT * FROM ttest;
  x
---
  1
  2
(2 rows)

=> UPDATE ttest SET x = NULL WHERE x = 2;
INFO:  trigf (fired before): there are 2 rows in ttest
UPDATE 0
=> UPDATE ttest SET x = 4 WHERE x = 2;
INFO:  trigf (fired before): there are 2 rows in ttest
INFO:  trigf (fired after ): there are 2 rows in ttest
UPDATE 1
vac=> SELECT * FROM ttest;
  x
---
  1
  4
(2 rows)

=> DELETE FROM ttest;
INFO:  trigf (fired before): there are 2 rows in ttest
INFO:  trigf (fired before): there are 1 rows in ttest
INFO:  trigf (fired after ): there are 0 rows in ttest
INFO:  trigf (fired after ): there are 0 rows in ttest
      ^^^^^^

      remember what we said about visibility.

DELETE 2
=> SELECT * FROM ttest;
  x
---
(0 rows)

```

There are more complex examples in `src/test/regress/regress.c` and in `contrib/spi`.

# Chapter 36. The Rule System

This chapter discusses the rule system in PostgreSQL. Production rule systems are conceptually simple, but there are many subtle points involved in actually using them.

Some other database systems define active database rules, which are usually stored procedures and triggers. In PostgreSQL, these can be implemented using functions and triggers as well.

The rule system (more precisely speaking, the query rewrite rule system) is totally different from stored procedures and triggers. It modifies queries to take rules into consideration, and then passes the modified query to the query planner for planning and execution. It is very powerful, and can be used for many things such as query language procedures, views, and versions. The theoretical foundations and the power of this rule system are also discussed in *On Rules, Procedures, Caching and Views in Database Systems* and *A Unified Framework for Version Modeling Using Production Rules in a Database System*.

## 36.1. The Query Tree

To understand how the rule system works it is necessary to know when it is invoked and what its input and results are.

The rule system is located between the parser and the planner. It takes the output of the parser, one query tree, and the user-defined rewrite rules, which are also query trees with some extra information, and creates zero or more query trees as result. So its input and output are always things the parser itself could have produced and thus, anything it sees is basically representable as an SQL statement.

Now what is a query tree? It is an internal representation of an SQL statement where the single parts that it is built from are stored separately. These query trees can be shown in the server log if you set the configuration parameters `debug_print_parse`, `debug_print_rewritten`, or `debug_print_plan`. The rule actions are also stored as query trees, in the system catalog `pg_rewrite`. They are not formatted like the log output, but they contain exactly the same information.

Reading a raw query tree requires some experience. But since SQL representations of query trees are sufficient to understand the rule system, this chapter will not teach how to read them.

When reading the SQL representations of the query trees in this chapter it is necessary to be able to identify the parts the statement is broken into when it is in the query tree structure. The parts of a query tree are

the command type

This is a simple value telling which command (`SELECT`, `INSERT`, `UPDATE`, `DELETE`) produced the query tree.

the range table

The range table is a list of relations that are used in the query. In a `SELECT` statement these are the relations given after the `FROM` key word.

Every range table entry identifies a table or view and tells by which name it is called in the other parts of the query. In the query tree, the range table entries are referenced by number rather than by name, so here it doesn't matter if there are duplicate names as it would in an SQL statement. This

can happen after the range tables of rules have been merged in. The examples in this chapter will not have this situation.

#### the result relation

This is an index into the range table that identifies the relation where the results of the query go.

`SELECT` queries normally don't have a result relation. The special case of a `SELECT INTO` is mostly identical to a `CREATE TABLE` followed by a `INSERT . . . SELECT` and is not discussed separately here.

For `INSERT`, `UPDATE`, and `DELETE` commands, the result relation is the table (or view!) where the changes are to take effect.

#### the target list

The target list is a list of expressions that define the result of the query. In the case of a `SELECT`, these expressions are the ones that build the final output of the query. They correspond to the expressions between the key words `SELECT` and `FROM`. (\* is just an abbreviation for all the column names of a relation. It is expanded by the parser into the individual columns, so the rule system never sees it.)

`DELETE` commands don't need a target list because they don't produce any result. In fact, the planner will add a special CTID entry to the empty target list, but this is after the rule system and will be discussed later; for the rule system, the target list is empty.

For `INSERT` commands, the target list describes the new rows that should go into the result relation. It consists of the expressions in the `VALUES` clause or the ones from the `SELECT` clause in `INSERT . . . SELECT`. The first step of the rewrite process adds target list entries for any columns that were not assigned to by the original command but have defaults. Any remaining columns (with neither a given value nor a default) will be filled in by the planner with a constant null expression.

For `UPDATE` commands, the target list describes the new rows that should replace the old ones. In the rule system, it contains just the expressions from the `SET column = expression` part of the command. The planner will handle missing columns by inserting expressions that copy the values from the old row into the new one. And it will add the special CTID entry just as for `DELETE`, too.

Every entry in the target list contains an expression that can be a constant value, a variable pointing to a column of one of the relations in the range table, a parameter, or an expression tree made of function calls, constants, variables, operators, etc.

#### the qualification

The query's qualification is an expression much like one of those contained in the target list entries. The result value of this expression is a Boolean that tells whether the operation (`INSERT`, `UPDATE`, `DELETE`, or `SELECT`) for the final result row should be executed or not. It corresponds to the `WHERE` clause of an SQL statement.

#### the join tree

The query's join tree shows the structure of the `FROM` clause. For a simple query like `SELECT . . . FROM a, b, c`, the join tree is just a list of the `FROM` items, because we are allowed to join them in any order. But when `JOIN` expressions, particularly outer joins, are used, we have to join in the order shown by the joins. In that case, the join tree shows the structure of the `JOIN` expressions. The restrictions associated with particular `JOIN` clauses (from `ON` or `USING` expressions) are stored as qualification expressions attached to those join-tree nodes. It turns out to be convenient to store the

top-level `WHERE` expression as a qualification attached to the top-level join-tree item, too. So really the join tree represents both the `FROM` and `WHERE` clauses of a `SELECT`.

the others

The other parts of the query tree like the `ORDER BY` clause aren't of interest here. The rule system substitutes some entries there while applying rules, but that doesn't have much to do with the fundamentals of the rule system.

## 36.2. Views and the Rule System

Views in PostgreSQL are implemented using the rule system. In fact, there is essentially no difference between:

```
CREATE VIEW myview AS SELECT * FROM mytab;
```

compared against the two commands:

```
CREATE TABLE myview (same column list as mytab);
CREATE RULE "_RETURN" AS ON SELECT TO myview DO INSTEAD
    SELECT * FROM mytab;
```

because this is exactly what the `CREATE VIEW` command does internally. This has some side effects. One of them is that the information about a view in the PostgreSQL system catalogs is exactly the same as it is for a table. So for the parser, there is absolutely no difference between a table and a view. They are the same thing: relations.

### 36.2.1. How `SELECT` Rules Work

Rules `ON SELECT` are applied to all queries as the last step, even if the command given is an `INSERT`, `UPDATE` or `DELETE`. And they have different semantics from rules on the other command types in that they modify the query tree in place instead of creating a new one. So `SELECT` rules are described first.

Currently, there can be only one action in an `ON SELECT` rule, and it must be an unconditional `SELECT` action that is `INSTEAD`. This restriction was required to make rules safe enough to open them for ordinary users, and it restricts `ON SELECT` rules to act like views.

The examples for this chapter are two join views that do some calculations and some more views using them in turn. One of the two first views is customized later by adding rules for `INSERT`, `UPDATE`, and `DELETE` operations so that the final result will be a view that behaves like a real table with some magic functionality. This is not such a simple example to start from and this makes things harder to get into. But it's better to have one example that covers all the points discussed step by step rather than having many different ones that might mix up in mind.

For the example, we need a little `min` function that returns the lower of 2 integer values. We create that as:

```
CREATE FUNCTION min(integer, integer) RETURNS integer AS $$
    SELECT CASE WHEN $1 < $2 THEN $1 ELSE $2 END
$$ LANGUAGE SQL STRICT;
```

The real tables we need in the first two rule system descriptions are these:

```
CREATE TABLE shoe_data (
    shoename    text,          -- primary key
    sh_avail    integer,       -- available number of pairs
    slcolor     text,          -- preferred shoelace color
    slminlen    real,          -- minimum shoelace length
    slmaxlen    real,          -- maximum shoelace length
    slunit      text           -- length unit
);

CREATE TABLE shoelace_data (
    sl_name     text,          -- primary key
    sl_avail    integer,       -- available number of pairs
    sl_color    text,          -- shoelace color
    sl_len      real,          -- shoelace length
    sl_unit     text           -- length unit
);

CREATE TABLE unit (
    un_name     text,          -- primary key
    un_fact     real           -- factor to transform to cm
);
```

As you can see, they represent shoe-store data.

The views are created as:

```
CREATE VIEW shoe AS
    SELECT sh.shoename,
           sh.sh_avail,
           sh.slcolor,
           sh.slminlen,
           sh.slminlen * un.un_fact AS slminlen_cm,
           sh.slmaxlen,
           sh.slmaxlen * un.un_fact AS slmaxlen_cm,
           sh.slunit
    FROM shoe_data sh, unit un
    WHERE sh.slunit = un.un_name;

CREATE VIEW shoelace AS
    SELECT s.sl_name,
           s.sl_avail,
           s.sl_color,
           s.sl_len,
           s.sl_unit,
           s.sl_len * u.un_fact AS sl_len_cm
    FROM shoelace_data s, unit u
    WHERE s.sl_unit = u.un_name;

CREATE VIEW shoe_ready AS
    SELECT rsh.shoename,
```

```

        rsh.sh_avail,
        rsl.sl_name,
        rsl.sl_avail,
        min(rsh.sh_avail, rsl.sl_avail) AS total_avail
FROM shoe rsh, shoelace rsl
WHERE rsl.sl_color = rsh.slcolor
      AND rsl.sl_len_cm >= rsh.slminlen_cm
      AND rsl.sl_len_cm <= rsh.slmaxlen_cm;

```

The `CREATE VIEW` command for the shoelace view (which is the simplest one we have) will create a relation `shoelace` and an entry in `pg_rewrite` that tells that there is a rewrite rule that must be applied whenever the relation `shoelace` is referenced in a query's range table. The rule has no rule qualification (discussed later, with the non-`SELECT` rules, since `SELECT` rules currently cannot have them) and it is `INSTEAD`. Note that rule qualifications are not the same as query qualifications. The action of our rule has a query qualification. The action of the rule is one query tree that is a copy of the `SELECT` statement in the view creation command.

**Note:** The two extra range table entries for `NEW` and `OLD` (named `*NEW*` and `*OLD*` for historical reasons in the printed query tree) you can see in the `pg_rewrite` entry aren't of interest for `SELECT` rules.

Now we populate `unit`, `shoe_data` and `shoelace_data` and run a simple query on a view:

```

INSERT INTO unit VALUES ('cm', 1.0);
INSERT INTO unit VALUES ('m', 100.0);
INSERT INTO unit VALUES ('inch', 2.54);

INSERT INTO shoe_data VALUES ('sh1', 2, 'black', 70.0, 90.0, 'cm');
INSERT INTO shoe_data VALUES ('sh2', 0, 'black', 30.0, 40.0, 'inch');
INSERT INTO shoe_data VALUES ('sh3', 4, 'brown', 50.0, 65.0, 'cm');
INSERT INTO shoe_data VALUES ('sh4', 3, 'brown', 40.0, 50.0, 'inch');

INSERT INTO shoelace_data VALUES ('sl1', 5, 'black', 80.0, 'cm');
INSERT INTO shoelace_data VALUES ('sl2', 6, 'black', 100.0, 'cm');
INSERT INTO shoelace_data VALUES ('sl3', 0, 'black', 35.0, 'inch');
INSERT INTO shoelace_data VALUES ('sl4', 8, 'black', 40.0, 'inch');
INSERT INTO shoelace_data VALUES ('sl5', 4, 'brown', 1.0, 'm');
INSERT INTO shoelace_data VALUES ('sl6', 0, 'brown', 0.9, 'm');
INSERT INTO shoelace_data VALUES ('sl7', 7, 'brown', 60, 'cm');
INSERT INTO shoelace_data VALUES ('sl8', 1, 'brown', 40, 'inch');

SELECT * FROM shoelace;

```

sl_name	sl_avail	sl_color	sl_len	sl_unit	sl_len_cm
sl1	5	black	80	cm	80
sl2	6	black	100	cm	100
sl7	7	brown	60	cm	60
sl3	0	black	35	inch	88.9
sl4	8	black	40	inch	101.6
sl8	1	brown	40	inch	101.6

sl5		4		brown		1		m		100
sl6		0		brown		0.9		m		90

(8 rows)

This is the simplest `SELECT` you can do on our views, so we take this opportunity to explain the basics of view rules. The `SELECT * FROM shoelace` was interpreted by the parser and produced the query tree:

```
SELECT shoelace.sl_name, shoelace.sl_avail,
       shoelace.sl_color, shoelace.sl_len,
       shoelace.sl_unit, shoelace.sl_len_cm
FROM shoelace shoelace;
```

and this is given to the rule system. The rule system walks through the range table and checks if there are rules for any relation. When processing the range table entry for `shoelace` (the only one up to now) it finds the `_RETURN` rule with the query tree:

```
SELECT s.sl_name, s.sl_avail,
       s.sl_color, s.sl_len, s.sl_unit,
       s.sl_len * u.un_fact AS sl_len_cm
FROM shoelace *OLD*, shoelace *NEW*,
     shoelace_data s, unit u
WHERE s.sl_unit = u.un_name;
```

To expand the view, the rewriter simply creates a subquery range-table entry containing the rule's action query tree, and substitutes this range table entry for the original one that referenced the view. The resulting rewritten query tree is almost the same as if you had typed:

```
SELECT shoelace.sl_name, shoelace.sl_avail,
       shoelace.sl_color, shoelace.sl_len,
       shoelace.sl_unit, shoelace.sl_len_cm
FROM (SELECT s.sl_name,
            s.sl_avail,
            s.sl_color,
            s.sl_len,
            s.sl_unit,
            s.sl_len * u.un_fact AS sl_len_cm
      FROM shoelace_data s, unit u
      WHERE s.sl_unit = u.un_name) shoelace;
```

There is one difference however: the subquery's range table has two extra entries `shoelace *OLD*` and `shoelace *NEW*`. These entries don't participate directly in the query, since they aren't referenced by the subquery's join tree or target list. The rewriter uses them to store the access privilege check information that was originally present in the range-table entry that referenced the view. In this way, the executor will still check that the user has proper privileges to access the view, even though there's no direct use of the view in the rewritten query.

That was the first rule applied. The rule system will continue checking the remaining range-table entries in the top query (in this example there are no more), and it will recursively check the range-table entries in the added subquery to see if any of them reference views. (But it won't expand `*OLD*` or `*NEW*` —

otherwise we'd have infinite recursion!) In this example, there are no rewrite rules for `shoelace_data` or `unit`, so rewriting is complete and the above is the final result given to the planner.

Now we want to write a query that finds out for which shoes currently in the store we have the matching shoelaces (color and length) and where the total number of exactly matching pairs is greater or equal to two.

```
SELECT * FROM shoe_ready WHERE total_avail >= 2;
```

shoename	sh_avail	sl_name	sl_avail	total_avail
sh1	2	sl1	5	2
sh3	4	sl7	7	4

(2 rows)

The output of the parser this time is the query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM shoe_ready shoe_ready
WHERE shoe_ready.total_avail >= 2;
```

The first rule applied will be the one for the `shoe_ready` view and it results in the query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM (SELECT rsh.shoename,
            rsh.sh_avail,
            rsl.sl_name,
            rsl.sl_avail,
            min(rsh.sh_avail, rsl.sl_avail) AS total_avail
      FROM shoe rsh, shoelace rsl
      WHERE rsl.sl_color = rsh.slcolor
            AND rsl.sl_len_cm >= rsh.slminlen_cm
            AND rsl.sl_len_cm <= rsh.slmaxlen_cm) shoe_ready
WHERE shoe_ready.total_avail >= 2;
```

Similarly, the rules for `shoe` and `shoelace` are substituted into the range table of the subquery, leading to a three-level final query tree:

```
SELECT shoe_ready.shoename, shoe_ready.sh_avail,
       shoe_ready.sl_name, shoe_ready.sl_avail,
       shoe_ready.total_avail
FROM (SELECT rsh.shoename,
            rsh.sh_avail,
            rsl.sl_name,
            rsl.sl_avail,
            min(rsh.sh_avail, rsl.sl_avail) AS total_avail
      FROM (SELECT sh.shoename,
                  sh.sh_avail,
                  sl.sl_name,
                  sl.sl_avail,
                  min(sl.sl_avail, sh.sh_avail) AS total_avail
            FROM shoelace sl, shoe sh
            WHERE sl.sl_color = sh.slcolor
                  AND sl.sl_len_cm >= sh.slminlen_cm
                  AND sl.sl_len_cm <= sh.slmaxlen_cm) shoe_ready
      WHERE shoe_ready.total_avail >= 2;
```

```

        sh.slcolor,
        sh.slminlen,
        sh.slminlen * un.un_fact AS slminlen_cm,
        sh.slmaxlen,
        sh.slmaxlen * un.un_fact AS slmaxlen_cm,
        sh.slunit
    FROM shoe_data sh, unit un
    WHERE sh.slunit = un.un_name) rsh,
    (SELECT s.sl_name,
        s.sl_avail,
        s.sl_color,
        s.sl_len,
        s.sl_unit,
        s.sl_len * u.un_fact AS sl_len_cm
    FROM shoelace_data s, unit u
    WHERE s.sl_unit = u.un_name) rsl
    WHERE rsl.sl_color = rsh.slcolor
        AND rsl.sl_len_cm >= rsh.slminlen_cm
        AND rsl.sl_len_cm <= rsh.slmaxlen_cm) shoe_ready
    WHERE shoe_ready.total_avail > 2;

```

It turns out that the planner will collapse this tree into a two-level query tree: the bottommost `SELECT` commands will be “pulled up” into the middle `SELECT` since there’s no need to process them separately. But the middle `SELECT` will remain separate from the top, because it contains aggregate functions. If we pulled those up it would change the behavior of the topmost `SELECT`, which we don’t want. However, collapsing the query tree is an optimization that the rewrite system doesn’t have to concern itself with.

### 36.2.2. View Rules in Non-`SELECT` Statements

Two details of the query tree aren’t touched in the description of view rules above. These are the command type and the result relation. In fact, view rules don’t need this information.

There are only a few differences between a query tree for a `SELECT` and one for any other command. Obviously, they have a different command type and for a command other than a `SELECT`, the result relation points to the range-table entry where the result should go. Everything else is absolutely the same. So having two tables `t1` and `t2` with columns `a` and `b`, the query trees for the two statements:

```
SELECT t2.b FROM t1, t2 WHERE t1.a = t2.a;
```

```
UPDATE t1 SET b = t2.b FROM t2 WHERE t1.a = t2.a;
```

are nearly identical. In particular:

- The range tables contain entries for the tables `t1` and `t2`.
- The target lists contain one variable that points to column `b` of the range table entry for table `t2`.
- The qualification expressions compare the columns `a` of both range-table entries for equality.

- The join trees show a simple join between `t1` and `t2`.

The consequence is, that both query trees result in similar execution plans: They are both joins over the two tables. For the `UPDATE` the missing columns from `t1` are added to the target list by the planner and the final query tree will read as:

```
UPDATE t1 SET a = t1.a, b = t2.b FROM t2 WHERE t1.a = t2.a;
```

and thus the executor run over the join will produce exactly the same result set as a:

```
SELECT t1.a, t2.b FROM t1, t2 WHERE t1.a = t2.a;
```

will do. But there is a little problem in `UPDATE`: The executor does not care what the results from the join it is doing are meant for. It just produces a result set of rows. The difference that one is a `SELECT` command and the other is an `UPDATE` is handled in the caller of the executor. The caller still knows (looking at the query tree) that this is an `UPDATE`, and it knows that this result should go into table `t1`. But which of the rows that are there has to be replaced by the new row?

To resolve this problem, another entry is added to the target list in `UPDATE` (and also in `DELETE`) statements: the current tuple ID (CTID). This is a system column containing the file block number and position in the block for the row. Knowing the table, the CTID can be used to retrieve the original row of `t1` to be updated. After adding the CTID to the target list, the query actually looks like:

```
SELECT t1.a, t2.b, t1.ctid FROM t1, t2 WHERE t1.a = t2.a;
```

Now another detail of PostgreSQL enters the stage. Old table rows aren't overwritten, and this is why `ROLLBACK` is fast. In an `UPDATE`, the new result row is inserted into the table (after stripping the CTID) and in the row header of the old row, which the CTID pointed to, the `ctmax` and `ctxid` entries are set to the current command counter and current transaction ID. Thus the old row is hidden, and after the transaction commits the vacuum cleaner can really remove it.

Knowing all that, we can simply apply view rules in absolutely the same way to any command. There is no difference.

### 36.2.3. The Power of Views in PostgreSQL

The above demonstrates how the rule system incorporates view definitions into the original query tree. In the second example, a simple `SELECT` from one view created a final query tree that is a join of 4 tables (`unit` was used twice with different names).

The benefit of implementing views with the rule system is, that the planner has all the information about which tables have to be scanned plus the relationships between these tables plus the restrictive qualifications from the views plus the qualifications from the original query in one single query tree. And this is still the situation when the original query is already a join over views. The planner has to decide which is the best path to execute the query, and the more information the planner has, the better this decision can be. And the rule system as implemented in PostgreSQL ensures, that this is all information available about the query up to that point.

### 36.2.4. Updating a View

What happens if a view is named as the target relation for an `INSERT`, `UPDATE`, or `DELETE`? After doing the substitutions described above, we will have a query tree in which the result relation points at a subquery range-table entry. This will not work, so the rewriter throws an error if it sees it has produced such a thing.

To change this, we can define rules that modify the behavior of these kinds of commands. This is the topic of the next section.

## 36.3. Rules on `INSERT`, `UPDATE`, and `DELETE`

Rules that are defined on `INSERT`, `UPDATE`, and `DELETE` are significantly different from the view rules described in the previous section. First, their `CREATE RULE` command allows more:

- They are allowed to have no action.
- They can have multiple actions.
- They can be `INSTEAD` or `ALSO` (the default).
- The pseudorelations `NEW` and `OLD` become useful.
- They can have rule qualifications.

Second, they don't modify the query tree in place. Instead they create zero or more new query trees and can throw away the original one.

### 36.3.1. How Update Rules Work

Keep the syntax:

```
CREATE [ OR REPLACE ] RULE name AS ON event
    TO table [ WHERE condition ]
    DO [ ALSO | INSTEAD ] { NOTHING | command | ( command ; command ... ) }
```

in mind. In the following, *update rules* means rules that are defined on `INSERT`, `UPDATE`, or `DELETE`.

Update rules get applied by the rule system when the result relation and the command type of a query tree are equal to the object and event given in the `CREATE RULE` command. For update rules, the rule system creates a list of query trees. Initially the query-tree list is empty. There can be zero (`NOTHING` key word), one, or multiple actions. To simplify, we will look at a rule with one action. This rule can have a qualification or not and it can be `INSTEAD` or `ALSO` (the default).

What is a rule qualification? It is a restriction that tells when the actions of the rule should be done and when not. This qualification can only reference the pseudorelations `NEW` and/or `OLD`, which basically represent the relation that was given as object (but with a special meaning).

So we have three cases that produce the following query trees for a one-action rule.

No qualification, with either `ALSO` or `INSTEAD`

the query tree from the rule action with the original query tree's qualification added

Qualification given and `ALSO`

the query tree from the rule action with the rule qualification and the original query tree's qualification added

Qualification given and `INSTEAD`

the query tree from the rule action with the rule qualification and the original query tree's qualification; and the original query tree with the negated rule qualification added

Finally, if the rule is `ALSO`, the unchanged original query tree is added to the list. Since only qualified `INSTEAD` rules already add the original query tree, we end up with either one or two output query trees for a rule with one action.

For `ON INSERT` rules, the original query (if not suppressed by `INSTEAD`) is done before any actions added by rules. This allows the actions to see the inserted row(s). But for `ON UPDATE` and `ON DELETE` rules, the original query is done after the actions added by rules. This ensures that the actions can see the to-be-updated or to-be-deleted rows; otherwise, the actions might do nothing because they find no rows matching their qualifications.

The query trees generated from rule actions are thrown into the rewrite system again, and maybe more rules get applied resulting in more or less query trees. So a rule's actions must have either a different command type or a different result relation than the rule itself is on, otherwise this recursive process will end up in an infinite loop. (Recursive expansion of a rule will be detected and reported as an error.)

The query trees found in the actions of the `pg_rewrite` system catalog are only templates. Since they can reference the range-table entries for `NEW` and `OLD`, some substitutions have to be made before they can be used. For any reference to `NEW`, the target list of the original query is searched for a corresponding entry. If found, that entry's expression replaces the reference. Otherwise, `NEW` means the same as `OLD` (for an `UPDATE`) or is replaced by a null value (for an `INSERT`). Any reference to `OLD` is replaced by a reference to the range-table entry that is the result relation.

After the system is done applying update rules, it applies view rules to the produced query tree(s). Views cannot insert new update actions so there is no need to apply update rules to the output of view rewriting.

### 36.3.1.1. A First Rule Step by Step

Say we want to trace changes to the `sl_avail` column in the `shoelace_data` relation. So we set up a log table and a rule that conditionally writes a log entry when an `UPDATE` is performed on `shoelace_data`.

```
CREATE TABLE shoelace_log (
    sl_name    text,          -- shoelace changed
    sl_avail   integer,       -- new available value
    log_who    text,          -- who did it
    log_when   timestamp      -- when
);

CREATE RULE log_shoelace AS ON UPDATE TO shoelace_data
    WHERE NEW.sl_avail <> OLD.sl_avail
    DO INSERT INTO shoelace_log VALUES (
        NEW.sl_name,
```

```

NEW.sl_avail,
current_user,
current_timestamp
);

```

Now someone does:

```
UPDATE shoelace_data SET sl_avail = 6 WHERE sl_name = 'sl7';
```

and we look at the log table:

```
SELECT * FROM shoelace_log;
```

```

sl_name | sl_avail | log_who | log_when
-----+-----+-----+-----
sl7      |        6 | Al      | Tue Oct 20 16:14:45 1998 MET DST
(1 row)

```

That's what we expected. What happened in the background is the following. The parser created the query tree:

```

UPDATE shoelace_data SET sl_avail = 6
  FROM shoelace_data shoelace_data
 WHERE shoelace_data.sl_name = 'sl7';

```

There is a rule `log_shoelace` that is ON UPDATE with the rule qualification expression:

```
NEW.sl_avail <> OLD.sl_avail
```

and the action:

```

INSERT INTO shoelace_log VALUES (
  *NEW*.sl_name, *NEW*.sl_avail,
  current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*;

```

(This looks a little strange since you cannot normally write `INSERT ... VALUES ... FROM`. The `FROM` clause here is just to indicate that there are range-table entries in the query tree for `*NEW*` and `*OLD*`. These are needed so that they can be referenced by variables in the `INSERT` command's query tree.)

The rule is a qualified `ALSO` rule, so the rule system has to return two query trees: the modified rule action and the original query tree. In step 1, the range table of the original query is incorporated into the rule's action query tree. This results in:

```

INSERT INTO shoelace_log VALUES (
  *NEW*.sl_name, *NEW*.sl_avail,
  current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
  shoelace_data shoelace_data;

```

In step 2, the rule qualification is added to it, so the result set is restricted to rows where `sl_avail` changes:

```
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE *NEW*.sl_avail <> *OLD*.sl_avail;
```

(This looks even stranger, since `INSERT ... VALUES` doesn't have a `WHERE` clause either, but the planner and executor will have no difficulty with it. They need to support this same functionality anyway for `INSERT ... SELECT`.)

In step 3, the original query tree's qualification is added, restricting the result set further to only the rows that would have been touched by the original query:

```
INSERT INTO shoelace_log VALUES (
    *NEW*.sl_name, *NEW*.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE *NEW*.sl_avail <> *OLD*.sl_avail
AND shoelace_data.sl_name = 'sl7';
```

Step 4 replaces references to `NEW` by the target list entries from the original query tree or by the matching variable references from the result relation:

```
INSERT INTO shoelace_log VALUES (
    shoelace_data.sl_name, 6,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE 6 <> *OLD*.sl_avail
AND shoelace_data.sl_name = 'sl7';
```

Step 5 changes `OLD` references into result relation references:

```
INSERT INTO shoelace_log VALUES (
    shoelace_data.sl_name, 6,
    current_user, current_timestamp )
FROM shoelace_data *NEW*, shoelace_data *OLD*,
    shoelace_data shoelace_data
WHERE 6 <> shoelace_data.sl_avail
AND shoelace_data.sl_name = 'sl7';
```

That's it. Since the rule is `ALSO`, we also output the original query tree. In short, the output from the rule system is a list of two query trees that correspond to these statements:

```

INSERT INTO shoelace_log VALUES (
    shoelace_data.sl_name, 6,
    current_user, current_timestamp )
FROM shoelace_data
WHERE 6 <> shoelace_data.sl_avail
    AND shoelace_data.sl_name = 'sl7';

UPDATE shoelace_data SET sl_avail = 6
WHERE sl_name = 'sl7';

```

These are executed in this order, and that is exactly what the rule was meant to do.

The substitutions and the added qualifications ensure that, if the original query would be, say:

```

UPDATE shoelace_data SET sl_color = 'green'
WHERE sl_name = 'sl7';

```

no log entry would get written. In that case, the original query tree does not contain a target list entry for `sl_avail`, so `NEW.sl_avail` will get replaced by `shoelace_data.sl_avail`. Thus, the extra command generated by the rule is:

```

INSERT INTO shoelace_log VALUES (
    shoelace_data.sl_name, shoelace_data.sl_avail,
    current_user, current_timestamp )
FROM shoelace_data
WHERE shoelace_data.sl_avail <> shoelace_data.sl_avail
    AND shoelace_data.sl_name = 'sl7';

```

and that qualification will never be true.

It will also work if the original query modifies multiple rows. So if someone issued the command:

```

UPDATE shoelace_data SET sl_avail = 0
WHERE sl_color = 'black';

```

four rows in fact get updated (`sl1`, `sl2`, `sl3`, and `sl4`). But `sl3` already has `sl_avail = 0`. In this case, the original query tree's qualification is different and that results in the extra query tree:

```

INSERT INTO shoelace_log
SELECT shoelace_data.sl_name, 0,
    current_user, current_timestamp
FROM shoelace_data
WHERE 0 <> shoelace_data.sl_avail
    AND shoelace_data.sl_color = 'black';

```

being generated by the rule. This query tree will surely insert three new log entries. And that's absolutely correct.

Here we can see why it is important that the original query tree is executed last. If the `UPDATE` had been executed first, all the rows would have already been set to zero, so the logging `INSERT` would not find any row where `0 <> shoelace_data.sl_avail`.

### 36.3.2. Cooperation with Views

A simple way to protect view relations from the mentioned possibility that someone can try to run `INSERT`, `UPDATE`, or `DELETE` on them is to let those query trees get thrown away. So we could create the rules:

```
CREATE RULE shoe_ins_protect AS ON INSERT TO shoe
DO INSTEAD NOTHING;
CREATE RULE shoe_upd_protect AS ON UPDATE TO shoe
DO INSTEAD NOTHING;
CREATE RULE shoe_del_protect AS ON DELETE TO shoe
DO INSTEAD NOTHING;
```

If someone now tries to do any of these operations on the view relation `shoe`, the rule system will apply these rules. Since the rules have no actions and are `INSTEAD`, the resulting list of query trees will be empty and the whole query will become nothing because there is nothing left to be optimized or executed after the rule system is done with it.

A more sophisticated way to use the rule system is to create rules that rewrite the query tree into one that does the right operation on the real tables. To do that on the `shoelace` view, we create the following rules:

```
CREATE RULE shoelace_ins AS ON INSERT TO shoelace
DO INSTEAD
INSERT INTO shoelace_data VALUES (
    NEW.sl_name,
    NEW.sl_avail,
    NEW.sl_color,
    NEW.sl_len,
    NEW.sl_unit
);

CREATE RULE shoelace_upd AS ON UPDATE TO shoelace
DO INSTEAD
UPDATE shoelace_data
SET sl_name = NEW.sl_name,
    sl_avail = NEW.sl_avail,
    sl_color = NEW.sl_color,
    sl_len = NEW.sl_len,
    sl_unit = NEW.sl_unit
WHERE sl_name = OLD.sl_name;

CREATE RULE shoelace_del AS ON DELETE TO shoelace
DO INSTEAD
DELETE FROM shoelace_data
WHERE sl_name = OLD.sl_name;
```

If you want to support `RETURNING` queries on the view, you need to make the rules include `RETURNING` clauses that compute the view rows. This is usually pretty trivial for views on a single table, but it's a bit tedious for join views such as `shoelace`. An example for the insert case is:

```
CREATE RULE shoelace_ins AS ON INSERT TO shoelace
DO INSTEAD
```

```

INSERT INTO shoelace_data VALUES (
    NEW.sl_name,
    NEW.sl_avail,
    NEW.sl_color,
    NEW.sl_len,
    NEW.sl_unit
)
RETURNING
    shoelace_data.*,
    (SELECT shoelace_data.sl_len * u.un_fact
     FROM unit u WHERE shoelace_data.sl_unit = u.un_name);

```

Note that this one rule supports both `INSERT` and `INSERT RETURNING` queries on the view — the `RETURNING` clause is simply ignored for `INSERT`.

Now assume that once in a while, a pack of shoelaces arrives at the shop and a big parts list along with it. But you don't want to manually update the `shoelace` view every time. Instead we setup two little tables: one where you can insert the items from the part list, and one with a special trick. The creation commands for these are:

```

CREATE TABLE shoelace_arrive (
    arr_name    text,
    arr_quant   integer
);

CREATE TABLE shoelace_ok (
    ok_name     text,
    ok_quant    integer
);

CREATE RULE shoelace_ok_ins AS ON INSERT TO shoelace_ok
DO INSTEAD
UPDATE shoelace
    SET sl_avail = sl_avail + NEW.ok_quant
    WHERE sl_name = NEW.ok_name;

```

Now you can fill the table `shoelace_arrive` with the data from the parts list:

```
SELECT * FROM shoelace_arrive;
```

```

arr_name | arr_quant
-----+-----
sl3      |         10
sl6      |         20
sl8      |         20
(3 rows)

```

Take a quick look at the current data:

```
SELECT * FROM shoelace;
```

```

sl_name | sl_avail | sl_color | sl_len | sl_unit | sl_len_cm
-----+-----+-----+-----+-----+-----
sl1     |         5 | black   |      80 | cm      |         80

```

```

sl2      |          6 | black   |      100 | cm      |      100
sl7      |          6 | brown   |       60 | cm      |       60
sl3      |          0 | black   |       35 | inch    |      88.9
sl4      |          8 | black   |       40 | inch    |     101.6
sl8      |          1 | brown   |       40 | inch    |     101.6
sl5      |          4 | brown   |        1 | m       |      100
sl6      |          0 | brown   |       0.9 | m       |       90
(8 rows)

```

Now move the arrived shoelaces in:

```
INSERT INTO shoelace_ok SELECT * FROM shoelace_arrive;
```

and check the results:

```
SELECT * FROM shoelace ORDER BY sl_name;
```

```

sl_name | sl_avail | sl_color | sl_len | sl_unit | sl_len_cm
-----+-----+-----+-----+-----+-----
sl1     |         5 | black   |      80 | cm      |      80
sl2     |         6 | black   |     100 | cm      |     100
sl7     |         6 | brown   |      60 | cm      |      60
sl4     |         8 | black   |      40 | inch    |     101.6
sl3     |        10 | black   |      35 | inch    |      88.9
sl8     |        21 | brown   |      40 | inch    |     101.6
sl5     |         4 | brown   |        1 | m       |      100
sl6     |        20 | brown   |       0.9 | m       |       90
(8 rows)

```

```
SELECT * FROM shoelace_log;
```

```

sl_name | sl_avail | log_who | log_when
-----+-----+-----+-----
sl7     |         6 | A1      | Tue Oct 20 19:14:45 1998 MET DST
sl3     |        10 | A1      | Tue Oct 20 19:25:16 1998 MET DST
sl6     |        20 | A1      | Tue Oct 20 19:25:16 1998 MET DST
sl8     |        21 | A1      | Tue Oct 20 19:25:16 1998 MET DST
(4 rows)

```

It's a long way from the one `INSERT ... SELECT` to these results. And the description of the query-tree transformation will be the last in this chapter. First, there is the parser's output:

```

INSERT INTO shoelace_ok
SELECT shoelace_arrive.arr_name, shoelace_arrive.arr_quant
FROM shoelace_arrive shoelace_arrive, shoelace_ok shoelace_ok;

```

Now the first rule `shoelace_ok_ins` is applied and turns this into:

```

UPDATE shoelace
SET sl_avail = shoelace.sl_avail + shoelace_arrive.arr_quant
FROM shoelace_arrive shoelace_arrive, shoelace_ok shoelace_ok,
shoelace_ok *OLD*, shoelace_ok *NEW*,

```

```

        shoelace shoelace
WHERE shoelace.sl_name = shoelace_arrive.arr_name;

```

and throws away the original INSERT on shoelace\_ok. This rewritten query is passed to the rule system again, and the second applied rule shoelace\_upd produces:

```

UPDATE shoelace_data
  SET sl_name = shoelace.sl_name,
      sl_avail = shoelace.sl_avail + shoelace_arrive.arr_quant,
      sl_color = shoelace.sl_color,
      sl_len = shoelace.sl_len,
      sl_unit = shoelace.sl_unit
FROM shoelace_arrive shoelace_arrive, shoelace_ok shoelace_ok,
      shoelace_ok *OLD*, shoelace_ok *NEW*,
      shoelace shoelace, shoelace *OLD*,
      shoelace *NEW*, shoelace_data shoelace_data
WHERE shoelace.sl_name = shoelace_arrive.arr_name
      AND shoelace_data.sl_name = shoelace.sl_name;

```

Again it's an INSTEAD rule and the previous query tree is trashed. Note that this query still uses the view shoelace. But the rule system isn't finished with this step, so it continues and applies the \_RETURN rule on it, and we get:

```

UPDATE shoelace_data
  SET sl_name = s.sl_name,
      sl_avail = s.sl_avail + shoelace_arrive.arr_quant,
      sl_color = s.sl_color,
      sl_len = s.sl_len,
      sl_unit = s.sl_unit
FROM shoelace_arrive shoelace_arrive, shoelace_ok shoelace_ok,
      shoelace_ok *OLD*, shoelace_ok *NEW*,
      shoelace shoelace, shoelace *OLD*,
      shoelace *NEW*, shoelace_data shoelace_data,
      shoelace *OLD*, shoelace *NEW*,
      shoelace_data s, unit u
WHERE s.sl_name = shoelace_arrive.arr_name
      AND shoelace_data.sl_name = s.sl_name;

```

Finally, the rule log\_shoelace gets applied, producing the extra query tree:

```

INSERT INTO shoelace_log
SELECT s.sl_name,
      s.sl_avail + shoelace_arrive.arr_quant,
      current_user,
      current_timestamp
FROM shoelace_arrive shoelace_arrive, shoelace_ok shoelace_ok,
      shoelace_ok *OLD*, shoelace_ok *NEW*,
      shoelace shoelace, shoelace *OLD*,
      shoelace *NEW*, shoelace_data shoelace_data,
      shoelace *OLD*, shoelace *NEW*,
      shoelace_data s, unit u,
      shoelace_data *OLD*, shoelace_data *NEW*
      shoelace_log shoelace_log

```

```

WHERE s.sl_name = shoelace_arrive.arr_name
      AND shoelace_data.sl_name = s.sl_name
      AND (s.sl_avail + shoelace_arrive.arr_quant) <> s.sl_avail;

```

After that the rule system runs out of rules and returns the generated query trees.

So we end up with two final query trees that are equivalent to the SQL statements:

```

INSERT INTO shoelace_log
SELECT s.sl_name,
       s.sl_avail + shoelace_arrive.arr_quant,
       current_user,
       current_timestamp
FROM shoelace_arrive shoelace_arrive, shoelace_data shoelace_data,
     shoelace_data s
WHERE s.sl_name = shoelace_arrive.arr_name
      AND shoelace_data.sl_name = s.sl_name
      AND s.sl_avail + shoelace_arrive.arr_quant <> s.sl_avail;

UPDATE shoelace_data
SET sl_avail = shoelace_data.sl_avail + shoelace_arrive.arr_quant
FROM shoelace_arrive shoelace_arrive,
     shoelace_data shoelace_data,
     shoelace_data s
WHERE s.sl_name = shoelace_arrive.sl_name
      AND shoelace_data.sl_name = s.sl_name;

```

The result is that data coming from one relation inserted into another, changed into updates on a third, changed into updating a fourth plus logging that final update in a fifth gets reduced into two queries.

There is a little detail that's a bit ugly. Looking at the two queries, it turns out that the `shoelace_data` relation appears twice in the range table where it could definitely be reduced to one. The planner does not handle it and so the execution plan for the rule systems output of the `INSERT` will be

```

Nested Loop
-> Merge Join
    -> Seq Scan
        -> Sort
            -> Seq Scan on s
    -> Seq Scan
        -> Sort
            -> Seq Scan on shoelace_arrive
-> Seq Scan on shoelace_data

```

while omitting the extra range table entry would result in a

```

Merge Join
-> Seq Scan
    -> Sort
        -> Seq Scan on s
-> Seq Scan
    -> Sort
        -> Seq Scan on shoelace_arrive

```

which produces exactly the same entries in the log table. Thus, the rule system caused one extra scan on the table `shoelace_data` that is absolutely not necessary. And the same redundant scan is done once more in the `UPDATE`. But it was a really hard job to make that all possible at all.

Now we make a final demonstration of the PostgreSQL rule system and its power. Say you add some shoelaces with extraordinary colors to your database:

```
INSERT INTO shoelace VALUES ('sl9', 0, 'pink', 35.0, 'inch', 0.0);
INSERT INTO shoelace VALUES ('sl10', 1000, 'magenta', 40.0, 'inch', 0.0);
```

We would like to make a view to check which `shoelace` entries do not fit any shoe in color. The view for this is:

```
CREATE VIEW shoelace_mismatch AS
  SELECT * FROM shoelace WHERE NOT EXISTS
    (SELECT shoename FROM shoe WHERE slcolor = sl_color);
```

Its output is:

```
SELECT * FROM shoelace_mismatch;
```

sl_name	sl_avail	sl_color	sl_len	sl_unit	sl_len_cm
sl9	0	pink	35	inch	88.9
sl10	1000	magenta	40	inch	101.6

Now we want to set it up so that mismatching shoelaces that are not in stock are deleted from the database. To make it a little harder for PostgreSQL, we don't delete it directly. Instead we create one more view:

```
CREATE VIEW shoelace_can_delete AS
  SELECT * FROM shoelace_mismatch WHERE sl_avail = 0;
```

and do it this way:

```
DELETE FROM shoelace WHERE EXISTS
  (SELECT * FROM shoelace_can_delete
    WHERE sl_name = shoelace.sl_name);
```

*Voilà:*

```
SELECT * FROM shoelace;
```

sl_name	sl_avail	sl_color	sl_len	sl_unit	sl_len_cm
sl1	5	black	80	cm	80
sl2	6	black	100	cm	100
sl7	6	brown	60	cm	60
sl4	8	black	40	inch	101.6
sl3	10	black	35	inch	88.9
sl8	21	brown	40	inch	101.6
sl10	1000	magenta	40	inch	101.6
sl5	4	brown	1	m	100

```

sl6      |      20 | brown      |      0.9 | m      |      90
(9 rows)

```

A `DELETE` on a view, with a subquery qualification that in total uses 4 nesting/joined views, where one of them itself has a subquery qualification containing a view and where calculated view columns are used, gets rewritten into one single query tree that deletes the requested data from a real table.

There are probably only a few situations out in the real world where such a construct is necessary. But it makes you feel comfortable that it works.

## 36.4. Rules and Privileges

Due to rewriting of queries by the PostgreSQL rule system, other tables/views than those used in the original query get accessed. When update rules are used, this can include write access to tables.

Rewrite rules don't have a separate owner. The owner of a relation (table or view) is automatically the owner of the rewrite rules that are defined for it. The PostgreSQL rule system changes the behavior of the default access control system. Relations that are used due to rules get checked against the privileges of the rule owner, not the user invoking the rule. This means that a user only needs the required privileges for the tables/views that he names explicitly in his queries.

For example: A user has a list of phone numbers where some of them are private, the others are of interest for the secretary of the office. He can construct the following:

```

CREATE TABLE phone_data (person text, phone text, private boolean);
CREATE VIEW phone_number AS
    SELECT person, phone FROM phone_data WHERE NOT private;
GRANT SELECT ON phone_number TO secretary;

```

Nobody except him (and the database superusers) can access the `phone_data` table. But because of the `GRANT`, the secretary can run a `SELECT` on the `phone_number` view. The rule system will rewrite the `SELECT` from `phone_number` into a `SELECT` from `phone_data` and add the qualification that only entries where `private` is false are wanted. Since the user is the owner of `phone_number` and therefore the owner of the rule, the read access to `phone_data` is now checked against his privileges and the query is permitted. The check for accessing `phone_number` is also performed, but this is done against the invoking user, so nobody but the user and the secretary can use it.

The privileges are checked rule by rule. So the secretary is for now the only one who can see the public phone numbers. But the secretary can setup another view and grant access to that to the public. Then, anyone can see the `phone_number` data through the secretary's view. What the secretary cannot do is to create a view that directly accesses `phone_data`. (Actually he can, but it will not work since every access will be denied during the permission checks.) And as soon as the user will notice, that the secretary opened his `phone_number` view, he can revoke his access. Immediately, any access to the secretary's view would fail.

One might think that this rule-by-rule checking is a security hole, but in fact it isn't. But if it did not work this way, the secretary could set up a table with the same columns as `phone_number` and copy the data to there once per day. Then it's his own data and he can grant access to everyone he wants. A `GRANT`

command means, “I trust you”. If someone you trust does the thing above, it’s time to think it over and then use `REVOKE`.

This mechanism also works for update rules. In the examples of the previous section, the owner of the tables in the example database could grant the privileges `SELECT`, `INSERT`, `UPDATE`, and `DELETE` on the `shoelace` view to someone else, but only `SELECT` on `shoelace_log`. The rule action to write log entries will still be executed successfully, and that other user could see the log entries. But he cannot create fake entries, nor could he manipulate or remove existing ones.

## 36.5. Rules and Command Status

The PostgreSQL server returns a command status string, such as `INSERT 149592 1`, for each command it receives. This is simple enough when there are no rules involved, but what happens when the query is rewritten by rules?

Rules affect the command status as follows:

- If there is no unconditional `INSTEAD` rule for the query, then the originally given query will be executed, and its command status will be returned as usual. (But note that if there were any conditional `INSTEAD` rules, the negation of their qualifications will have been added to the original query. This might reduce the number of rows it processes, and if so the reported status will be affected.)
- If there is any unconditional `INSTEAD` rule for the query, then the original query will not be executed at all. In this case, the server will return the command status for the last query that was inserted by an `INSTEAD` rule (conditional or unconditional) and is of the same command type (`INSERT`, `UPDATE`, or `DELETE`) as the original query. If no query meeting those requirements is added by any rule, then the returned command status shows the original query type and zeroes for the row-count and OID fields.

(This system was established in PostgreSQL 7.3. In versions before that, the command status might show different results when rules exist.)

The programmer can ensure that any desired `INSTEAD` rule is the one that sets the command status in the second case, by giving it the alphabetically last rule name among the active rules, so that it gets applied last.

## 36.6. Rules versus Triggers

Many things that can be done using triggers can also be implemented using the PostgreSQL rule system. One of the things that cannot be implemented by rules are some kinds of constraints, especially foreign keys. It is possible to place a qualified rule that rewrites a command to `NOTHING` if the value of a column does not appear in another table. But then the data is silently thrown away and that’s not a good idea. If checks for valid values are required, and in the case of an invalid value an error message should be generated, it must be done by a trigger.

On the other hand, a trigger that is fired on `INSERT` on a view can do the same as a rule: put the data somewhere else and suppress the insert in the view. But it cannot do the same thing on `UPDATE` or `DELETE`, because there is no real data in the view relation that could be scanned, and thus the trigger would never get called. Only a rule will help.

For the things that can be implemented by both, which is best depends on the usage of the database. A trigger is fired for any affected row once. A rule manipulates the query or generates an additional query. So if many rows are affected in one statement, a rule issuing one extra command is likely to be faster than a trigger that is called for every single row and must execute its operations many times. However, the trigger approach is conceptually far simpler than the rule approach, and is easier for novices to get right.

Here we show an example of how the choice of rules versus triggers plays out in one situation. There are two tables:

```
CREATE TABLE computer (
    hostname      text,      -- indexed
    manufacturer  text      -- indexed
);

CREATE TABLE software (
    software      text,      -- indexed
    hostname      text      -- indexed
);
```

Both tables have many thousands of rows and the indexes on `hostname` are unique. The rule or trigger should implement a constraint that deletes rows from `software` that reference a deleted computer. The trigger would use this command:

```
DELETE FROM software WHERE hostname = $1;
```

Since the trigger is called for each individual row deleted from `computer`, it can prepare and save the plan for this command and pass the `hostname` value in the parameter. The rule would be written as:

```
CREATE RULE computer_del AS ON DELETE TO computer
DO DELETE FROM software WHERE hostname = OLD.hostname;
```

Now we look at different types of deletes. In the case of a:

```
DELETE FROM computer WHERE hostname = 'mypc.local.net';
```

the table `computer` is scanned by index (fast), and the command issued by the trigger would also use an index scan (also fast). The extra command from the rule would be:

```
DELETE FROM software WHERE computer.hostname = 'mypc.local.net'
AND software.hostname = computer.hostname;
```

Since there are appropriate indexes setup, the planner will create a plan of

```
Nestloop
->  Index Scan using comp_hostidx on computer
->  Index Scan using soft_hostidx on software
```

So there would be not that much difference in speed between the trigger and the rule implementation.

With the next delete we want to get rid of all the 2000 computers where the `hostname` starts with `old`. There are two possible commands to do that. One is:

```
DELETE FROM computer WHERE hostname >= 'old'
                        AND hostname < 'ole'
```

The command added by the rule will be:

```
DELETE FROM software WHERE computer.hostname >= 'old' AND computer.hostname < 'ole'
                        AND software.hostname = computer.hostname;
```

with the plan

```
Hash Join
-> Seq Scan on software
-> Hash
    -> Index Scan using comp_hostidx on computer
```

The other possible command is:

```
DELETE FROM computer WHERE hostname ~ '^old';
```

which results in the following executing plan for the command added by the rule:

```
Nestloop
-> Index Scan using comp_hostidx on computer
-> Index Scan using soft_hostidx on software
```

This shows, that the planner does not realize that the qualification for `hostname` in `computer` could also be used for an index scan on `software` when there are multiple qualification expressions combined with `AND`, which is what it does in the regular-expression version of the command. The trigger will get invoked once for each of the 2000 old computers that have to be deleted, and that will result in one index scan over `computer` and 2000 index scans over `software`. The rule implementation will do it with two commands that use indexes. And it depends on the overall size of the table `software` whether the rule will still be faster in the sequential scan situation. 2000 command executions from the trigger over the SPI manager take some time, even if all the index blocks will soon be in the cache.

The last command we look at is:

```
DELETE FROM computer WHERE manufacturer = 'bim';
```

Again this could result in many rows to be deleted from `computer`. So the trigger will again run many commands through the executor. The command generated by the rule will be:

```
DELETE FROM software WHERE computer.manufacturer = 'bim'
                        AND software.hostname = computer.hostname;
```

The plan for that command will again be the nested loop over two index scans, only using a different index on `computer`:

```
Nestloop
-> Index Scan using comp_manufidx on computer
-> Index Scan using soft_hostidx on software
```

In any of these cases, the extra commands from the rule system will be more or less independent from the number of affected rows in a command.

The summary is, rules will only be significantly slower than triggers if their actions result in large and badly qualified joins, a situation where the planner fails.

# Chapter 37. Procedural Languages

PostgreSQL allows user-defined functions to be written in other languages besides SQL and C. These other languages are generically called *procedural languages* (PLs). For a function written in a procedural language, the database server has no built-in knowledge about how to interpret the function's source text. Instead, the task is passed to a special handler that knows the details of the language. The handler could either do all the work of parsing, syntax analysis, execution, etc. itself, or it could serve as “glue” between PostgreSQL and an existing implementation of a programming language. The handler itself is a C language function compiled into a shared object and loaded on demand, just like any other C function.

There are currently four procedural languages available in the standard PostgreSQL distribution: PL/pgSQL (Chapter 38), PL/Tcl (Chapter 39), PL/Perl (Chapter 40), and PL/Python (Chapter 41). There are additional procedural languages available that are not included in the core distribution. Appendix G has information about finding them. In addition other languages can be defined by users; the basics of developing a new procedural language are covered in Chapter 48.

## 37.1. Installing Procedural Languages

A procedural language must be “installed” into each database where it is to be used. But procedural languages installed in the database `template1` are automatically available in all subsequently created databases, since their entries in `template1` will be copied by `CREATE DATABASE`. So the database administrator can decide which languages are available in which databases and can make some languages available by default if he chooses.

For the languages supplied with the standard distribution, it is only necessary to execute `CREATE LANGUAGE language_name` to install the language into the current database. Alternatively, the program `createlang` can be used to do this from the shell command line. For example, to install the language PL/pgSQL into the database `template1`, use:

```
createlang plpgsql template1
```

The manual procedure described below is only recommended for installing custom languages that `CREATE LANGUAGE` does not know about.

### Manual Procedural Language Installation

A procedural language is installed in a database in four steps, which must be carried out by a database superuser. (For languages known to `CREATE LANGUAGE`, the second and third steps can be omitted, because they will be carried out automatically if needed.)

1. The shared object for the language handler must be compiled and installed into an appropriate library directory. This works in the same way as building and installing modules with regular user-defined C functions does; see Section 34.9.6. Often, the language handler will depend on an external library that provides the actual programming language engine; if so, that must be installed as well.
2. The handler must be declared with the command

```
CREATE FUNCTION handler_function_name()  
    RETURNS language_handler  
    AS 'path-to-shared-object'
```

```
LANGUAGE C;
```

The special return type of `language_handler` tells the database system that this function does not return one of the defined SQL data types and is not directly usable in SQL statements.

3. Optionally, the language handler can provide a “validator” function that checks a function definition for correctness without actually executing it. The validator function is called by `CREATE FUNCTION` if it exists. If a validator function is provided by the handler, declare it with a command like

```
CREATE FUNCTION validator_function_name(oid)
    RETURNS void
    AS 'path-to-shared-object'
    LANGUAGE C;
```

4. The PL must be declared with the command

```
CREATE [TRUSTED] [PROCEDURAL] LANGUAGE language-name
    HANDLER handler_function_name
    [VALIDATOR validator_function_name] ;
```

The optional key word `TRUSTED` specifies that ordinary database users that have no superuser privileges should be allowed to use this language to create functions and trigger procedures. Since PL functions are executed inside the database server, the `TRUSTED` flag should only be given for languages that do not allow access to database server internals or the file system. The languages PL/pgSQL, PL/Tcl, and PL/Perl are considered trusted; the languages PL/TclU, PL/PerlU, and PL/PythonU are designed to provide unlimited functionality and should *not* be marked trusted.

Example 37-1 shows how the manual installation procedure would work with the language PL/pgSQL.

#### Example 37-1. Manual Installation of PL/pgSQL

The following command tells the database server where to find the shared object for the PL/pgSQL language’s call handler function.

```
CREATE FUNCTION plpgsql_call_handler() RETURNS language_handler AS
    '$libdir/plpgsql' LANGUAGE C;
```

PL/pgSQL has a validator function, so we declare that too:

```
CREATE FUNCTION plpgsql_validator(oid) RETURNS void AS
    '$libdir/plpgsql' LANGUAGE C;
```

The command:

```
CREATE TRUSTED PROCEDURAL LANGUAGE plpgsql
    HANDLER plpgsql_call_handler
    VALIDATOR plpgsql_validator;
```

then defines that the previously declared functions should be invoked for functions and trigger procedures where the language attribute is `plpgsql`.

In a default PostgreSQL installation, the handler for the PL/pgSQL language is built and installed into the “library” directory. If Tcl support is configured in, the handlers for PL/Tcl and PL/TclU are also built and installed in the same location. Likewise, the PL/Perl and PL/PerlU handlers are built and installed if Perl support is configured, and the PL/PythonU handler is installed if Python support is configured.

# Chapter 38. PL/pgSQL - SQL Procedural Language

## 38.1. Overview

PL/pgSQL is a loadable procedural language for the PostgreSQL database system. The design goals of PL/pgSQL were to create a loadable procedural language that

- can be used to create functions and trigger procedures,
- adds control structures to the SQL language,
- can perform complex computations,
- inherits all user-defined types, functions, and operators,
- can be defined to be trusted by the server,
- is easy to use.

Functions created with PL/pgSQL can be used anywhere that built-in functions could be used. For example, it is possible to create complex conditional computation functions and later use them to define operators or use them in index expressions.

### 38.1.1. Advantages of Using PL/pgSQL

SQL is the language PostgreSQL and most other relational databases use as query language. It's portable and easy to learn. But every SQL statement must be executed individually by the database server.

That means that your client application must send each query to the database server, wait for it to be processed, receive and process the results, do some computation, then send further queries to the server. All this incurs interprocess communication and will also incur network overhead if your client is on a different machine than the database server.

With PL/pgSQL you can group a block of computation and a series of queries *inside* the database server, thus having the power of a procedural language and the ease of use of SQL, but with considerable savings of client/server communication overhead.

- Extra round trips between client and server are eliminated
- Intermediate results that the client does not need do not have to be marshaled or transferred between server and client
- Multiple rounds of query parsing can be avoided

This can result in a considerable performance increase as compared to an application that does not use stored functions.

Also, with PL/pgSQL you can use all the data types, operators and functions of SQL.

### 38.1.2. Supported Argument and Result Data Types

Functions written in PL/pgSQL can accept as arguments any scalar or array data type supported by the server, and they can return a result of any of these types. They can also accept or return any composite type (row type) specified by name. It is also possible to declare a PL/pgSQL function as returning `record`, which means that the result is a row type whose columns are determined by specification in the calling query, as discussed in Section 7.2.1.4.

PL/pgSQL functions can also be declared to accept and return the polymorphic types `anyelement`, `anyarray`, `anynonarray`, and `anyenum`. The actual data types handled by a polymorphic function can vary from call to call, as discussed in Section 34.2.5. An example is shown in Section 38.3.1.

PL/pgSQL functions can also be declared to return a “set” (or table) of any data type that can be returned as a single instance. Such a function generates its output by executing `RETURN NEXT` for each desired element of the result set, or by using `RETURN QUERY` to output the result of evaluating a query.

Finally, a PL/pgSQL function can be declared to return `void` if it has no useful return value.

PL/pgSQL functions can also be declared with output parameters in place of an explicit specification of the return type. This does not add any fundamental capability to the language, but it is often convenient, especially for returning multiple values.

Specific examples appear in Section 38.3.1 and Section 38.6.1.

## 38.2. Structure of PL/pgSQL

PL/pgSQL is a block-structured language. The complete text of a function definition must be a *block*. A block is defined as:

```
[ <<label>> ]
[ DECLARE
    declarations ]
BEGIN
    statements
END [ label ];
```

Each declaration and each statement within a block is terminated by a semicolon. A block that appears within another block must have a semicolon after `END`, as shown above; however the final `END` that concludes a function body does not require a semicolon.

**Tip:** A common mistake is to write a semicolon immediately after `BEGIN`. This is incorrect and will result in a syntax error.

A *label* is only needed if you want to identify the block for use in an `EXIT` statement, or to qualify the names of the variables declared in the block. If a label is given after `END`, it must match the label at the block’s beginning.

All key words are case-insensitive. Identifiers are implicitly converted to lowercase unless double-quoted, just as they are in ordinary SQL commands.

There are two types of comments in PL/pgSQL. A double dash (--) starts a comment that extends to the end of the line. A /\* starts a block comment that extends to the next occurrence of \*/. Block comments cannot be nested, but double dash comments can be enclosed into a block comment and a double dash can hide the block comment delimiters /\* and \*/.

Any statement in the statement section of a block can be a *subblock*. Subblocks can be used for logical grouping or to localize variables to a small group of statements. Variables declared in a subblock mask any similarly-named variables of outer blocks for the duration of the subblock; but you can access the outer variables anyway if you qualify their names with their block's label. For example:

```
CREATE FUNCTION somefunc() RETURNS integer AS $$
<< outerblock >>
DECLARE
    quantity integer := 30;
BEGIN
    RAISE NOTICE 'Quantity here is %', quantity; -- Prints 30
    quantity := 50;
    --
    -- Create a subblock
    --
    DECLARE
        quantity integer := 80;
    BEGIN
        RAISE NOTICE 'Quantity here is %', quantity; -- Prints 80
        RAISE NOTICE 'Outer quantity here is %', outerblock.quantity; -- Prints 50
    END;

    RAISE NOTICE 'Quantity here is %', quantity; -- Prints 50

    RETURN quantity;
END;
$$ LANGUAGE plpgsql;
```

**Note:** There is actually a hidden “outer block” surrounding the body of any PL/pgSQL function. This block provides the declarations of the function's parameters (if any), as well as some special variables such as `FOUND` (see Section 38.5.5). The outer block is labeled with the function's name, meaning that parameters and special variables can be qualified with the function's name.

It is important not to confuse the use of `BEGIN/END` for grouping statements in PL/pgSQL with the similarly-named SQL commands for transaction control. PL/pgSQL's `BEGIN/END` are only for grouping; they do not start or end a transaction. Functions and trigger procedures are always executed within a transaction established by an outer query — they cannot start or commit that transaction, since there would be no context for them to execute in. However, a block containing an `EXCEPTION` clause effectively forms a subtransaction that can be rolled back without affecting the outer transaction. For more about that see Section 38.6.5.

## 38.3. Declarations

All variables used in a block must be declared in the declarations section of the block. (The only exception is that the loop variable of a `FOR` loop iterating over a range of integer values is automatically declared as an integer variable.)

PL/pgSQL variables can have any SQL data type, such as `integer`, `varchar`, and `char`.

Here are some examples of variable declarations:

```
user_id integer;
quantity numeric(5);
url varchar;
myrow tablename%ROWTYPE;
myfield tablename.columnname%TYPE;
arow RECORD;
```

The general syntax of a variable declaration is:

```
name [ CONSTANT ] type [ NOT NULL ] [ { DEFAULT | := } expression ] ;
```

The `DEFAULT` clause, if given, specifies the initial value assigned to the variable when the block is entered. If the `DEFAULT` clause is not given then the variable is initialized to the SQL null value. The `CONSTANT` option prevents the variable from being assigned to, so that its value remains constant for the duration of the block. If `NOT NULL` is specified, an assignment of a null value results in a run-time error. All variables declared as `NOT NULL` must have a nonnull default value specified.

A variable's default value is evaluated and assigned to the variable each time the block is entered (not just once per function call). So, for example, assigning `now()` to a variable of type `timestamp` causes the variable to have the time of the current function call, not the time when the function was precompiled.

Examples:

```
quantity integer DEFAULT 32;
url varchar := 'http://mysite.com';
user_id CONSTANT integer := 10;
```

### 38.3.1. Aliases for Function Parameters

Parameters passed to functions are named with the identifiers `$1`, `$2`, etc. Optionally, aliases can be declared for `$n` parameter names for increased readability. Either the alias or the numeric identifier can then be used to refer to the parameter value.

There are two ways to create an alias. The preferred way is to give a name to the parameter in the `CREATE FUNCTION` command, for example:

```
CREATE FUNCTION sales_tax(subtotal real) RETURNS real AS $$
BEGIN
    RETURN subtotal * 0.06;
END;
```

```
$$ LANGUAGE plpgsql;
```

The other way, which was the only way available before PostgreSQL 8.0, is to explicitly declare an alias, using the declaration syntax

```
name ALIAS FOR $n;
```

The same example in this style looks like:

```
CREATE FUNCTION sales_tax(real) RETURNS real AS $$
DECLARE
    subtotal ALIAS FOR $1;
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

**Note:** These two examples are not perfectly equivalent. In the first case, `subtotal` could be referenced as `sales_tax.subtotal`, but in the second case it could not. (Had we attached a label to the block, `subtotal` could be qualified with that label, instead.)

Some more examples:

```
CREATE FUNCTION instr(vchar, integer) RETURNS integer AS $$
DECLARE
    v_string ALIAS FOR $1;
    index ALIAS FOR $2;
BEGIN
    -- some computations using v_string and index here
END;
$$ LANGUAGE plpgsql;
```

```
CREATE FUNCTION concat_selected_fields(in_t sometablename) RETURNS text AS $$
BEGIN
    RETURN in_t.f1 || in_t.f3 || in_t.f5 || in_t.f7;
END;
$$ LANGUAGE plpgsql;
```

When a PL/pgSQL function is declared with output parameters, the output parameters are given  $\$n$  names and optional aliases in just the same way as the normal input parameters. An output parameter is effectively a variable that starts out NULL; it should be assigned to during the execution of the function. The final value of the parameter is what is returned. For instance, the sales-tax example could also be done this way:

```
CREATE FUNCTION sales_tax(subtotal real, OUT tax real) AS $$
BEGIN
    tax := subtotal * 0.06;
```

```
END;
$$ LANGUAGE plpgsql;
```

Notice that we omitted `RETURNS real` — we could have included it, but it would be redundant.

Output parameters are most useful when returning multiple values. A trivial example is:

```
CREATE FUNCTION sum_n_product(x int, y int, OUT sum int, OUT prod int) AS $$
BEGIN
    sum := x + y;
    prod := x * y;
END;
$$ LANGUAGE plpgsql;
```

As discussed in Section 34.4.3, this effectively creates an anonymous record type for the function's results. If a `RETURNS` clause is given, it must say `RETURNS record`.

When the return type of a PL/pgSQL function is declared as a polymorphic type (`anyelement`, `anyarray`, `anynonarray`, or `anyenum`), a special parameter `$0` is created. Its data type is the actual return type of the function, as deduced from the actual input types (see Section 34.2.5). This allows the function to access its actual return type as shown in Section 38.3.2. `$0` is initialized to null and can be modified by the function, so it can be used to hold the return value if desired, though that is not required. `$0` can also be given an alias. For example, this function works on any data type that has a `+` operator:

```
CREATE FUNCTION add_three_values(v1 anyelement, v2 anyelement, v3 anyelement)
RETURNS anyelement AS $$
DECLARE
    result ALIAS FOR $0;
BEGIN
    result := v1 + v2 + v3;
    RETURN result;
END;
$$ LANGUAGE plpgsql;
```

The same effect can be had by declaring one or more output parameters as polymorphic types. In this case the special `$0` parameter is not used; the output parameters themselves serve the same purpose. For example:

```
CREATE FUNCTION add_three_values(v1 anyelement, v2 anyelement, v3 anyelement,
                                OUT sum anyelement)
AS $$
BEGIN
    sum := v1 + v2 + v3;
END;
$$ LANGUAGE plpgsql;
```

### 38.3.2. Copying Types

```
variable%TYPE
```

`%TYPE` provides the data type of a variable or table column. You can use this to declare variables that will hold database values. For example, let's say you have a column named `user_id` in your `users` table. To declare a variable with the same data type as `users.user_id` you write:

```
user_id users.user_id%TYPE;
```

By using `%TYPE` you don't need to know the data type of the structure you are referencing, and most importantly, if the data type of the referenced item changes in the future (for instance: you change the type of `user_id` from `integer` to `real`), you might not need to change your function definition.

`%TYPE` is particularly valuable in polymorphic functions, since the data types needed for internal variables can change from one call to the next. Appropriate variables can be created by applying `%TYPE` to the function's arguments or result placeholders.

### 38.3.3. Row Types

```
name table_name%ROWTYPE;
name composite_type_name;
```

A variable of a composite type is called a *row* variable (or *row-type* variable). Such a variable can hold a whole row of a `SELECT` or `FOR` query result, so long as that query's column set matches the declared type of the variable. The individual fields of the row value are accessed using the usual dot notation, for example `rowvar.field`.

A row variable can be declared to have the same type as the rows of an existing table or view, by using the `table_name%ROWTYPE` notation; or it can be declared by giving a composite type's name. (Since every table has an associated composite type of the same name, it actually does not matter in PostgreSQL whether you write `%ROWTYPE` or not. But the form with `%ROWTYPE` is more portable.)

Parameters to a function can be composite types (complete table rows). In that case, the corresponding identifier `$n` will be a row variable, and fields can be selected from it, for example `$1.user_id`.

Only the user-defined columns of a table row are accessible in a row-type variable, not the OID or other system columns (because the row could be from a view). The fields of the row type inherit the table's field size or precision for data types such as `char(n)`.

Here is an example of using composite types. `table1` and `table2` are existing tables having at least the mentioned fields:

```
CREATE FUNCTION merge_fields(t_row table1) RETURNS text AS $$
DECLARE
    t2_row table2%ROWTYPE;
BEGIN
    SELECT * INTO t2_row FROM table2 WHERE ... ;
    RETURN t_row.f1 || t2_row.f3 || t_row.f5 || t2_row.f7;
END;
$$ LANGUAGE plpgsql;
```

```
SELECT merge_fields(t.*) FROM table1 t WHERE ... ;
```

### 38.3.4. Record Types

```
name RECORD;
```

Record variables are similar to row-type variables, but they have no predefined structure. They take on the actual row structure of the row they are assigned during a `SELECT` or `FOR` command. The substructure of a record variable can change each time it is assigned to. A consequence of this is that until a record variable is first assigned to, it has no substructure, and any attempt to access a field in it will draw a run-time error.

Note that `RECORD` is not a true data type, only a placeholder. One should also realize that when a PL/pgSQL function is declared to return type `record`, this is not quite the same concept as a record variable, even though such a function might use a record variable to hold its result. In both cases the actual row structure is unknown when the function is written, but for a function returning `record` the actual structure is determined when the calling query is parsed, whereas a record variable can change its row structure on-the-fly.

### 38.3.5. RENAME

```
RENAME oldname TO newname;
```

Using the `RENAME` declaration you can change the name of a variable, record or row. This is primarily useful if `NEW` or `OLD` should be referenced by another name inside a trigger procedure. See also `ALIAS`.

Examples:

```
RENAME id TO user_id;
RENAME this_var TO that_var;
```

**Note:** `RENAME` appears to be broken as of PostgreSQL 7.3. Fixing this is of low priority, since `ALIAS` covers most of the practical uses of `RENAME`.

## 38.4. Expressions

All expressions used in PL/pgSQL statements are processed using the server's main SQL executor. For

example, when you write a PL/pgSQL statement like

```
IF expression THEN ...
```

PL/pgSQL will evaluate the expression by feeding a query like

```
SELECT expression
```

to the main SQL engine. While forming the `SELECT` command, any occurrences of PL/pgSQL variable names are replaced by parameters, as discussed in detail in Section 38.10.1. This allows the query plan for the `SELECT` to be prepared just once and then reused for subsequent evaluations with different values of the variables. Thus, what really happens on first use of an expression is essentially a `PREPARE` command. For example, if we have declared two integer variables `x` and `y`, and we write

```
IF x < y THEN ...
```

what happens behind the scenes is

```
PREPARE statement_name(integer, integer) AS SELECT $1 < $2;
```

and then this prepared statement is `EXECUTED` for each execution of the `IF` statement, with the current values of the PL/pgSQL variables supplied as parameter values. The query plan prepared in this way is saved for the life of the database connection, as described in Section 38.10.2. Normally these details are not important to a PL/pgSQL user, but they are useful to know when trying to diagnose a problem.

## 38.5. Basic Statements

In this section and the following ones, we describe all the statement types that are explicitly understood by PL/pgSQL. Anything not recognized as one of these statement types is presumed to be an SQL command and is sent to the main database engine to execute, as described in Section 38.5.2 and Section 38.5.3.

### 38.5.1. Assignment

An assignment of a value to a PL/pgSQL variable or row/record field is written as:

```
variable := expression;
```

As explained above, the expression in such a statement is evaluated by means of an SQL `SELECT` command sent to the main database engine. The expression must yield a single value.

If the expression's result data type doesn't match the variable's data type, or the variable has a specific size/precision (like `char(20)`), the result value will be implicitly converted by the PL/pgSQL interpreter using the result type's output-function and the variable type's input-function. Note that this could potentially result in run-time errors generated by the input function, if the string form of the result value is not acceptable to the input function.

Examples:

```
tax := subtotal * 0.06;
my_record.user_id := 20;
```

### 38.5.2. Executing a Command With No Result

For any SQL command that does not return rows, for example `INSERT` without a `RETURNING` clause, you can execute the command within a PL/pgSQL function just by writing the command.

Any PL/pgSQL variable name appearing in the command text is replaced by a parameter symbol, and then the current value of the variable is provided as the parameter value at run time. This is exactly like the processing described earlier for expressions; for details see Section 38.10.1. As an example, if you write:

```
DECLARE
    key TEXT;
    delta INTEGER;
BEGIN
    ...
    UPDATE mytab SET val = val + delta WHERE id = key;
```

the command text seen by the main SQL engine will look like:

```
UPDATE mytab SET val = val + $1 WHERE id = $2;
```

Although you don't normally have to think about this, it's helpful to know it when you need to make sense of syntax-error messages.

#### Caution

PL/pgSQL will substitute for any identifier matching one of the function's declared variables; it is not bright enough to know whether that's what you meant! Thus, it is a bad idea to use a variable name that is the same as any table, column, or function name that you need to reference in commands within the function. For more discussion see Section 38.10.1.

When executing a SQL command in this way, PL/pgSQL plans the command just once and re-uses the plan on subsequent executions, for the life of the database connection. The implications of this are discussed in detail in Section 38.10.2.

Sometimes it is useful to evaluate an expression or `SELECT` query but discard the result, for example when calling a function that has side-effects but no useful result value. To do this in PL/pgSQL, use the `PERFORM` statement:

```
PERFORM query;
```

This executes *query* and discards the result. Write the *query* the same way you would write an SQL `SELECT` command, but replace the initial keyword `SELECT` with `PERFORM`. PL/pgSQL variables will be substituted into the query just as for commands that return no result, and the plan is cached in the same way. Also, the special variable `FOUND` is set to true if the query produced at least one row, or false if it produced no rows (see Section 38.5.5).

**Note:** One might expect that writing `SELECT` directly would accomplish this result, but at present the only accepted way to do it is `PERFORM`. A SQL command that can return rows, such as `SELECT`, will be rejected as an error unless it has an `INTO` clause as discussed in the next section.

An example:

```
PERFORM create_mv('cs_session_page_requests_mv', my_query);
```

### 38.5.3. Executing a Query with a Single-Row Result

The result of a SQL command yielding a single row (possibly of multiple columns) can be assigned to a record variable, row-type variable, or list of scalar variables. This is done by writing the base SQL command and adding an `INTO` clause. For example,

```
SELECT select_expressions INTO [STRICT] target FROM ...;
INSERT ... RETURNING expressions INTO [STRICT] target;
UPDATE ... RETURNING expressions INTO [STRICT] target;
DELETE ... RETURNING expressions INTO [STRICT] target;
```

where *target* can be a record variable, a row variable, or a comma-separated list of simple variables and record/row fields. PL/pgSQL variables will be substituted into the rest of the query, and the plan is cached, just as described above for commands that do not return rows. This works for `SELECT`, `INSERT/UPDATE/DELETE` with `RETURNING`, and utility commands that return row-set results (such as `EXPLAIN`). Except for the `INTO` clause, the SQL command is the same as it would be written outside PL/pgSQL.

**Tip:** Note that this interpretation of `SELECT` with `INTO` is quite different from PostgreSQL's regular `SELECT INTO` command, wherein the `INTO` target is a newly created table. If you want to create a table from a `SELECT` result inside a PL/pgSQL function, use the syntax `CREATE TABLE ... AS SELECT`.

If a row or a variable list is used as target, the query's result columns must exactly match the structure of the target as to number and data types, or a run-time error occurs. When a record variable is the target, it automatically configures itself to the row type of the query result columns.

The `INTO` clause can appear almost anywhere in the SQL command. Customarily it is written either just before or just after the list of *select\_expressions* in a `SELECT` command, or at the end of the command for other command types. It is recommended that you follow this convention in case the PL/pgSQL parser becomes stricter in future versions.

If `STRICT` is not specified in the `INTO` clause, then *target* will be set to the first row returned by the query, or to nulls if the query returned no rows. (Note that “the first row” is not well-defined unless you've used `ORDER BY`.) Any result rows after the first row are discarded. You can check the special `FOUND` variable (see Section 38.5.5) to determine whether a row was returned:

```
SELECT * INTO myrec FROM emp WHERE empname = myname;
IF NOT FOUND THEN
```

```
    RAISE EXCEPTION 'employee % not found', myname;
END IF;
```

If the `STRICT` option is specified, the query must return exactly one row or a run-time error will be reported, either `NO_DATA_FOUND` (no rows) or `TOO_MANY_ROWS` (more than one row). You can use an exception block if you wish to catch the error, for example:

```
BEGIN
    SELECT * INTO STRICT myrec FROM emp WHERE empname = myname;
EXCEPTION
    WHEN NO_DATA_FOUND THEN
        RAISE EXCEPTION 'employee % not found', myname;
    WHEN TOO_MANY_ROWS THEN
        RAISE EXCEPTION 'employee % not unique', myname;
END;
```

Successful execution of a command with `STRICT` always sets `FOUND` to true.

For `INSERT/UPDATE/DELETE` with `RETURNING`, PL/pgSQL reports an error for more than one returned row, even when `STRICT` is not specified. This is because there is no option such as `ORDER BY` with which to determine which affected row should be returned.

**Note:** The `STRICT` option matches the behavior of Oracle PL/SQL's `SELECT INTO` and related statements.

To handle cases where you need to process multiple result rows from a SQL query, see Section 38.6.4.

### 38.5.4. Executing Dynamic Commands

Oftentimes you will want to generate dynamic commands inside your PL/pgSQL functions, that is, commands that will involve different tables or different data types each time they are executed. PL/pgSQL's normal attempts to cache plans for commands (as discussed in Section 38.10.2) will not work in such scenarios. To handle this sort of problem, the `EXECUTE` statement is provided:

```
EXECUTE command-string [ INTO [STRICT] target ];
```

where *command-string* is an expression yielding a string (of type `text`) containing the command to be executed and *target* is a record variable, row variable, or a comma-separated list of simple variables and record/row fields.

No substitution of PL/pgSQL variables is done on the computed command string. Any required variable values must be inserted in the command string as it is constructed.

Also, there is no plan caching for commands executed via `EXECUTE`. Instead, the command is prepared each time the statement is run. Thus the command string can be dynamically created within the function to perform actions on different tables and columns.

The `INTO` clause specifies where the results of a SQL command returning rows should be assigned. If a row or variable list is provided, it must exactly match the structure of the query's results (when a record variable is used, it will configure itself to match the result structure automatically). If multiple rows are

returned, only the first will be assigned to the `INTO` variable. If no rows are returned, `NULL` is assigned to the `INTO` variable(s). If no `INTO` clause is specified, the query results are discarded.

If the `STRICT` option is given, an error is reported unless the query produces exactly one row.

`SELECT INTO` is not currently supported within `EXECUTE`; instead, execute a plain `SELECT` command and specify `INTO` as part of the `EXECUTE` itself.

**Note:** The PL/pgSQL `EXECUTE` statement is not related to the `EXECUTE` SQL statement supported by the PostgreSQL server. The server's `EXECUTE` statement cannot be used directly within PL/pgSQL functions (and is not needed).

When working with dynamic commands you will often have to handle escaping of single quotes. The recommended method for quoting fixed text in your function body is dollar quoting. (If you have legacy code that does not use dollar quoting, please refer to the overview in Section 38.11.1, which can save you some effort when translating said code to a more reasonable scheme.)

Dynamic values that are to be inserted into the constructed query require careful handling since they might themselves contain quote characters. An example (this assumes that you are using dollar quoting for the function as a whole, so the quote marks need not be doubled):

```
EXECUTE 'UPDATE tbl SET '
      || quote_ident(colname)
      || ' = '
      || quote_literal(newvalue)
      || ' WHERE key = '
      || quote_literal(keyvalue);
```

This example demonstrates the use of the `quote_ident` and `quote_literal` functions. For safety, expressions containing column and table identifiers should be passed to `quote_ident`. Expressions containing values that should be literal strings in the constructed command should be passed to `quote_literal`. Both take the appropriate steps to return the input text enclosed in double or single quotes respectively, with any embedded special characters properly escaped.

Note that dollar quoting is only useful for quoting fixed text. It would be a very bad idea to try to do the above example as:

```
EXECUTE 'UPDATE tbl SET '
      || quote_ident(colname)
      || ' = $$'
      || newvalue
      || '$$ WHERE key = '
      || quote_literal(keyvalue);
```

because it would break if the contents of `newvalue` happened to contain `$$`. The same objection would apply to any other dollar-quoting delimiter you might pick. So, to safely quote text that is not known in advance, you *must* use `quote_literal`.

A much larger example of a dynamic command and `EXECUTE` can be seen in Example 38-6, which builds and executes a `CREATE FUNCTION` command to define a new function.

### 38.5.5. Obtaining the Result Status

There are several ways to determine the effect of a command. The first method is to use the `GET DIAGNOSTICS` command, which has the form:

```
GET DIAGNOSTICS variable = item [ , ... ];
```

This command allows retrieval of system status indicators. Each *item* is a key word identifying a state value to be assigned to the specified variable (which should be of the right data type to receive it). The currently available status items are `ROW_COUNT`, the number of rows processed by the last SQL command sent down to the SQL engine, and `RESULT_OID`, the OID of the last row inserted by the most recent SQL command. Note that `RESULT_OID` is only useful after an `INSERT` command into a table containing OIDs.

An example:

```
GET DIAGNOSTICS integer_var = ROW_COUNT;
```

The second method to determine the effects of a command is to check the special variable named `FOUND`, which is of type `boolean`. `FOUND` starts out false within each PL/pgSQL function call. It is set by each of the following types of statements:

- A `SELECT INTO` statement sets `FOUND` true if a row is assigned, false if no row is returned.
- A `PERFORM` statement sets `FOUND` true if it produces (and discards) one or more rows, false if no row is produced.
- `UPDATE`, `INSERT`, and `DELETE` statements set `FOUND` true if at least one row is affected, false if no row is affected.
- A `FETCH` statement sets `FOUND` true if it returns a row, false if no row is returned.
- A `MOVE` statement sets `FOUND` true if it successfully repositions the cursor, false otherwise.
- A `FOR` statement sets `FOUND` true if it iterates one or more times, else false. This applies to all three variants of the `FOR` statement (integer `FOR` loops, record-set `FOR` loops, and dynamic record-set `FOR` loops). `FOUND` is set this way when the `FOR` loop exits; inside the execution of the loop, `FOUND` is not modified by the `FOR` statement, although it might be changed by the execution of other statements within the loop body.

`FOUND` is a local variable within each PL/pgSQL function; any changes to it affect only the current function.

### 38.5.6. Doing Nothing At All

Sometimes a placeholder statement that does nothing is useful. For example, it can indicate that one arm of an if/then/else chain is deliberately empty. For this purpose, use the `NULL` statement:

```
NULL;
```

For example, the following two fragments of code are equivalent:

```

BEGIN
    y := x / 0;
EXCEPTION
    WHEN division_by_zero THEN
        NULL; -- ignore the error
END;

BEGIN
    y := x / 0;
EXCEPTION
    WHEN division_by_zero THEN -- ignore the error
END;

```

Which is preferable is a matter of taste.

**Note:** In Oracle's PL/SQL, empty statement lists are not allowed, and so `NULL` statements are *required* for situations such as this. PL/pgSQL allows you to just write nothing, instead.

## 38.6. Control Structures

Control structures are probably the most useful (and important) part of PL/pgSQL. With PL/pgSQL's control structures, you can manipulate PostgreSQL data in a very flexible and powerful way.

### 38.6.1. Returning From a Function

There are two commands available that allow you to return data from a function: `RETURN` and `RETURN NEXT`.

#### 38.6.1.1. RETURN

```
RETURN expression;
```

`RETURN` with an expression terminates the function and returns the value of *expression* to the caller. This form is to be used for PL/pgSQL functions that do not return a set.

When returning a scalar type, any expression can be used. The expression's result will be automatically cast into the function's return type as described for assignments. To return a composite (row) value, you must write a record or row variable as the *expression*.

If you declared the function with output parameters, write just `RETURN` with no expression. The current values of the output parameter variables will be returned.

If you declared the function to return `void`, a `RETURN` statement can be used to exit the function early; but do not write an expression following `RETURN`.

The return value of a function cannot be left undefined. If control reaches the end of the top-level block of the function without hitting a `RETURN` statement, a run-time error will occur. This restriction does not

apply to functions with output parameters and functions returning `void`, however. In those cases a `RETURN` statement is automatically executed if the top-level block finishes.

### 38.6.1.2. RETURN NEXT and RETURN QUERY

```
RETURN NEXT expression;
RETURN QUERY query;
```

When a PL/pgSQL function is declared to return `SETOF sometype`, the procedure to follow is slightly different. In that case, the individual items to return are specified by a sequence of `RETURN NEXT` or `RETURN QUERY` commands, and then a final `RETURN` command with no argument is used to indicate that the function has finished executing. `RETURN NEXT` can be used with both scalar and composite data types; with a composite result type, an entire “table” of results will be returned. `RETURN QUERY` appends the results of executing a query to the function’s result set. `RETURN NEXT` and `RETURN QUERY` can be freely intermixed in a single set-returning function, in which case their results will be concatenated.

`RETURN NEXT` and `RETURN QUERY` do not actually return from the function — they simply append zero or more rows to the function’s result set. Execution then continues with the next statement in the PL/pgSQL function. As successive `RETURN NEXT` or `RETURN QUERY` commands are executed, the result set is built up. A final `RETURN`, which should have no argument, causes control to exit the function (or you can just let control reach the end of the function).

If you declared the function with output parameters, write just `RETURN NEXT` with no expression. On each execution, the current values of the output parameter variable(s) will be saved for eventual return as a row of the result. Note that you must declare the function as returning `SETOF record` when there are multiple output parameters, or `SETOF sometype` when there is just one output parameter of type *sometype*, in order to create a set-returning function with output parameters.

Here is an example of a function using `RETURN NEXT`:

```
CREATE TABLE foo (fooid INT, foosubid INT, fooname TEXT);
INSERT INTO foo VALUES (1, 2, 'three');
INSERT INTO foo VALUES (4, 5, 'six');

CREATE OR REPLACE FUNCTION getAllFoo() RETURNS SETOF foo AS
$BODY$
DECLARE
    r foo%rowtype;
BEGIN
    FOR r IN SELECT * FROM foo
        WHERE fooid > 0
    LOOP
        -- can do some processing here
        RETURN NEXT r; -- return current row of SELECT
    END LOOP;
    RETURN;
END
$BODY$
LANGUAGE 'plpgsql' ;

SELECT * FROM getallfoo();
```

Note that functions using `RETURN NEXT` or `RETURN QUERY` must be called as a table source in a `FROM` clause.

**Note:** The current implementation of `RETURN NEXT` and `RETURN QUERY` stores the entire result set before returning from the function, as discussed above. That means that if a PL/pgSQL function produces a very large result set, performance might be poor: data will be written to disk to avoid memory exhaustion, but the function itself will not return until the entire result set has been generated. A future version of PL/pgSQL might allow users to define set-returning functions that do not have this limitation. Currently, the point at which data begins being written to disk is controlled by the `work_mem` configuration variable. Administrators who have sufficient memory to store larger result sets in memory should consider increasing this parameter.

## 38.6.2. Conditionals

`IF` statements let you execute commands based on certain conditions. PL/pgSQL has five forms of `IF`:

- `IF ... THEN`
- `IF ... THEN ... ELSE`
- `IF ... THEN ... ELSE IF`
- `IF ... THEN ... ELSIF ... THEN ... ELSE`
- `IF ... THEN ... ELSEIF ... THEN ... ELSE`

### 38.6.2.1. IF-THEN

```
IF boolean-expression THEN
    statements
END IF;
```

`IF-THEN` statements are the simplest form of `IF`. The statements between `THEN` and `END IF` will be executed if the condition is true. Otherwise, they are skipped.

Example:

```
IF v_user_id <> 0 THEN
    UPDATE users SET email = v_email WHERE user_id = v_user_id;
END IF;
```

**38.6.2.2. IF-THEN-ELSE**

```

IF boolean-expression THEN
    statements
ELSE
    statements
END IF;

```

IF-THEN-ELSE statements add to IF-THEN by letting you specify an alternative set of statements that should be executed if the condition evaluates to false.

Examples:

```

IF parentid IS NULL OR parentid = ''
THEN
    RETURN fullname;
ELSE
    RETURN hp_true_filename(parentid) || '/' || fullname;
END IF;

IF v_count > 0 THEN
    INSERT INTO users_count (count) VALUES (v_count);
    RETURN 't';
ELSE
    RETURN 'f';
END IF;

```

**38.6.2.3. IF-THEN-ELSE IF**

IF statements can be nested, as in the following example:

```

IF demo_row.sex = 'm' THEN
    pretty_sex := 'man';
ELSE
    IF demo_row.sex = 'f' THEN
        pretty_sex := 'woman';
    END IF;
END IF;

```

When you use this form, you are actually nesting an IF statement inside the ELSE part of an outer IF statement. Thus you need one END IF statement for each nested IF and one for the parent IF-ELSE. This is workable but grows tedious when there are many alternatives to be checked. Hence the next form.

**38.6.2.4. IF-THEN-ELSIF-ELSE**

```

IF boolean-expression THEN
    statements
[ ELSEIF boolean-expression THEN
    statements

```

```

    statements
[ ELSIF boolean-expression THEN
    statements
...]]
[ ELSE
    statements ]
END IF;

```

IF-THEN-ELSIF-ELSE provides a more convenient method of checking many alternatives in one statement. Functionally it is equivalent to nested IF-THEN-ELSE-IF-THEN commands, but only one `END IF` is needed.

Here is an example:

```

IF number = 0 THEN
    result := 'zero';
ELSIF number > 0 THEN
    result := 'positive';
ELSIF number < 0 THEN
    result := 'negative';
ELSE
    -- hmm, the only other possibility is that number is null
    result := 'NULL';
END IF;

```

#### 38.6.2.5. IF-THEN-ELSEIF-ELSE

ELSEIF is an alias for ELSIF.

### 38.6.3. Simple Loops

With the `LOOP`, `EXIT`, `CONTINUE`, `WHILE`, and `FOR` statements, you can arrange for your PL/pgSQL function to repeat a series of commands.

#### 38.6.3.1. LOOP

```

[ <<label>> ]
LOOP
    statements
END LOOP [ label ];

```

`LOOP` defines an unconditional loop that is repeated indefinitely until terminated by an `EXIT` or `RETURN` statement. The optional *label* can be used by `EXIT` and `CONTINUE` statements in nested loops to specify which loop the statement should be applied to.

**38.6.3.2. EXIT**

```
EXIT [ label ] [ WHEN boolean-expression ];
```

If no *label* is given, the innermost loop is terminated and the statement following `END LOOP` is executed next. If *label* is given, it must be the label of the current or some outer level of nested loop or block. Then the named loop or block is terminated and control continues with the statement after the loop's/block's corresponding `END`.

If `WHEN` is specified, the loop exit occurs only if *boolean-expression* is true. Otherwise, control passes to the statement after `EXIT`.

`EXIT` can be used with all types of loops; it is not limited to use with unconditional loops. When used with a `BEGIN` block, `EXIT` passes control to the next statement after the end of the block.

Examples:

```
LOOP
    -- some computations
    IF count > 0 THEN
        EXIT; -- exit loop
    END IF;
END LOOP;

LOOP
    -- some computations
    EXIT WHEN count > 0; -- same result as previous example
END LOOP;

BEGIN
    -- some computations
    IF stocks > 100000 THEN
        EXIT; -- causes exit from the BEGIN block
    END IF;
END;
```

**38.6.3.3. CONTINUE**

```
CONTINUE [ label ] [ WHEN boolean-expression ];
```

If no *label* is given, the next iteration of the innermost loop is begun. That is, all statements remaining in the loop body are skipped, and control returns to the loop control expression (if any) to determine whether another loop iteration is needed. If *label* is present, it specifies the label of the loop whose execution will be continued.

If `WHEN` is specified, the next iteration of the loop is begun only if *boolean-expression* is true. Otherwise, control passes to the statement after `CONTINUE`.

`CONTINUE` can be used with all types of loops; it is not limited to use with unconditional loops.

Examples:

```

LOOP
    -- some computations
    EXIT WHEN count > 100;
    CONTINUE WHEN count < 50;
    -- some computations for count IN [50 .. 100]
END LOOP;

```

### 38.6.3.4. WHILE

```

[ <<label>> ]
WHILE boolean-expression LOOP
    statements
END LOOP [ label ];

```

The `WHILE` statement repeats a sequence of statements so long as the *boolean-expression* evaluates to true. The expression is checked just before each entry to the loop body.

For example:

```

WHILE amount_owed > 0 AND gift_certificate_balance > 0 LOOP
    -- some computations here
END LOOP;

WHILE NOT done LOOP
    -- some computations here
END LOOP;

```

### 38.6.3.5. FOR (integer variant)

```

[ <<label>> ]
FOR name IN [ REVERSE ] expression .. expression [ BY expression ] LOOP
    statements
END LOOP [ label ];

```

This form of `FOR` creates a loop that iterates over a range of integer values. The variable *name* is automatically defined as type `integer` and exists only inside the loop (any existing definition of the variable *name* is ignored within the loop). The two expressions giving the lower and upper bound of the range are evaluated once when entering the loop. If the `BY` clause isn't specified the iteration step is 1, otherwise it's the value specified in the `BY` clause, which again is evaluated once on loop entry. If `REVERSE` is specified then the step value is subtracted, rather than added, after each iteration.

Some examples of integer `FOR` loops:

```

FOR i IN 1..10 LOOP
    -- i will take on the values 1,2,3,4,5,6,7,8,9,10 within the loop
END LOOP;

```

```

FOR i IN REVERSE 10..1 LOOP
    -- i will take on the values 10,9,8,7,6,5,4,3,2,1 within the loop
END LOOP;

FOR i IN REVERSE 10..1 BY 2 LOOP
    -- i will take on the values 10,8,6,4,2 within the loop
END LOOP;

```

If the lower bound is greater than the upper bound (or less than, in the `REVERSE` case), the loop body is not executed at all. No error is raised.

If a *label* is attached to the `FOR` loop then the integer loop variable can be referenced with a qualified name, using that *label*.

### 38.6.4. Looping Through Query Results

Using a different type of `FOR` loop, you can iterate through the results of a query and manipulate that data accordingly. The syntax is:

```

[ <<label>> ]
FOR target IN query LOOP
    statements
END LOOP [ label ];

```

The *target* is a record variable, row variable, or comma-separated list of scalar variables. The *target* is successively assigned each row resulting from the *query* and the loop body is executed for each row. Here is an example:

```

CREATE FUNCTION cs_refresh_mviews() RETURNS integer AS $$
DECLARE
    mviews RECORD;
BEGIN
    PERFORM cs_log('Refreshing materialized views...');

    FOR mviews IN SELECT * FROM cs_materialized_views ORDER BY sort_key LOOP

        -- Now "mviews" has one record from cs_materialized_views

        PERFORM cs_log('Refreshing materialized view ' || quote_ident(mviews.mv_name) || ' ');
        EXECUTE 'TRUNCATE TABLE ' || quote_ident(mviews.mv_name);
        EXECUTE 'INSERT INTO ' || quote_ident(mviews.mv_name) || ' ' || mviews.mv_query;
    END LOOP;

    PERFORM cs_log('Done refreshing materialized views. ');
    RETURN 1;
END;
$$ LANGUAGE plpgsql;

```

If the loop is terminated by an `EXIT` statement, the last assigned row value is still accessible after the loop.

The *query* used in this type of `FOR` statement can be any SQL command that returns rows to the caller: `SELECT` is the most common case, but you can also use `INSERT`, `UPDATE`, or `DELETE` with a `RETURNING` clause. Some utility commands such as `EXPLAIN` will work too.

PL/pgSQL variables are substituted into the query text, and the query plan is cached for possible re-use, as discussed in detail in Section 38.10.1 and Section 38.10.2.

The `FOR-IN-EXECUTE` statement is another way to iterate over rows:

```
[ <<label>> ]
FOR target IN EXECUTE text_expression LOOP
    statements
END LOOP [ label ];
```

This is like the previous form, except that the source query is specified as a string expression, which is evaluated and replanned on each entry to the `FOR` loop. This allows the programmer to choose the speed of a preplanned query or the flexibility of a dynamic query, just as with a plain `EXECUTE` statement.

### 38.6.5. Trapping Errors

By default, any error occurring in a PL/pgSQL function aborts execution of the function, and indeed of the surrounding transaction as well. You can trap errors and recover from them by using a `BEGIN` block with an `EXCEPTION` clause. The syntax is an extension of the normal syntax for a `BEGIN` block:

```
[ <<label>> ]
[ DECLARE
    declarations ]
BEGIN
    statements
EXCEPTION
    WHEN condition [ OR condition ... ] THEN
        handler_statements
    [ WHEN condition [ OR condition ... ] THEN
        handler_statements
    ... ]
END;
```

If no error occurs, this form of block simply executes all the *statements*, and then control passes to the next statement after `END`. But if an error occurs within the *statements*, further processing of the *statements* is abandoned, and control passes to the `EXCEPTION` list. The list is searched for the first *condition* matching the error that occurred. If a match is found, the corresponding *handler\_statements* are executed, and then control passes to the next statement after `END`. If no match is found, the error propagates out as though the `EXCEPTION` clause were not there at all: the error can be caught by an enclosing block with `EXCEPTION`, or if there is none it aborts processing of the function.

The *condition* names can be any of those shown in Appendix A. A category name matches any error within its category. The special condition name `OTHERS` matches every error type except `QUERY_CANCELED`. (It is possible, but often unwise, to trap `QUERY_CANCELED` by name.) Condition names are not case-sensitive.

If a new error occurs within the selected *handler\_statements*, it cannot be caught by this `EXCEPTION` clause, but is propagated out. A surrounding `EXCEPTION` clause could catch it.

When an error is caught by an `EXCEPTION` clause, the local variables of the PL/pgSQL function remain as they were when the error occurred, but all changes to persistent database state within the block are rolled back. As an example, consider this fragment:

```
INSERT INTO mytab(firstname, lastname) VALUES('Tom', 'Jones');
BEGIN
    UPDATE mytab SET firstname = 'Joe' WHERE lastname = 'Jones';
    x := x + 1;
    y := x / 0;
EXCEPTION
    WHEN division_by_zero THEN
        RAISE NOTICE 'caught division_by_zero';
        RETURN x;
END;
```

When control reaches the assignment to `y`, it will fail with a `division_by_zero` error. This will be caught by the `EXCEPTION` clause. The value returned in the `RETURN` statement will be the incremented value of `x`, but the effects of the `UPDATE` command will have been rolled back. The `INSERT` command preceding the block is not rolled back, however, so the end result is that the database contains Tom Jones not Joe Jones.

**Tip:** A block containing an `EXCEPTION` clause is significantly more expensive to enter and exit than a block without one. Therefore, don't use `EXCEPTION` without need.

Within an exception handler, the `SQLSTATE` variable contains the error code that corresponds to the exception that was raised (refer to Table A-1 for a list of possible error codes). The `SQLERRM` variable contains the error message associated with the exception. These variables are undefined outside exception handlers.

### Example 38-1. Exceptions with `UPDATE/INSERT`

This example uses exception handling to perform either `UPDATE` or `INSERT`, as appropriate:

```
CREATE TABLE db (a INT PRIMARY KEY, b TEXT);

CREATE FUNCTION merge_db(key INT, data TEXT) RETURNS VOID AS
$$
BEGIN
    LOOP
        -- first try to update the key
        UPDATE db SET b = data WHERE a = key;
        IF found THEN
            RETURN;
        END IF;
        -- not there, so try to insert the key
        -- if someone else inserts the same key concurrently,
        -- we could get a unique-key failure
        BEGIN
            INSERT INTO db(a,b) VALUES (key, data);
```

```

        RETURN;
    EXCEPTION WHEN unique_violation THEN
        -- do nothing, and loop to try the UPDATE again
    END;
END LOOP;
END;
$$
LANGUAGE plpgsql;

SELECT merge_db(1, 'david');
SELECT merge_db(1, 'dennis');
```

## 38.7. Cursors

Rather than executing a whole query at once, it is possible to set up a *cursor* that encapsulates the query, and then read the query result a few rows at a time. One reason for doing this is to avoid memory overrun when the result contains a large number of rows. (However, PL/pgSQL users do not normally need to worry about that, since FOR loops automatically use a cursor internally to avoid memory problems.) A more interesting usage is to return a reference to a cursor that a function has created, allowing the caller to read the rows. This provides an efficient way to return large row sets from functions.

### 38.7.1. Declaring Cursor Variables

All access to cursors in PL/pgSQL goes through cursor variables, which are always of the special data type `refcursor`. One way to create a cursor variable is just to declare it as a variable of type `refcursor`. Another way is to use the cursor declaration syntax, which in general is:

```
name [ [ NO ] SCROLL ] CURSOR [ ( arguments ) ] FOR query;
```

(FOR can be replaced by IS for Oracle compatibility.) If SCROLL is specified, the cursor will be capable of scrolling backward; if NO SCROLL is specified, backward fetches will be rejected; if neither specification appears, it is query-dependent whether backward fetches will be allowed. *arguments*, if specified, is a comma-separated list of pairs *name datatype* that define names to be replaced by parameter values in the given query. The actual values to substitute for these names will be specified later, when the cursor is opened.

Some examples:

```
DECLARE
    curs1 refcursor;
    curs2 CURSOR FOR SELECT * FROM tenk1;
    curs3 CURSOR (key integer) IS SELECT * FROM tenk1 WHERE unique1 = key;
```

All three of these variables have the data type `refcursor`, but the first can be used with any query, while the second has a fully specified query already *bound* to it, and the last has a parameterized query bound

to it. (key will be replaced by an integer parameter value when the cursor is opened.) The variable `curs1` is said to be *unbound* since it is not bound to any particular query.

## 38.7.2. Opening Cursors

Before a cursor can be used to retrieve rows, it must be *opened*. (This is the equivalent action to the SQL command `DECLARE CURSOR`.) PL/pgSQL has three forms of the `OPEN` statement, two of which use unbound cursor variables while the third uses a bound cursor variable.

### 38.7.2.1. OPEN FOR query

```
OPEN unbound_cursor [ [ NO ] SCROLL ] FOR query;
```

The cursor variable is opened and given the specified query to execute. The cursor cannot be open already, and it must have been declared as an unbound cursor (that is, as a simple `refcursor` variable). The query must be a `SELECT`, or something else that returns rows (such as `EXPLAIN`). The query is treated in the same way as other SQL commands in PL/pgSQL: PL/pgSQL variable names are substituted, and the query plan is cached for possible reuse. When a PL/pgSQL variable is substituted into the cursor query, the value that is substituted is the one it has at the time of the `OPEN`; subsequent changes to the variable will not affect the cursor's behavior. The `SCROLL` and `NO SCROLL` options have the same meanings as for a bound cursor.

An example:

```
OPEN curs1 FOR SELECT * FROM foo WHERE key = mykey;
```

### 38.7.2.2. OPEN FOR EXECUTE

```
OPEN unbound_cursor [ [ NO ] SCROLL ] FOR EXECUTE query_string;
```

The cursor variable is opened and given the specified query to execute. The cursor cannot be open already, and it must have been declared as an unbound cursor (that is, as a simple `refcursor` variable). The query is specified as a string expression, in the same way as in the `EXECUTE` command. As usual, this gives flexibility so the query plan can vary from one run to the next (see Section 38.10.2), and it also means that variable substitution is not done on the command string. The `SCROLL` and `NO SCROLL` options have the same meanings as for a bound cursor.

An example:

```
OPEN curs1 FOR EXECUTE 'SELECT * FROM ' || quote_ident($1);
```

### 38.7.2.3. Opening a Bound Cursor

```
OPEN bound_cursor [ ( argument_values ) ];
```

This form of `OPEN` is used to open a cursor variable whose query was bound to it when it was declared. The cursor cannot be open already. A list of actual argument value expressions must appear if and only if the cursor was declared to take arguments. These values will be substituted in the query. The query plan for a bound cursor is always considered cacheable; there is no equivalent of `EXECUTE` in this case. Notice that `SCROLL` and `NO SCROLL` cannot be specified, as the cursor's scrolling behavior was already determined.

Note that because variable substitution is done on the bound cursor's query, there are two ways to pass values into the cursor: either with an explicit argument to `OPEN`, or implicitly by referencing a PL/pgSQL variable in the query. However, only variables declared before the bound cursor was declared will be substituted into it. In either case the value to be passed is determined at the time of the `OPEN`.

Examples:

```
OPEN curs2;
OPEN curs3(42);
```

### 38.7.3. Using Cursors

Once a cursor has been opened, it can be manipulated with the statements described here.

These manipulations need not occur in the same function that opened the cursor to begin with. You can return a `refcursor` value out of a function and let the caller operate on the cursor. (Internally, a `refcursor` value is simply the string name of a so-called portal containing the active query for the cursor. This name can be passed around, assigned to other `refcursor` variables, and so on, without disturbing the portal.)

All portals are implicitly closed at transaction end. Therefore a `refcursor` value is usable to reference an open cursor only until the end of the transaction.

#### 38.7.3.1. FETCH

```
FETCH [ direction { FROM | IN } ] cursor INTO target;
```

`FETCH` retrieves the next row from the cursor into a target, which might be a row variable, a record variable, or a comma-separated list of simple variables, just like `SELECT INTO`. If there is no next row, the target is set to `NULL(s)`. As with `SELECT INTO`, the special variable `FOUND` can be checked to see whether a row was obtained or not.

The *direction* clause can be any of the variants allowed in the SQL *FETCH* command except the ones that can fetch more than one row; namely, it can be `NEXT`, `PRIOR`, `FIRST`, `LAST`, `ABSOLUTE count`, `RELATIVE count`, `FORWARD`, or `BACKWARD`. Omitting *direction* is the same as specifying `NEXT`. *direction* values that require moving backward are likely to fail unless the cursor was declared or opened with the `SCROLL` option.

*cursor* must be the name of a `refcursor` variable that references an open cursor portal.

Examples:

```
FETCH curs1 INTO rowvar;
```

```

FETCH curs2 INTO foo, bar, baz;
FETCH LAST FROM curs3 INTO x, y;
FETCH RELATIVE -2 FROM curs4 INTO x;

```

### 38.7.3.2. MOVE

```

MOVE [ direction { FROM | IN } ] cursor;

```

`MOVE` repositions a cursor without retrieving any data. `MOVE` works exactly like the `FETCH` command, except it only repositions the cursor and does not return the row moved to. As with `SELECT INTO`, the special variable `FOUND` can be checked to see whether there was a next row to move to.

The options for the *direction* clause are the same as for `FETCH`, namely `NEXT`, `PRIOR`, `FIRST`, `LAST`, `ABSOLUTE count`, `RELATIVE count`, `FORWARD`, or `BACKWARD`. Omitting *direction* is the same as specifying `NEXT`. *direction* values that require moving backward are likely to fail unless the cursor was declared or opened with the `SCROLL` option.

Examples:

```

MOVE curs1;
MOVE LAST FROM curs3;
MOVE RELATIVE -2 FROM curs4;

```

### 38.7.3.3. UPDATE/DELETE WHERE CURRENT OF

```

UPDATE table SET ... WHERE CURRENT OF cursor;
DELETE FROM table WHERE CURRENT OF cursor;

```

When a cursor is positioned on a table row, that row can be updated or deleted using the cursor to identify the row. Note that this only works for simple (non-join, non-grouping) cursor queries. For additional information see the *DECLARE* reference page.

An example:

```

UPDATE foo SET dataval = myval WHERE CURRENT OF curs1;

```

### 38.7.3.4. CLOSE

```

CLOSE cursor;

```

`CLOSE` closes the portal underlying an open cursor. This can be used to release resources earlier than end of transaction, or to free up the cursor variable to be opened again.

An example:

```
CLOSE curs1;
```

### 38.7.3.5. Returning Cursors

PL/pgSQL functions can return cursors to the caller. This is useful to return multiple rows or columns, especially with very large result sets. To do this, the function opens the cursor and returns the cursor name to the caller (or simply opens the cursor using a portal name specified by or otherwise known to the caller). The caller can then fetch rows from the cursor. The cursor can be closed by the caller, or it will be closed automatically when the transaction closes.

The portal name used for a cursor can be specified by the programmer or automatically generated. To specify a portal name, simply assign a string to the `refcursor` variable before opening it. The string value of the `refcursor` variable will be used by `OPEN` as the name of the underlying portal. However, if the `refcursor` variable is null, `OPEN` automatically generates a name that does not conflict with any existing portal, and assigns it to the `refcursor` variable.

**Note:** A bound cursor variable is initialized to the string value representing its name, so that the portal name is the same as the cursor variable name, unless the programmer overrides it by assignment before opening the cursor. But an unbound cursor variable defaults to the null value initially, so it will receive an automatically-generated unique name, unless overridden.

The following example shows one way a cursor name can be supplied by the caller:

```
CREATE TABLE test (col text);
INSERT INTO test VALUES ('123');

CREATE FUNCTION reffunc(refcursor) RETURNS refcursor AS '
BEGIN
    OPEN $1 FOR SELECT col FROM test;
    RETURN $1;
END;
' LANGUAGE plpgsql;

BEGIN;
SELECT reffunc('funcursor');
FETCH ALL IN funcursor;
COMMIT;
```

The following example uses automatic cursor name generation:

```
CREATE FUNCTION reffunc2() RETURNS refcursor AS '
DECLARE
    ref refcursor;
BEGIN
    OPEN ref FOR SELECT col FROM test;
    RETURN ref;
```

```

END;
' LANGUAGE plpgsql;

BEGIN;
SELECT reffunc2();

      reffunc2
-----
<unnamed cursor 1>
(1 row)

FETCH ALL IN "<unnamed cursor 1>";
COMMIT;

```

The following example shows one way to return multiple cursors from a single function:

```

CREATE FUNCTION myfunc(refcursor, refcursor) RETURNS SETOF refcursor AS $$
BEGIN
    OPEN $1 FOR SELECT * FROM table_1;
    RETURN NEXT $1;
    OPEN $2 FOR SELECT * FROM table_2;
    RETURN NEXT $2;
END;
$$ LANGUAGE plpgsql;

-- need to be in a transaction to use cursors.
BEGIN;

SELECT * FROM myfunc('a', 'b');

FETCH ALL FROM a;
FETCH ALL FROM b;
COMMIT;

```

## 38.8. Errors and Messages

Use the `RAISE` statement to report messages and raise errors.

```
RAISE level 'format' [, expression [, ...]];
```

Possible levels are `DEBUG`, `LOG`, `INFO`, `NOTICE`, `WARNING`, and `EXCEPTION`. `EXCEPTION` raises an error (which normally aborts the current transaction); the other levels only generate messages of different priority levels. Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the `log_min_messages` and `client_min_messages` configuration variables. See Chapter 18 for more information.

Inside the format string, % is replaced by the next optional argument's string representation. Write %% to emit a literal %. Arguments can be simple variables or expressions, but the format must be a simple string literal.

In this example, the value of `v_job_id` will replace the % in the string:

```
RAISE NOTICE 'Calling cs_create_job(%)', v_job_id;
```

This example will abort the transaction with the given error message:

```
RAISE EXCEPTION 'Nonexistent ID --> %', user_id;
```

`RAISE EXCEPTION` presently always generates the same `SQLSTATE` code, `P0001`, no matter what message it is invoked with. It is possible to trap this exception with `EXCEPTION ... WHEN RAISE_EXCEPTION THEN ...` but there is no way to tell one `RAISE` from another.

## 38.9. Trigger Procedures

PL/pgSQL can be used to define trigger procedures. A trigger procedure is created with the `CREATE FUNCTION` command, declaring it as a function with no arguments and a return type of `trigger`. Note that the function must be declared with no arguments even if it expects to receive arguments specified in `CREATE TRIGGER` — trigger arguments are passed via `TG_ARGV`, as described below.

When a PL/pgSQL function is called as a trigger, several special variables are created automatically in the top-level block. They are:

`NEW`

Data type `RECORD`; variable holding the new database row for `INSERT/UPDATE` operations in row-level triggers. This variable is `NULL` in statement-level triggers.

`OLD`

Data type `RECORD`; variable holding the old database row for `UPDATE/DELETE` operations in row-level triggers. This variable is `NULL` in statement-level triggers.

`TG_NAME`

Data type `name`; variable that contains the name of the trigger actually fired.

`TG_WHEN`

Data type `text`; a string of either `BEFORE` or `AFTER` depending on the trigger's definition.

`TG_LEVEL`

Data type `text`; a string of either `ROW` or `STATEMENT` depending on the trigger's definition.

`TG_OP`

Data type `text`; a string of `INSERT`, `UPDATE`, or `DELETE` telling for which operation the trigger was fired.

TG\_RELID

Data type `oid`; the object ID of the table that caused the trigger invocation.

TG\_RELNAME

Data type `name`; the name of the table that caused the trigger invocation. This is now deprecated, and could disappear in a future release. Use `TG_TABLE_NAME` instead.

TG\_TABLE\_NAME

Data type `name`; the name of the table that caused the trigger invocation.

TG\_TABLE\_SCHEMA

Data type `name`; the name of the schema of the table that caused the trigger invocation.

TG\_NARGS

Data type `integer`; the number of arguments given to the trigger procedure in the `CREATE TRIGGER` statement.

TG\_ARGV[]

Data type array of `text`; the arguments from the `CREATE TRIGGER` statement. The index counts from 0. Invalid indices (less than 0 or greater than or equal to `tg_nargs`) result in a null value.

A trigger function must return either `NULL` or a record/row value having exactly the structure of the table the trigger was fired for.

Row-level triggers fired `BEFORE` can return null to signal the trigger manager to skip the rest of the operation for this row (i.e., subsequent triggers are not fired, and the `INSERT/UPDATE/DELETE` does not occur for this row). If a nonnull value is returned then the operation proceeds with that row value. Returning a row value different from the original value of `NEW` alters the row that will be inserted or updated (but has no direct effect in the `DELETE` case). To alter the row to be stored, it is possible to replace single values directly in `NEW` and return the modified `NEW`, or to build a complete new record/row to return.

The return value of a `BEFORE` or `AFTER` statement-level trigger or an `AFTER` row-level trigger is always ignored; it might as well be null. However, any of these types of triggers might still abort the entire operation by raising an error.

Example 38-2 shows an example of a trigger procedure in PL/pgSQL.

### Example 38-2. A PL/pgSQL Trigger Procedure

This example trigger ensures that any time a row is inserted or updated in the table, the current user name and time are stamped into the row. And it checks that an employee's name is given and that the salary is a positive value.

```
CREATE TABLE emp (
    empname text,
    salary integer,
    last_date timestamp,
    last_user text
);

CREATE FUNCTION emp_stamp() RETURNS trigger AS $emp_stamp$
```

```

BEGIN
    -- Check that empname and salary are given
    IF NEW.empname IS NULL THEN
        RAISE EXCEPTION 'empname cannot be null';
    END IF;
    IF NEW.salary IS NULL THEN
        RAISE EXCEPTION '% cannot have null salary', NEW.empname;
    END IF;

    -- Who works for us when she must pay for it?
    IF NEW.salary < 0 THEN
        RAISE EXCEPTION '% cannot have a negative salary', NEW.empname;
    END IF;

    -- Remember who changed the payroll when
    NEW.last_date := current_timestamp;
    NEW.last_user := current_user;
    RETURN NEW;
END;
$emp_stamp$ LANGUAGE plpgsql;

CREATE TRIGGER emp_stamp BEFORE INSERT OR UPDATE ON emp
    FOR EACH ROW EXECUTE PROCEDURE emp_stamp();

```

Another way to log changes to a table involves creating a new table that holds a row for each insert, update, or delete that occurs. This approach can be thought of as auditing changes to a table. Example 38-3 shows an example of an audit trigger procedure in PL/pgSQL.

### Example 38-3. A PL/pgSQL Trigger Procedure For Auditing

This example trigger ensures that any insert, update or delete of a row in the `emp` table is recorded (i.e., audited) in the `emp_audit` table. The current time and user name are stamped into the row, together with the type of operation performed on it.

```

CREATE TABLE emp (
    empname      text NOT NULL,
    salary       integer
);

CREATE TABLE emp_audit(
    operation     char(1)  NOT NULL,
    stamp         timestamp NOT NULL,
    userid        text     NOT NULL,
    empname       text     NOT NULL,
    salary integer
);

CREATE OR REPLACE FUNCTION process_emp_audit() RETURNS TRIGGER AS $emp_audit$
BEGIN
    --
    -- Create a row in emp_audit to reflect the operation performed on emp,
    -- make use of the special variable TG_OP to work out the operation.
    --

```

```

        IF (TG_OP = 'DELETE') THEN
            INSERT INTO emp_audit SELECT 'D', now(), user, OLD.*;
            RETURN OLD;
        ELSIF (TG_OP = 'UPDATE') THEN
            INSERT INTO emp_audit SELECT 'U', now(), user, NEW.*;
            RETURN NEW;
        ELSIF (TG_OP = 'INSERT') THEN
            INSERT INTO emp_audit SELECT 'I', now(), user, NEW.*;
            RETURN NEW;
        END IF;
        RETURN NULL; -- result is ignored since this is an AFTER trigger
    END;
$emp_audit$ LANGUAGE plpgsql;

CREATE TRIGGER emp_audit
AFTER INSERT OR UPDATE OR DELETE ON emp
    FOR EACH ROW EXECUTE PROCEDURE process_emp_audit();

```

One use of triggers is to maintain a summary table of another table. The resulting summary can be used in place of the original table for certain queries — often with vastly reduced run times. This technique is commonly used in Data Warehousing, where the tables of measured or observed data (called fact tables) might be extremely large. Example 38-4 shows an example of a trigger procedure in PL/pgSQL that maintains a summary table for a fact table in a data warehouse.

#### Example 38-4. A PL/pgSQL Trigger Procedure For Maintaining A Summary Table

The schema detailed here is partly based on the *Grocery Store* example from *The Data Warehouse Toolkit* by Ralph Kimball.

```

--
-- Main tables - time dimension and sales fact.
--
CREATE TABLE time_dimension (
    time_key          integer NOT NULL,
    day_of_week       integer NOT NULL,
    day_of_month      integer NOT NULL,
    month             integer NOT NULL,
    quarter           integer NOT NULL,
    year              integer NOT NULL
);
CREATE UNIQUE INDEX time_dimension_key ON time_dimension(time_key);

CREATE TABLE sales_fact (
    time_key          integer NOT NULL,
    product_key       integer NOT NULL,
    store_key         integer NOT NULL,
    amount_sold       numeric(12,2) NOT NULL,
    units_sold        integer NOT NULL,
    amount_cost       numeric(12,2) NOT NULL
);
CREATE INDEX sales_fact_time ON sales_fact(time_key);
--

```

```

-- Summary table - sales by time.
--
CREATE TABLE sales_summary_bytime (
    time_key                integer NOT NULL,
    amount_sold             numeric(15,2) NOT NULL,
    units_sold              numeric(12) NOT NULL,
    amount_cost             numeric(15,2) NOT NULL
);
CREATE UNIQUE INDEX sales_summary_bytime_key ON sales_summary_bytime(time_key);

--
-- Function and trigger to amend summarized column(s) on UPDATE, INSERT, DELETE.
--
CREATE OR REPLACE FUNCTION maint_sales_summary_bytime() RETURNS TRIGGER AS $maint_sales_sum
    DECLARE
        delta_time_key        integer;
        delta_amount_sold     numeric(15,2);
        delta_units_sold      numeric(12);
        delta_amount_cost     numeric(15,2);
    BEGIN

        -- Work out the increment/decrement amount(s).
        IF (TG_OP = 'DELETE') THEN

            delta_time_key = OLD.time_key;
            delta_amount_sold = -1 * OLD.amount_sold;
            delta_units_sold = -1 * OLD.units_sold;
            delta_amount_cost = -1 * OLD.amount_cost;

        ELSIF (TG_OP = 'UPDATE') THEN

            -- forbid updates that change the time_key -
            -- (probably not too onerous, as DELETE + INSERT is how most
            -- changes will be made).
            IF ( OLD.time_key != NEW.time_key) THEN
                RAISE EXCEPTION 'Update of time_key : % -> % not allowed', OLD.time_key, NEW.time_key;
            END IF;

            delta_time_key = OLD.time_key;
            delta_amount_sold = NEW.amount_sold - OLD.amount_sold;
            delta_units_sold = NEW.units_sold - OLD.units_sold;
            delta_amount_cost = NEW.amount_cost - OLD.amount_cost;

        ELSIF (TG_OP = 'INSERT') THEN

            delta_time_key = NEW.time_key;
            delta_amount_sold = NEW.amount_sold;
            delta_units_sold = NEW.units_sold;
            delta_amount_cost = NEW.amount_cost;

        END IF;
    
```

```

-- Insert or update the summary row with the new values.
<<insert_update>>
LOOP
    UPDATE sales_summary_bytime
        SET amount_sold = amount_sold + delta_amount_sold,
            units_sold = units_sold + delta_units_sold,
            amount_cost = amount_cost + delta_amount_cost
        WHERE time_key = delta_time_key;

    EXIT insert_update WHEN found;

BEGIN
    INSERT INTO sales_summary_bytime (
        time_key,
        amount_sold,
        units_sold,
        amount_cost)
        VALUES (
            delta_time_key,
            delta_amount_sold,
            delta_units_sold,
            delta_amount_cost
        );

    EXIT insert_update;

EXCEPTION
    WHEN UNIQUE_VIOLATION THEN
        -- do nothing
END;
END LOOP insert_update;

RETURN NULL;

END;
$maint_sales_summary_bytime$ LANGUAGE plpgsql;

CREATE TRIGGER maint_sales_summary_bytime
AFTER INSERT OR UPDATE OR DELETE ON sales_fact
    FOR EACH ROW EXECUTE PROCEDURE maint_sales_summary_bytime();

INSERT INTO sales_fact VALUES(1,1,1,10,3,15);
INSERT INTO sales_fact VALUES(1,2,1,20,5,35);
INSERT INTO sales_fact VALUES(2,2,1,40,15,135);
INSERT INTO sales_fact VALUES(2,3,1,10,1,13);
SELECT * FROM sales_summary_bytime;
DELETE FROM sales_fact WHERE product_key = 1;
SELECT * FROM sales_summary_bytime;
UPDATE sales_fact SET units_sold = units_sold * 2;
SELECT * FROM sales_summary_bytime;

```

## 38.10. PL/pgSQL Under the Hood

This section discusses some implementation details that are frequently important for PL/pgSQL users to know.

### 38.10.1. Variable Substitution

When PL/pgSQL prepares a SQL statement or expression for execution, any PL/pgSQL variable name appearing in the statement or expression is replaced by a parameter symbol,  $\$n$ . The current value of the variable is then provided as the value for the parameter whenever the statement or expression is executed. As an example, consider the function

```
CREATE FUNCTION logfunc(logtxt text) RETURNS void AS $$
    DECLARE
        curtime timestamp := now();
    BEGIN
        INSERT INTO logtable VALUES (logtxt, curtime);
    END;
$$ LANGUAGE plpgsql;
```

The INSERT statement will effectively be processed as

```
PREPARE statement_name(text, timestamp) AS
    INSERT INTO logtable VALUES ($1, $2);
```

followed on each execution by EXECUTE with the current actual values of the two variables. (Note: here we are speaking of the main SQL engine's EXECUTE command, not PL/pgSQL's EXECUTE.)

*The substitution mechanism will replace any token that matches a known variable's name.* This poses various traps for the unwary. For example, it is a bad idea to use a variable name that is the same as any table or column name that you need to reference in queries within the function, because what you think is a table or column name will still get replaced. In the above example, suppose that logtable has column names logtxt and logtime, and we try to write the INSERT as

```
INSERT INTO logtable (logtxt, logtime) VALUES (logtxt, curtime);
```

This will be fed to the main SQL parser as

```
INSERT INTO logtable ($1, logtime) VALUES ($1, $2);
```

resulting in a syntax error like this:

```
ERROR:  syntax error at or near "$1"
LINE 1: INSERT INTO logtable ( $1 , logtime) VALUES ( $1 ,  $2 )
                        ^
QUERY:  INSERT INTO logtable ( $1 , logtime) VALUES ( $1 ,  $2 )
CONTEXT:  SQL statement in PL/PgSQL function "logfunc2" near line 5
```

This example is fairly easy to diagnose, since it leads to an obvious syntax error. Much nastier are cases where the substitution is syntactically permissible, since the only symptom may be misbehavior of the function. In one case, a user wrote something like this:

```
DECLARE
    val text;
    search_key integer;
BEGIN
    ...
    FOR val IN SELECT val FROM table WHERE key = search_key LOOP ...
```

and wondered why all his table entries seemed to be NULL. Of course what happened here was that the query became

```
SELECT $1 FROM table WHERE key = $2
```

and thus it was just an expensive way of assigning `val`'s current value back to itself for each row.

A commonly used coding rule for avoiding such traps is to use a different naming convention for PL/pgSQL variables than you use for table and column names. For example, if all your variables are named `v_something` while none of your table or column names start with `v_`, you're pretty safe.

Another workaround is to use qualified (dotted) names for SQL entities. For instance we could safely have written the above example as

```
FOR val IN SELECT table.val FROM table WHERE key = search_key LOOP ...
```

because PL/pgSQL will not substitute a variable for a trailing component of a qualified name. However this solution does not work in every case — you can't qualify a name in an `INSERT`'s column name list, for instance. Another point is that record and row variable names will be matched to the first components of qualified names, so a qualified SQL name is still vulnerable in some cases. In such cases choosing a non-conflicting variable name is the only way.

Another technique you can use is to attach a label to the block in which your variables are declared, and then qualify the variable names in your SQL commands (see Section 38.2). For example,

```
<<pl>>
DECLARE
    val text;
BEGIN
    ...
    UPDATE table SET col = pl.val WHERE ...
```

This is not in itself a solution to the problem of conflicts, since an unqualified name in a SQL command is still at risk of being interpreted the “wrong” way. But it is useful for clarifying the intent of potentially-ambiguous code.

Variable substitution does not happen in the command string given to `EXECUTE` or one of its variants. If you need to insert a varying value into such a command, do so as part of constructing the string value, as illustrated in Section 38.5.4.

Variable substitution currently works only in `SELECT`, `INSERT`, `UPDATE`, and `DELETE` commands, because the main SQL engine allows parameter symbols only in these commands. To use a non-constant name

or value in other statement types (generically called utility statements), you must construct the utility statement as a string and `EXECUTE` it.

### 38.10.2. Plan Caching

The PL/pgSQL interpreter parses the function's source text and produces an internal binary instruction tree the first time the function is called (within each session). The instruction tree fully translates the PL/pgSQL statement structure, but individual SQL expressions and SQL commands used in the function are not translated immediately.

As each expression and SQL command is first executed in the function, the PL/pgSQL interpreter creates a prepared execution plan (using the SPI manager's `SPI_prepare` and `SPI_saveplan` functions). Subsequent visits to that expression or command reuse the prepared plan. Thus, a function with conditional code that contains many statements for which execution plans might be required will only prepare and save those plans that are really used during the lifetime of the database connection. This can substantially reduce the total amount of time required to parse and generate execution plans for the statements in a PL/pgSQL function. A disadvantage is that errors in a specific expression or command cannot be detected until that part of the function is reached in execution. (Trivial syntax errors will be detected during the initial parsing pass, but anything deeper will not be detected until execution.)

Once PL/pgSQL has made an execution plan for a particular command in a function, it will reuse that plan for the life of the database connection. This is usually a win for performance, but it can cause some problems if you dynamically alter your database schema. For example:

```
CREATE FUNCTION populate() RETURNS integer AS $$
DECLARE
    -- declarations
BEGIN
    PERFORM my_function();
END;
$$ LANGUAGE plpgsql;
```

If you execute the above function, it will reference the OID for `my_function()` in the execution plan produced for the `PERFORM` statement. Later, if you drop and recreate `my_function()`, then `populate()` will not be able to find `my_function()` anymore. You would then have to start a new database session so that `populate()` will be compiled afresh, before it will work again. You can avoid this problem by using `CREATE OR REPLACE FUNCTION` when updating the definition of `my_function`, since when a function is “replaced”, its OID is not changed.

**Note:** In PostgreSQL 8.3 and later, saved plans will be replaced whenever any schema changes have occurred to any tables they reference. This eliminates one of the major disadvantages of saved plans. However, there is no such mechanism for function references, and thus the above example involving a reference to a deleted function is still valid.

Because PL/pgSQL saves execution plans in this way, SQL commands that appear directly in a PL/pgSQL function must refer to the same tables and columns on every execution; that is, you cannot use a parameter as the name of a table or column in an SQL command. To get around this restriction, you can construct dy-

namic commands using the PL/pgSQL `EXECUTE` statement — at the price of constructing a new execution plan on every execution.

Another important point is that the prepared plans are parameterized to allow the values of PL/pgSQL variables to change from one use to the next, as discussed in detail above. Sometimes this means that a plan is less efficient than it would be if generated for a specific variable value. As an example, consider

```
SELECT * INTO myrec FROM dictionary WHERE word LIKE search_term;
```

where `search_term` is a PL/pgSQL variable. The cached plan for this query will never use an index on `word`, since the planner cannot assume that the `LIKE` pattern will be left-anchored at run time. To use an index the query must be planned with a specific constant `LIKE` pattern provided. This is another situation where `EXECUTE` can be used to force a new plan to be generated for each execution.

The mutable nature of record variables presents another problem in this connection. When fields of a record variable are used in expressions or statements, the data types of the fields must not change from one call of the function to the next, since each expression will be planned using the data type that is present when the expression is first reached. `EXECUTE` can be used to get around this problem when necessary.

If the same function is used as a trigger for more than one table, PL/pgSQL prepares and caches plans independently for each such table — that is, there is a cache for each trigger function and table combination, not just for each function. This alleviates some of the problems with varying data types; for instance, a trigger function will be able to work successfully with a column named `key` even if it happens to have different types in different tables.

Likewise, functions having polymorphic argument types have a separate plan cache for each combination of actual argument types they have been invoked for, so that data type differences do not cause unexpected failures.

Plan caching can sometimes have surprising effects on the interpretation of time-sensitive values. For example there is a difference between what these two functions do:

```
CREATE FUNCTION logfunc1(logtxt text) RETURNS void AS $$
BEGIN
    INSERT INTO logtable VALUES (logtxt, 'now');
END;
$$ LANGUAGE plpgsql;
```

and:

```
CREATE FUNCTION logfunc2(logtxt text) RETURNS void AS $$
DECLARE
    curtime timestamp;
BEGIN
    curtime := 'now';
    INSERT INTO logtable VALUES (logtxt, curtime);
END;
$$ LANGUAGE plpgsql;
```

In the case of `logfunc1`, the PostgreSQL main parser knows when preparing the plan for the `INSERT` that the string `'now'` should be interpreted as `timestamp`, because the target column of `logtable` is of that type. Thus, `'now'` will be converted to a constant when the `INSERT` is planned, and then used

in all invocations of `logfunc1` during the lifetime of the session. Needless to say, this isn't what the programmer wanted.

In the case of `logfunc2`, the PostgreSQL main parser does not know what type `'now'` should become and therefore it returns a data value of type `text` containing the string `now`. During the ensuing assignment to the local variable `curtime`, the PL/pgSQL interpreter casts this string to the `timestamp` type by calling the `text_out` and `timestamp_in` functions for the conversion. So, the computed time stamp is updated on each execution as the programmer expects.

## 38.11. Tips for Developing in PL/pgSQL

One good way to develop in PL/pgSQL is to use the text editor of your choice to create your functions, and in another window, use `psql` to load and test those functions. If you are doing it this way, it is a good idea to write the function using `CREATE OR REPLACE FUNCTION`. That way you can just reload the file to update the function definition. For example:

```
CREATE OR REPLACE FUNCTION testfunc(integer) RETURNS integer AS $$
    ....
$$ LANGUAGE plpgsql;
```

While running `psql`, you can load or reload such a function definition file with:

```
\i filename.sql
```

and then immediately issue SQL commands to test the function.

Another good way to develop in PL/pgSQL is with a GUI database access tool that facilitates development in a procedural language. One example of such a tool is `pgAdmin`, although others exist. These tools often provide convenient features such as escaping single quotes and making it easier to recreate and debug functions.

### 38.11.1. Handling of Quotation Marks

The code of a PL/pgSQL function is specified in `CREATE FUNCTION` as a string literal. If you write the string literal in the ordinary way with surrounding single quotes, then any single quotes inside the function body must be doubled; likewise any backslashes must be doubled (assuming escape string syntax is used). Doubling quotes is at best tedious, and in more complicated cases the code can become downright incomprehensible, because you can easily find yourself needing half a dozen or more adjacent quote marks. It's recommended that you instead write the function body as a "dollar-quoted" string literal (see Section 4.1.2.2). In the dollar-quoting approach, you never double any quote marks, but instead take care to choose a different dollar-quoting delimiter for each level of nesting you need. For example, you might write the `CREATE FUNCTION` command as:

```
CREATE OR REPLACE FUNCTION testfunc(integer) RETURNS integer AS $PROC$
    ....
$PROC$ LANGUAGE plpgsql;
```

Within this, you might use quote marks for simple literal strings in SQL commands and \$\$ to delimit fragments of SQL commands that you are assembling as strings. If you need to quote text that includes \$\$, you could use \$Q\$, and so on.

The following chart shows what you have to do when writing quote marks without dollar quoting. It might be useful when translating pre-dollar quoting code into something more comprehensible.

#### 1 quotation mark

To begin and end the function body, for example:

```
CREATE FUNCTION foo() RETURNS integer AS '
    ....
' LANGUAGE plpgsql;
```

Anywhere within a single-quoted function body, quote marks *must* appear in pairs.

#### 2 quotation marks

For string literals inside the function body, for example:

```
a_output := "Blah";
SELECT * FROM users WHERE f_name="foobar";
```

In the dollar-quoting approach, you'd just write:

```
a_output := 'Blah';
SELECT * FROM users WHERE f_name='foobar';
```

which is exactly what the PL/pgSQL parser would see in either case.

#### 4 quotation marks

When you need a single quotation mark in a string constant inside the function body, for example:

```
a_output := a_output || " AND name LIKE ""foobar"" AND xyz"
```

The value actually appended to a\_output would be: AND name LIKE 'foobar' AND xyz.

In the dollar-quoting approach, you'd write:

```
a_output := a_output || $$ AND name LIKE 'foobar' AND xyz$$
```

being careful that any dollar-quote delimiters around this are not just \$\$.

#### 6 quotation marks

When a single quotation mark in a string inside the function body is adjacent to the end of that string constant, for example:

```
a_output := a_output || " AND name LIKE ""foobar""
```

The value appended to a\_output would then be: AND name LIKE 'foobar'.

In the dollar-quoting approach, this becomes:

```
a_output := a_output || $$ AND name LIKE 'foobar'$$
```

#### 10 quotation marks

When you want two single quotation marks in a string constant (which accounts for 8 quotation marks) and this is adjacent to the end of that string constant (2 more). You will probably only need that if you are writing a function that generates other functions, as in Example 38-6. For example:

```
a_output := a_output || " if v_" ||
referrer_keys.kind || " like """"
|| referrer_keys.key_string || """"
then return """" || referrer_keys.referrer_type
```

```
|| """; end if;";
```

The value of `a_output` would then be:

```
if v_... like "..." then return "..."; end if;
```

In the dollar-quoting approach, this becomes:

```
a_output := a_output || $$ if v_$$ || referrer_keys.kind || $$ like '$$
|| referrer_keys.key_string || $$'
then return '$$ || referrer_keys.referrer_type
|| $$'; end if;$$;
```

where we assume we only need to put single quote marks into `a_output`, because it will be re-quoted before use.

## 38.12. Porting from Oracle PL/SQL

This section explains differences between PostgreSQL's PL/pgSQL language and Oracle's PL/SQL language, to help developers who port applications from Oracle® to PostgreSQL.

PL/pgSQL is similar to PL/SQL in many aspects. It is a block-structured, imperative language, and all variables have to be declared. Assignments, loops, conditionals are similar. The main differences you should keep in mind when porting from PL/SQL to PL/pgSQL are:

- There are no default values for parameters in PostgreSQL.
- You can overload function names in PostgreSQL. This is often used to work around the lack of default parameters.
- If a name used in a SQL command could be either a column name of a table or a reference to a variable of the function, PL/SQL treats it as a column name, while PL/pgSQL treats it as a variable name. It's best to avoid such ambiguities in the first place, but if necessary you can fix them by properly qualifying the ambiguous name. (See Section 38.10.1.)
- No need for cursors in PL/pgSQL, just put the query in the `FOR` statement. (See Example 38-6.)
- In PostgreSQL the function body must be written as a string literal. Therefore you need to use dollar quoting or escape single quotes in the function body. (See Section 38.11.1.)
- Instead of packages, use schemas to organize your functions into groups.
- Since there are no packages, there are no package-level variables either. This is somewhat annoying. You can keep per-session state in temporary tables instead.
- Integer `FOR` loops with `REVERSE` work differently: PL/SQL counts down from the second number to the first, while PL/pgSQL counts down from the first number to the second, requiring the loop bounds to be swapped when porting. This incompatibility is unfortunate but is unlikely to be changed. (See Section 38.6.3.5.)

### 38.12.1. Porting Examples

Example 38-5 shows how to port a simple function from PL/SQL to PL/pgSQL.

**Example 38-5. Porting a Simple Function from PL/SQL to PL/pgSQL**

Here is an Oracle PL/SQL function:

```
CREATE OR REPLACE FUNCTION cs_fmt_browser_version(v_name varchar,
                                                  v_version varchar)
RETURN varchar IS
BEGIN
    IF v_version IS NULL THEN
        RETURN v_name;
    END IF;
    RETURN v_name || '/' || v_version;
END;
/
show errors;
```

Let's go through this function and see the differences compared to PL/pgSQL:

- The `RETURN` key word in the function prototype (not the function body) becomes `RETURNS` in PostgreSQL. Also, `IS` becomes `AS`, and you need to add a `LANGUAGE` clause because PL/pgSQL is not the only possible function language.
- In PostgreSQL, the function body is considered to be a string literal, so you need to use quote marks or dollar quotes around it. This substitutes for the terminating `/` in the Oracle approach.
- The `show errors` command does not exist in PostgreSQL, and is not needed since errors are reported automatically.

This is how this function would look when ported to PostgreSQL:

```
CREATE OR REPLACE FUNCTION cs_fmt_browser_version(v_name varchar,
                                                  v_version varchar)
RETURNS varchar AS $$
BEGIN
    IF v_version IS NULL THEN
        RETURN v_name;
    END IF;
    RETURN v_name || '/' || v_version;
END;
$$ LANGUAGE plpgsql;
```

Example 38-6 shows how to port a function that creates another function and how to handle the ensuing quoting problems.

**Example 38-6. Porting a Function that Creates Another Function from PL/SQL to PL/pgSQL**

The following procedure grabs rows from a `SELECT` statement and builds a large function with the results in `IF` statements, for the sake of efficiency. Notice particularly the differences in the cursor and the `FOR` loop.

This is the Oracle version:

```

CREATE OR REPLACE PROCEDURE cs_update_referrer_type_proc IS
    CURSOR referrer_keys IS
        SELECT * FROM cs_referrer_keys
        ORDER BY try_order;

    func_cmd VARCHAR(4000);
BEGIN
    func_cmd := 'CREATE OR REPLACE FUNCTION cs_find_referrer_type(v_host IN VARCHAR,
        v_domain IN VARCHAR, v_url IN VARCHAR) RETURN VARCHAR IS BEGIN';

    FOR referrer_key IN referrer_keys LOOP
        func_cmd := func_cmd ||
            ' IF v_' || referrer_key.kind
            || ' LIKE "' || referrer_key.key_string
            || '" THEN RETURN "' || referrer_key.referrer_type
            || '" ; END IF;';
    END LOOP;

    func_cmd := func_cmd || ' RETURN NULL; END;';

    EXECUTE IMMEDIATE func_cmd;
END;
/
show errors;

```

Here is how this function would end up in PostgreSQL:

```

CREATE OR REPLACE FUNCTION cs_update_referrer_type_proc() RETURNS void AS $func$
DECLARE
    referrer_key RECORD; -- declare a generic record to be used in a FOR
    func_body text;
    func_cmd text;
BEGIN
    func_body := 'BEGIN';

    -- Notice how we scan through the results of a query in a FOR loop
    -- using the FOR <record> construct.

    FOR referrer_key IN SELECT * FROM cs_referrer_keys ORDER BY try_order LOOP
        func_body := func_body ||
            ' IF v_' || referrer_key.kind
            || ' LIKE ' || quote_literal(referrer_key.key_string)
            || ' THEN RETURN ' || quote_literal(referrer_key.referrer_type)
            || ' ; END IF;';
    END LOOP;

    func_body := func_body || ' RETURN NULL; END;';

    func_cmd :=
        'CREATE OR REPLACE FUNCTION cs_find_referrer_type(v_host varchar,
            v_domain varchar,
            v_url varchar)

            RETURNS varchar AS '
        || quote_literal(func_body)

```

```

|| ' LANGUAGE plpgsql;' ;

EXECUTE func_cmd;
END;
$func$ LANGUAGE plpgsql;

```

Notice how the body of the function is built separately and passed through `quote_literal` to double any quote marks in it. This technique is needed because we cannot safely use dollar quoting for defining the new function: we do not know for sure what strings will be interpolated from the `referrer_key.key_string` field. (We are assuming here that `referrer_key.kind` can be trusted to always be `host`, `domain`, or `url`, but `referrer_key.key_string` might be anything, in particular it might contain dollar signs.) This function is actually an improvement on the Oracle original, because it will not generate broken code when `referrer_key.key_string` or `referrer_key.referrer_type` contain quote marks.

Example 38-7 shows how to port a function with `OUT` parameters and string manipulation. PostgreSQL does not have a built-in `instr` function, but you can create one using a combination of other functions. In Section 38.12.3 there is a PL/pgSQL implementation of `instr` that you can use to make your porting easier.

### Example 38-7. Porting a Procedure With String Manipulation and `OUT` Parameters from PL/SQL to PL/pgSQL

The following Oracle PL/SQL procedure is used to parse a URL and return several elements (host, path, and query).

This is the Oracle version:

```

CREATE OR REPLACE PROCEDURE cs_parse_url(
    v_url IN VARCHAR,
    v_host OUT VARCHAR, -- This will be passed back
    v_path OUT VARCHAR, -- This one too
    v_query OUT VARCHAR) -- And this one
IS
    a_pos1 INTEGER;
    a_pos2 INTEGER;
BEGIN
    v_host := NULL;
    v_path := NULL;
    v_query := NULL;
    a_pos1 := instr(v_url, '//');

    IF a_pos1 = 0 THEN
        RETURN;
    END IF;
    a_pos2 := instr(v_url, '/', a_pos1 + 2);
    IF a_pos2 = 0 THEN
        v_host := substr(v_url, a_pos1 + 2);
        v_path := '/';
        RETURN;
    END IF;

```

```

v_host := substr(v_url, a_pos1 + 2, a_pos2 - a_pos1 - 2);
a_pos1 := instr(v_url, '?', a_pos2 + 1);

IF a_pos1 = 0 THEN
    v_path := substr(v_url, a_pos2);
    RETURN;
END IF;

v_path := substr(v_url, a_pos2, a_pos1 - a_pos2);
v_query := substr(v_url, a_pos1 + 1);
END;
/
show errors;

```

Here is a possible translation into PL/pgSQL:

```

CREATE OR REPLACE FUNCTION cs_parse_url(
    v_url IN VARCHAR,
    v_host OUT VARCHAR, -- This will be passed back
    v_path OUT VARCHAR, -- This one too
    v_query OUT VARCHAR) -- And this one
AS $$
DECLARE
    a_pos1 INTEGER;
    a_pos2 INTEGER;
BEGIN
    v_host := NULL;
    v_path := NULL;
    v_query := NULL;
    a_pos1 := instr(v_url, '//');

    IF a_pos1 = 0 THEN
        RETURN;
    END IF;
    a_pos2 := instr(v_url, '/', a_pos1 + 2);
    IF a_pos2 = 0 THEN
        v_host := substr(v_url, a_pos1 + 2);
        v_path := '/';
        RETURN;
    END IF;

    v_host := substr(v_url, a_pos1 + 2, a_pos2 - a_pos1 - 2);
    a_pos1 := instr(v_url, '?', a_pos2 + 1);

    IF a_pos1 = 0 THEN
        v_path := substr(v_url, a_pos2);
        RETURN;
    END IF;

    v_path := substr(v_url, a_pos2, a_pos1 - a_pos2);
    v_query := substr(v_url, a_pos1 + 1);
END;
$$ LANGUAGE plpgsql;

```

This function could be used like this:

```
SELECT * FROM cs_parse_url('http://foobar.com/query.cgi?baz');
```

Example 38-8 shows how to port a procedure that uses numerous features that are specific to Oracle.

### Example 38-8. Porting a Procedure from PL/SQL to PL/pgSQL

The Oracle version:

```
CREATE OR REPLACE PROCEDURE cs_create_job(v_job_id IN INTEGER) IS
    a_running_job_count INTEGER;
    PRAGMA AUTONOMOUS_TRANSACTION;❶
BEGIN
    LOCK TABLE cs_jobs IN EXCLUSIVE MODE;❷

    SELECT count(*) INTO a_running_job_count FROM cs_jobs WHERE end_stamp IS NULL;

    IF a_running_job_count > 0 THEN
        COMMIT; -- free lock❸
        raise_application_error(-20000, 'Unable to create a new job: a job is currently run
    END IF;

    DELETE FROM cs_active_job;
    INSERT INTO cs_active_job(job_id) VALUES (v_job_id);

    BEGIN
        INSERT INTO cs_jobs (job_id, start_stamp) VALUES (v_job_id, sysdate);
    EXCEPTION
        WHEN dup_val_on_index THEN NULL; -- don't worry if it already exists
    END;
    COMMIT;
END;
/
show errors
```

Procedures like this can easily be converted into PostgreSQL functions returning `void`. This procedure in particular is interesting because it can teach us some things:

- ❶ There is no `PRAGMA` statement in PostgreSQL.
- ❷ If you do a `LOCK TABLE` in PL/pgSQL, the lock will not be released until the calling transaction is finished.
- ❸ You cannot issue `COMMIT` in a PL/pgSQL function. The function is running within some outer transaction and so `COMMIT` would imply terminating the function's execution. However, in this particular case it is not necessary anyway, because the lock obtained by the `LOCK TABLE` will be released when we raise an error.

This is how we could port this procedure to PL/pgSQL:

```
CREATE OR REPLACE FUNCTION cs_create_job(v_job_id integer) RETURNS void AS $$
DECLARE
    a_running_job_count integer;
```

```

BEGIN
    LOCK TABLE cs_jobs IN EXCLUSIVE MODE;

    SELECT count(*) INTO a_running_job_count FROM cs_jobs WHERE end_stamp IS NULL;

    IF a_running_job_count > 0 THEN
        RAISE EXCEPTION 'Unable to create a new job: a job is currently running';❶
    END IF;

    DELETE FROM cs_active_job;
    INSERT INTO cs_active_job(job_id) VALUES (v_job_id);

    BEGIN
        INSERT INTO cs_jobs (job_id, start_stamp) VALUES (v_job_id, now());
    EXCEPTION
        WHEN unique_violation THEN ❷
            -- don't worry if it already exists
    END;
END;
$$ LANGUAGE plpgsql;

```

- ❶ The syntax of RAISE is considerably different from Oracle's similar statement.
- ❷ The exception names supported by PL/pgSQL are different from Oracle's. The set of built-in exception names is much larger (see Appendix A). There is not currently a way to declare user-defined exception names.

The main functional difference between this procedure and the Oracle equivalent is that the exclusive lock on the `cs_jobs` table will be held until the calling transaction completes. Also, if the caller later aborts (for example due to an error), the effects of this procedure will be rolled back.

## 38.12.2. Other Things to Watch For

This section explains a few other things to watch for when porting Oracle PL/SQL functions to PostgreSQL.

### 38.12.2.1. Implicit Rollback after Exceptions

In PL/pgSQL, when an exception is caught by an `EXCEPTION` clause, all database changes since the block's `BEGIN` are automatically rolled back. That is, the behavior is equivalent to what you'd get in Oracle with:

```

BEGIN
    SAVEPOINT s1;
    ... code here ...
EXCEPTION
    WHEN ... THEN
        ROLLBACK TO s1;
        ... code here ...
    WHEN ... THEN

```

```

        ROLLBACK TO s1;
        ... code here ...
    END;

```

If you are translating an Oracle procedure that uses `SAVEPOINT` and `ROLLBACK TO` in this style, your task is easy: just omit the `SAVEPOINT` and `ROLLBACK TO`. If you have a procedure that uses `SAVEPOINT` and `ROLLBACK TO` in a different way then some actual thought will be required.

### 38.12.2.2. EXECUTE

The PL/pgSQL version of `EXECUTE` works similarly to the PL/SQL version, but you have to remember to use `quote_literal` and `quote_ident` as described in Section 38.5.4. Constructs of the type `EXECUTE 'SELECT * FROM $1';` will not work reliably unless you use these functions.

### 38.12.2.3. Optimizing PL/pgSQL Functions

PostgreSQL gives you two function creation modifiers to optimize execution: “volatility” (whether the function always returns the same result when given the same arguments) and “strictness” (whether the function returns null if any argument is null). Consult the *CREATE FUNCTION* reference page for details.

When making use of these optimization attributes, your `CREATE FUNCTION` statement might look something like this:

```

CREATE FUNCTION foo(...) RETURNS integer AS $$
...
$$ LANGUAGE plpgsql STRICT IMMUTABLE;

```

## 38.12.3. Appendix

This section contains the code for a set of Oracle-compatible `instr` functions that you can use to simplify your porting efforts.

```

--
-- instr functions that mimic Oracle's counterpart
-- Syntax: instr(string1, string2, [n], [m]) where [] denotes optional parameters.
--
-- Searches string1 beginning at the nth character for the mth occurrence
-- of string2. If n is negative, search backwards. If m is not passed,
-- assume 1 (search starts at first character).
--

CREATE FUNCTION instr(vchar1, vchar2) RETURNS integer AS $$
DECLARE
    pos integer;

# Chapter 39. PL/Tcl - Tcl Procedural Language

PL/Tcl is a loadable procedural language for the PostgreSQL database system that enables the Tcl language<sup>1</sup> to be used to write functions and trigger procedures.

## 39.1. Overview

PL/Tcl offers most of the capabilities a function writer has in the C language, with a few restrictions, and with the addition of the powerful string processing libraries that are available for Tcl.

One compelling *good* restriction is that everything is executed from within the safety of the context of a Tcl interpreter. In addition to the limited command set of safe Tcl, only a few commands are available to access the database via SPI and to raise messages via `elog()`. PL/Tcl provides no way to access internals of the database server or to gain OS-level access under the permissions of the PostgreSQL server process, as a C function can do. Thus, unprivileged database users can be trusted to use this language; it does not give them unlimited authority.

The other notable implementation restriction is that Tcl functions cannot be used to create input/output functions for new data types.

Sometimes it is desirable to write Tcl functions that are not restricted to safe Tcl. For example, one might want a Tcl function that sends email. To handle these cases, there is a variant of PL/Tcl called `PL/TclU` (for untrusted Tcl). This is the exact same language except that a full Tcl interpreter is used. *If PL/TclU is used, it must be installed as an untrusted procedural language* so that only database superusers can create functions in it. The writer of a PL/TclU function must take care that the function cannot be used to do anything unwanted, since it will be able to do anything that could be done by a user logged in as the database administrator.

The shared object code for the PL/Tcl and PL/TclU call handlers is automatically built and installed in the PostgreSQL library directory if Tcl support is specified in the configuration step of the installation procedure. To install PL/Tcl and/or PL/TclU in a particular database, use the `createlang` program, for example `createlang pltcl dbname` or `createlang pltclu dbname`.

## 39.2. PL/Tcl Functions and Arguments

To create a function in the PL/Tcl language, use the standard *CREATE FUNCTION* syntax:

```
CREATE FUNCTION funcname (argument-types) RETURNS return-type AS $$
    # PL/Tcl function body
$$ LANGUAGE pltcl;
```

PL/TclU is the same, except that the language has to be specified as `pltclu`.

The body of the function is simply a piece of Tcl script. When the function is called, the argument values are passed as variables `$1 ... $n` to the Tcl script. The result is returned from the Tcl code in the usual way, with a `return` statement.

---

1. <http://www.tcl.tk/>

For example, a function returning the greater of two integer values could be defined as:

```
CREATE FUNCTION tcl_max(integer, integer) RETURNS integer AS $$
    if {$1 > $2} {return $1}
    return $2
$$ LANGUAGE pltcl STRICT;
```

Note the clause `STRICT`, which saves us from having to think about null input values: if a null value is passed, the function will not be called at all, but will just return a null result automatically.

In a nonstrict function, if the actual value of an argument is null, the corresponding  $\$n$  variable will be set to an empty string. To detect whether a particular argument is null, use the function `argisnull`. For example, suppose that we wanted `tcl_max` with one null and one nonnull argument to return the nonnull argument, rather than null:

```
CREATE FUNCTION tcl_max(integer, integer) RETURNS integer AS $$
    if {[argisnull 1]} {
        if {[argisnull 2]} { return_null }
        return $2
    }
    if {[argisnull 2]} { return $1 }
    if {$1 > $2} {return $1}
    return $2
$$ LANGUAGE pltcl;
```

As shown above, to return a null value from a PL/Tcl function, execute `return_null`. This can be done whether the function is strict or not.

Composite-type arguments are passed to the function as Tcl arrays. The element names of the array are the attribute names of the composite type. If an attribute in the passed row has the null value, it will not appear in the array. Here is an example:

```
CREATE TABLE employee (
    name text,
    salary integer,
    age integer
);

CREATE FUNCTION overpaid(employee) RETURNS boolean AS $$
    if {200000.0 < $1(salary)} {
        return "t"
    }
    if {$1(age) < 30 && 100000.0 < $1(salary)} {
        return "t"
    }
    return "f"
$$ LANGUAGE pltcl;
```

There is currently no support for returning a composite-type result value, nor for returning sets.

PL/Tcl does not currently have full support for domain types: it treats a domain the same as the underlying scalar type. This means that constraints associated with the domain will not be enforced. This is not an issue for function arguments, but it is a hazard if you declare a PL/Tcl function as returning a domain type.

### 39.3. Data Values in PL/Tcl

The argument values supplied to a PL/Tcl function's code are simply the input arguments converted to text form (just as if they had been displayed by a `SELECT` statement). Conversely, the `return` command will accept any string that is acceptable input format for the function's declared return type. So, within the PL/Tcl function, all values are just text strings.

### 39.4. Global Data in PL/Tcl

Sometimes it is useful to have some global data that is held between two calls to a function or is shared between different functions. This is easily done since all PL/Tcl functions executed in one session share the same safe Tcl interpreter. So, any global Tcl variable is accessible to all PL/Tcl function calls and will persist for the duration of the SQL session. (Note that PL/TclU functions likewise share global data, but they are in a different Tcl interpreter and cannot communicate with PL/Tcl functions.)

To help protect PL/Tcl functions from unintentionally interfering with each other, a global array is made available to each function via the `upvar` command. The global name of this variable is the function's internal name, and the local name is `GD`. It is recommended that `GD` be used for persistent private data of a function. Use regular Tcl global variables only for values that you specifically intend to be shared among multiple functions.

An example of using `GD` appears in the `spi_execp` example below.

### 39.5. Database Access from PL/Tcl

The following commands are available to access the database from the body of a PL/Tcl function:

```
spi_exec ?-count n? ?-array name? command ?loop-body?
```

Executes an SQL command given as a string. An error in the command causes an error to be raised. Otherwise, the return value of `spi_exec` is the number of rows processed (selected, inserted, updated, or deleted) by the command, or zero if the command is a utility statement. In addition, if the command is a `SELECT` statement, the values of the selected columns are placed in Tcl variables as described below.

The optional `-count` value tells `spi_exec` the maximum number of rows to process in the command. The effect of this is comparable to setting up a query as a cursor and then saying `FETCH n`.

If the command is a `SELECT` statement, the values of the result columns are placed into Tcl variables named after the columns. If the `-array` option is given, the column values are instead stored into the named associative array, with the column names used as array indexes.

If the command is a `SELECT` statement and no `loop-body` script is given, then only the first row of results are stored into Tcl variables; remaining rows, if any, are ignored. No storing occurs if the query returns no rows. (This case can be detected by checking the result of `spi_exec`.) For example:

```
spi_exec "SELECT count(*) AS cnt FROM pg_proc"
```

will set the Tcl variable `$cnt` to the number of rows in the `pg_proc` system catalog.

If the optional `loop-body` argument is given, it is a piece of Tcl script that is executed once for each row in the query result. (`loop-body` is ignored if the given command is not a `SELECT`.) The values of the current row's columns are stored into Tcl variables before each iteration. For example:

```
spi_exec -array C "SELECT * FROM pg_class" {
    elog DEBUG "have table $C(relname)"
}
```

will print a log message for every row of `pg_class`. This feature works similarly to other Tcl looping constructs; in particular `continue` and `break` work in the usual way inside the loop body.

If a column of a query result is null, the target variable for it is “unset” rather than being set.

`spi_prepare query typelist`

Prepares and saves a query plan for later execution. The saved plan will be retained for the life of the current session.

The query can use parameters, that is, placeholders for values to be supplied whenever the plan is actually executed. In the query string, refer to parameters by the symbols `$1 ... $n`. If the query uses parameters, the names of the parameter types must be given as a Tcl list. (Write an empty list for `typelist` if no parameters are used.)

The return value from `spi_prepare` is a query ID to be used in subsequent calls to `spi_execp`. See `spi_execp` for an example.

```
spi_execp ?-count n? ?-array name? ?-nulls string? queryid ?value-list?
?loop-body?
```

Executes a query previously prepared with `spi_prepare`. `queryid` is the ID returned by `spi_prepare`. If the query references parameters, a `value-list` must be supplied. This is a Tcl list of actual values for the parameters. The list must be the same length as the parameter type list previously given to `spi_prepare`. Omit `value-list` if the query has no parameters.

The optional value for `-nulls` is a string of spaces and ‘n’ characters telling `spi_execp` which of the parameters are null values. If given, it must have exactly the same length as the `value-list`. If it is not given, all the parameter values are nonnull.

Except for the way in which the query and its parameters are specified, `spi_execp` works just like `spi_exec`. The `-count`, `-array`, and `loop-body` options are the same, and so is the result value.

Here's an example of a PL/Tcl function using a prepared plan:

```
CREATE FUNCTION tl_count(integer, integer) RETURNS integer AS $$
    if {[ info exists GD(plan) ]} {
        # prepare the saved plan on the first call
        set GD(plan) [ spi_prepare \
            "SELECT count(*) AS cnt FROM tl WHERE num >= \ $1 AND num <= \ $2" \
```

```

        [ list int4 int4 ] ]
    }
    spi_execp -count 1 $GD(plan) [ list $1 $2 ]
    return $cnt
$$ LANGUAGE pltcl;

```

We need backslashes inside the query string given to `spi_prepare` to ensure that the `$n` markers will be passed through to `spi_prepare` as-is, and not replaced by Tcl variable substitution.

`spi_lastoid`

Returns the OID of the row inserted by the last `spi_exec` or `spi_execp`, if the command was a single-row `INSERT` and the modified table contained OIDs. (If not, you get zero.)

`quote string`

Doubles all occurrences of single quote and backslash characters in the given string. This can be used to safely quote strings that are to be inserted into SQL commands given to `spi_exec` or `spi_prepare`. For example, think about an SQL command string like:

```
"SELECT '$val' AS ret"
```

where the Tcl variable `val` actually contains `doesn't`. This would result in the final command string:

```
SELECT 'doesn't' AS ret
```

which would cause a parse error during `spi_exec` or `spi_prepare`. To work properly, the submitted command should contain:

```
SELECT 'doesn"t' AS ret
```

which can be formed in PL/Tcl using:

```
"SELECT '[ quote $val ]' AS ret"
```

One advantage of `spi_execp` is that you don't have to quote parameter values like this, since the parameters are never parsed as part of an SQL command string.

`elog level msg`

Emits a log or error message. Possible levels are `DEBUG`, `LOG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, and `FATAL`. `ERROR` raises an error condition; if this is not trapped by the surrounding Tcl code, the error propagates out to the calling query, causing the current transaction or subtransaction to be aborted. This is effectively the same as the Tcl `error` command. `FATAL` aborts the transaction and causes the current session to shut down. (There is probably no good reason to use this error level in PL/Tcl functions, but it's provided for completeness.) The other levels only generate messages of different priority levels. Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the `log_min_messages` and `client_min_messages` configuration variables. See Chapter 18 for more information.

## 39.6. Trigger Procedures in PL/Tcl

Trigger procedures can be written in PL/Tcl. PostgreSQL requires that a procedure that is to be called as a trigger must be declared as a function with no arguments and a return type of `trigger`.

The information from the trigger manager is passed to the procedure body in the following variables:

`$TG_name`

The name of the trigger from the `CREATE TRIGGER` statement.

`$TG_relid`

The object ID of the table that caused the trigger procedure to be invoked.

`$TG_table_name`

The name of the table that caused the trigger procedure to be invoked.

`$TG_table_schema`

The schema of the table that caused the trigger procedure to be invoked.

`$TG_relatts`

A Tcl list of the table column names, prefixed with an empty list element. So looking up a column name in the list with Tcl's `lsearch` command returns the element's number starting with 1 for the first column, the same way the columns are customarily numbered in PostgreSQL. (Empty list elements also appear in the positions of columns that have been dropped, so that the attribute numbering is correct for columns to their right.)

`$TG_when`

The string `BEFORE` or `AFTER` depending on the type of trigger call.

`$TG_level`

The string `ROW` or `STATEMENT` depending on the type of trigger call.

`$TG_op`

The string `INSERT`, `UPDATE`, or `DELETE` depending on the type of trigger call.

`$NEW`

An associative array containing the values of the new table row for `INSERT` or `UPDATE` actions, or empty for `DELETE`. The array is indexed by column name. Columns that are null will not appear in the array.

`$OLD`

An associative array containing the values of the old table row for `UPDATE` or `DELETE` actions, or empty for `INSERT`. The array is indexed by column name. Columns that are null will not appear in the array.

`$args`

A Tcl list of the arguments to the procedure as given in the `CREATE TRIGGER` statement. These arguments are also accessible as `$1 ... $n` in the procedure body.

The return value from a trigger procedure can be one of the strings `OK` or `SKIP`, or a list as returned by the `array get` Tcl command. If the return value is `OK`, the operation (`INSERT/UPDATE/DELETE`) that fired the trigger will proceed normally. `SKIP` tells the trigger manager to silently suppress the operation for this row. If a list is returned, it tells PL/Tcl to return a modified row to the trigger manager that will be inserted instead of the one given in `$NEW`. (This works for `INSERT` and `UPDATE` only.) Needless to say that all this is only meaningful when the trigger is `BEFORE` and `FOR EACH ROW`; otherwise the return value is ignored.

Here's a little example trigger procedure that forces an integer value in a table to keep track of the number of updates that are performed on the row. For new rows inserted, the value is initialized to 0 and then incremented on every update operation.

```
CREATE FUNCTION trigfunc_modcount() RETURNS trigger AS $$
    switch $TG_op {
        INSERT {
            set NEW($1) 0
        }
        UPDATE {
            set NEW($1) $OLD($1)
            incr NEW($1)
        }
        default {
            return OK
        }
    }
    return [array get NEW]
$$ LANGUAGE pltcl;

CREATE TABLE mytab (num integer, description text, modcnt integer);

CREATE TRIGGER trig_mytab_modcount BEFORE INSERT OR UPDATE ON mytab
    FOR EACH ROW EXECUTE PROCEDURE trigfunc_modcount('modcnt');
```

Notice that the trigger procedure itself does not know the column name; that's supplied from the trigger arguments. This lets the trigger procedure be reused with different tables.

## 39.7. Modules and the unknown command

PL/Tcl has support for autoloading Tcl code when used. It recognizes a special table, `pltcl_modules`, which is presumed to contain modules of Tcl code. If this table exists, the module `unknown` is fetched from the table and loaded into the Tcl interpreter immediately after creating the interpreter.

While the `unknown` module could actually contain any initialization script you need, it normally defines a Tcl `unknown` procedure that is invoked whenever Tcl does not recognize an invoked procedure name. PL/Tcl's standard version of this procedure tries to find a module in `pltcl_modules` that will define the required procedure. If one is found, it is loaded into the interpreter, and then execution is allowed to proceed with the originally attempted procedure call. A secondary table `pltcl_modfuncs` provides an index of which functions are defined by which modules, so that the lookup is reasonably quick.

The PostgreSQL distribution includes support scripts to maintain these tables: `pltcl_loadmod`, `pltcl_listmod`, `pltcl_delmod`, as well as source for the standard `unknown` module in `share/unknown.pltcl`. This module must be loaded into each database initially to support the autoloading mechanism.

The tables `pltcl_modules` and `pltcl_modfuncs` must be readable by all, but it is wise to make them owned and writable only by the database administrator.

## 39.8. Tcl Procedure Names

In PostgreSQL, the same function name can be used for different function definitions as long as the number of arguments or their types differ. Tcl, however, requires all procedure names to be distinct. PL/Tcl deals with this by making the internal Tcl procedure names contain the object ID of the function from the system table `pg_proc` as part of their name. Thus, PostgreSQL functions with the same name and different argument types will be different Tcl procedures, too. This is not normally a concern for a PL/Tcl programmer, but it might be visible when debugging.

# Chapter 40. PL/Perl - Perl Procedural Language

PL/Perl is a loadable procedural language that enables you to write PostgreSQL functions in the Perl programming language<sup>1</sup>.

The usual advantage to using PL/Perl is that this allows use, within stored functions, of the manifold “string munging” operators and functions available for Perl. Parsing complex strings might be easier using Perl than it is with the string functions and control structures provided in PL/pgSQL.

To install PL/Perl in a particular database, use `createlang plperl dbname`.

**Tip:** If a language is installed into `template1`, all subsequently created databases will have the language installed automatically.

**Note:** Users of source packages must specially enable the build of PL/Perl during the installation process. (Refer to Section 15.1 for more information.) Users of binary packages might find PL/Perl in a separate subpackage.

## 40.1. PL/Perl Functions and Arguments

To create a function in the PL/Perl language, use the standard *CREATE FUNCTION* syntax:

```
CREATE FUNCTION funcname (argument-types) RETURNS return-type AS $$  
    # PL/Perl function body  
$$ LANGUAGE plperl;
```

The body of the function is ordinary Perl code. In fact, the PL/Perl glue code wraps it inside a Perl subroutine. A PL/Perl function must always return a scalar value. You can return more complex structures (arrays, records, and sets) by returning a reference, as discussed below. Never return a list.

**Note:** The use of named nested subroutines is dangerous in Perl, especially if they refer to lexical variables in the enclosing scope. Because a PL/Perl function is wrapped in a subroutine, any named subroutine you create will be nested. In general, it is far safer to create anonymous subroutines which you call via a coderef. See the `perlfaq` man page for more details.

The syntax of the *CREATE FUNCTION* command requires the function body to be written as a string constant. It is usually most convenient to use dollar quoting (see Section 4.1.2.2) for the string constant. If you choose to use escape string syntax `E''`, you must double the single quote marks (`'`) and backslashes (`\`) used in the body of the function (see Section 4.1.2.1).

Arguments and results are handled as in any other Perl subroutine: arguments are passed in `@_`, and a result value is returned with `return` or as the last expression evaluated in the function.

For example, a function returning the greater of two integer values could be defined as:

---

1. <http://www.perl.com>

```
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
    if ($_[0] > $_[1]) { return $_[0]; }
    return $_[1];
$$ LANGUAGE plperl;
```

If an SQL null value is passed to a function, the argument value will appear as “undefined” in Perl. The above function definition will not behave very nicely with null inputs (in fact, it will act as though they are zeroes). We could add `STRICT` to the function definition to make PostgreSQL do something more reasonable: if a null value is passed, the function will not be called at all, but will just return a null result automatically. Alternatively, we could check for undefined inputs in the function body. For example, suppose that we wanted `perl_max` with one null and one nonnull argument to return the nonnull argument, rather than a null value:

```
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
    my ($x,$y) = @_;
    if (! defined $x) {
        if (! defined $y) { return undef; }
        return $y;
    }
    if (! defined $y) { return $x; }
    if ($x > $y) { return $x; }
    return $y;
$$ LANGUAGE plperl;
```

As shown above, to return an SQL null value from a PL/Perl function, return an undefined value. This can be done whether the function is strict or not.

Anything in a function argument that is not a reference is a string, which is in the standard PostgreSQL external text representation for the relevant data type. In the case of ordinary numeric or text types, Perl will just do the right thing and the programmer will normally not have to worry about it. However, in other cases the argument will need to be converted into a form that is more usable in Perl. For example, here is how to convert an argument of type `bytea` into unescaped binary data:

```
my $arg = shift;
$arg =~ s!\(?:\\|(\d{3}))!$1 ? chr(oct($1)) : "\\\"!ge;
```

Similarly, values passed back to PostgreSQL must be in the external text representation format. For example, here is how to escape binary data for a return value of type `bytea`:

```
$retval =~ s!(\\|[\^ -~])!sprintf("\\%03o",ord($1))!ge;
return $retval;
```

Perl can return PostgreSQL arrays as references to Perl arrays. Here is an example:

```
CREATE OR REPLACE function returns_array()
RETURNS text[][] AS $$
    return [['a"b','c,d'],['e\\f','g']];
$$ LANGUAGE plperl;
```

```
select returns_array();
```

Composite-type arguments are passed to the function as references to hashes. The keys of the hash are the attribute names of the composite type. Here is an example:

```
CREATE TABLE employee (
    name text,
    basesalary integer,
    bonus integer
);

CREATE FUNCTION empcomp(employee) RETURNS integer AS $$
    my ($emp) = @_;
    return $emp->{basesalary} + $emp->{bonus};
$$ LANGUAGE plperl;

SELECT name, empcomp(employee.*) FROM employee;
```

A PL/Perl function can return a composite-type result using the same approach: return a reference to a hash that has the required attributes. For example:

```
CREATE TYPE testrowperl AS (f1 integer, f2 text, f3 text);

CREATE OR REPLACE FUNCTION perl_row() RETURNS testrowperl AS $$
    return {f2 => 'hello', f1 => 1, f3 => 'world'};
$$ LANGUAGE plperl;

SELECT * FROM perl_row();
```

Any columns in the declared result data type that are not present in the hash will be returned as null values.

PL/Perl functions can also return sets of either scalar or composite types. Usually you'll want to return rows one at a time, both to speed up startup time and to keep from queueing up the entire result set in memory. You can do this with `return_next` as illustrated below. Note that after the last `return_next`, you must put either `return` or (better) `return undef`.

```
CREATE OR REPLACE FUNCTION perl_set_int(int)
RETURNS SETOF INTEGER AS $$
    foreach (0..$_[0]) {
        return_next($_);
    }
    return undef;
$$ LANGUAGE plperl;

SELECT * FROM perl_set_int(5);

CREATE OR REPLACE FUNCTION perl_set()
RETURNS SETOF testrowperl AS $$
    return_next({ f1 => 1, f2 => 'Hello', f3 => 'World' });
```

```

    return_next({ f1 => 2, f2 => 'Hello', f3 => 'PostgreSQL' });
    return_next({ f1 => 3, f2 => 'Hello', f3 => 'PL/Perl' });
    return undef;
$$ LANGUAGE plperl;

```

For small result sets, you can return a reference to an array that contains either scalars, references to arrays, or references to hashes for simple types, array types, and composite types, respectively. Here are some simple examples of returning the entire result set as an array reference:

```

CREATE OR REPLACE FUNCTION perl_set_int(int) RETURNS SETOF INTEGER AS $$
    return [0..$_[0]];
$$ LANGUAGE plperl;

SELECT * FROM perl_set_int(5);

CREATE OR REPLACE FUNCTION perl_set() RETURNS SETOF testrowperl AS $$
    return [
        { f1 => 1, f2 => 'Hello', f3 => 'World' },
        { f1 => 2, f2 => 'Hello', f3 => 'PostgreSQL' },
        { f1 => 3, f2 => 'Hello', f3 => 'PL/Perl' }
    ];
$$ LANGUAGE plperl;

SELECT * FROM perl_set();

```

If you wish to use the `strict` pragma with your code, the easiest way to do so is to `SET plperl.use_strict` to `true`. This parameter affects subsequent compilations of PL/Perl functions, but not functions already compiled in the current session. To set the parameter before PL/Perl has been loaded, it is necessary to have added “`plperl`” to the `custom_variable_classes` list in `postgresql.conf`.

Another way to use the `strict` pragma is to put:

```
use strict;
```

in the function body. But this only works in PL/PerlU functions, since `use` is not a trusted operation. In PL/Perl functions you can instead do:

```
BEGIN { strict->import(); }
```

## 40.2. Database Access from PL/Perl

Access to the database itself from your Perl function can be done via the function `spi_exec_query` described below, or via an experimental module `DBD::PgSPI2` (also available at CPAN mirror sites<sup>3</sup>). This

2. <http://www.cpan.org/modules/by-module/DBD/APILOS/>  
 3. <http://www.cpan.org/SITES.html>

module makes available a DBI-compliant database-handle named `$pg_dbh` that can be used to perform queries with normal DBI syntax.

PL/Perl provides additional Perl commands:

```
spi_exec_query(query [, max-rows])
spi_query(command)
spi_fetchrow(cursor)
spi_prepare(command, argument types)
spi_exec_prepared(plan)
spi_query_prepared(plan [, attributes], arguments)
spi_cursor_close(cursor)
spi_freeplan(plan)
```

`spi_exec_query` executes an SQL command and returns the entire row set as a reference to an array of hash references. *You should only use this command when you know that the result set will be relatively small.* Here is an example of a query (SELECT command) with the optional maximum number of rows:

```
$rv = spi_exec_query('SELECT * FROM my_table', 5);
```

This returns up to 5 rows from the table `my_table`. If `my_table` has a column `my_column`, you can get that value from row `$i` of the result like this:

```
$foo = $rv->{rows}[$i]->{my_column};
```

The total number of rows returned from a SELECT query can be accessed like this:

```
$nrows = $rv->{processed}
```

Here is an example using a different command type:

```
$query = "INSERT INTO my_table VALUES (1, 'test')";
```

```
$rv = spi_exec_query($query);
```

You can then access the command status (e.g., `SPI_OK_INSERT`) like this:

```
$res = $rv->{status};
```

To get the number of rows affected, do:

```
$nrows = $rv->{processed};
```

Here is a complete example:

```
CREATE TABLE test (
    i int,
    v varchar
);

INSERT INTO test (i, v) VALUES (1, 'first line');
INSERT INTO test (i, v) VALUES (2, 'second line');
INSERT INTO test (i, v) VALUES (3, 'third line');
INSERT INTO test (i, v) VALUES (4, 'immortal');

CREATE OR REPLACE FUNCTION test_munge() RETURNS SETOF test AS $$
    my $rv = spi_exec_query('select i, v from test;');
    my $status = $rv->{status};
    my $nrows = $rv->{processed};
    foreach my $rn (0 .. $nrows - 1) {
        my $row = $rv->{rows}[$rn];
```

```

    $row->{i} += 200 if defined($row->{i});
    $row->{v} =~ tr/A-Za-z/a-zA-Z/ if (defined($row->{v}));
    return_next($row);
}
return undef;
$$ LANGUAGE plperl;

```

```
SELECT * FROM test_munge();
```

`spi_query` and `spi_fetchrow` work together as a pair for row sets which might be large, or for cases where you wish to return rows as they arrive. `spi_fetchrow` works *only* with `spi_query`. The following example illustrates how you use them together:

```

CREATE TYPE foo_type AS (the_num INTEGER, the_text TEXT);

CREATE OR REPLACE FUNCTION lotsa_md5 (INTEGER) RETURNS SETOF foo_type AS $$
    use Digest::MD5 qw(md5_hex);
    my $file = '/usr/share/dict/words';
    my $t = localtime;
    elog(NOTICE, "opening file $file at $t" );
    open my $fh, '<', $file # ooh, it's a file access!
        or elog(ERROR, "cannot open $file for reading: $!");
    my @words = <$fh>;
    close $fh;
    $t = localtime;
    elog(NOTICE, "closed file $file at $t");
    chomp(@words);
    my $row;
    my $sth = spi_query("SELECT * FROM generate_series(1,$_[0]) AS b(a)");
    while (defined ($row = spi_fetchrow($sth))) {
        return_next({
            the_num => $row->{a},
            the_text => md5_hex($words[rand @words])
        });
    }
    return;
$$ LANGUAGE plperl;

SELECT * from lotsa_md5(500);

```

`spi_prepare`, `spi_query_prepared`, `spi_exec_prepared`, and `spi_freeplan` implement the same functionality but for prepared queries. Once a query plan is prepared by a call to `spi_prepare`, the plan can be used instead of the string query, either in `spi_exec_prepared`, where the result is the same as returned by `spi_exec_query`, or in `spi_query_prepared` which returns a cursor exactly as `spi_query` does, which can be later passed to `spi_fetchrow`.

The advantage of prepared queries is that it is possible to use one prepared plan for more than one query execution. After the plan is not needed anymore, it can be freed with `spi_freeplan`:

```

CREATE OR REPLACE FUNCTION init() RETURNS INTEGER AS $$
    $_SHARED{my_plan} = spi_prepare( 'SELECT (now() + $1)::date AS now', 'INTERVAL' );
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION add_time( INTERVAL ) RETURNS TEXT AS $$

```

```

        return spi_exec_prepared(
            $_SHARED{my_plan},
            $_[0],
        )->{rows}->[0]->{now};
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION done() RETURNS INTEGER AS $$
    spi_freeplan( $_SHARED{my_plan} );
    undef $_SHARED{my_plan};
$$ LANGUAGE plperl;

SELECT init();
SELECT add_time('1 day'), add_time('2 days'), add_time('3 days');
SELECT done();

    add_time | add_time | add_time
-----+-----+-----
2005-12-10 | 2005-12-11 | 2005-12-12

```

Note that the parameter subscript in `spi_prepare` is defined via `$1`, `$2`, `$3`, etc, so avoid declaring query strings in double quotes that might easily lead to hard-to-catch bugs.

Normally, `spi_fetchrow` should be repeated until it returns `undef`, indicating that there are no more rows to read. The cursor is automatically freed when `spi_fetchrow` returns `undef`. If you do not wish to read all the rows, instead call `spi_cursor_close` to free the cursor. Failure to do so will result in memory leaks.

`elog(level, msg)`

Emit a log or error message. Possible levels are `DEBUG`, `LOG`, `INFO`, `NOTICE`, `WARNING`, and `ERROR`. `ERROR` raises an error condition; if this is not trapped by the surrounding Perl code, the error propagates out to the calling query, causing the current transaction or subtransaction to be aborted. This is effectively the same as the Perl `die` command. The other levels only generate messages of different priority levels. Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the `log_min_messages` and `client_min_messages` configuration variables. See Chapter 18 for more information.

## 40.3. Data Values in PL/Perl

The argument values supplied to a PL/Perl function's code are simply the input arguments converted to text form (just as if they had been displayed by a `SELECT` statement). Conversely, the `return` command will accept any string that is acceptable input format for the function's declared return type. So, within the PL/Perl function, all values are just text strings.

## 40.4. Global Values in PL/Perl

You can use the global hash `%_SHARED` to store data, including code references, between function calls for the lifetime of the current session.

Here is a simple example for shared data:

```
CREATE OR REPLACE FUNCTION set_var(name text, val text) RETURNS text AS $$
    if ($_SHARED{$_[0]} = $_[1]) {
        return 'ok';
    } else {
        return "cannot set shared variable $_[0] to $_[1]";
    }
}
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION get_var(name text) RETURNS text AS $$
    return $_SHARED{$_[0]};
$$ LANGUAGE plperl;

SELECT set_var('sample', 'Hello, PL/Perl! How's tricks?');
SELECT get_var('sample');
```

Here is a slightly more complicated example using a code reference:

```
CREATE OR REPLACE FUNCTION myfuncs() RETURNS void AS $$
    $_SHARED{myquote} = sub {
        my $arg = shift;
        $arg =~ s/(['\\])/\\$1/g;
        return "'$arg'";
    };
$$ LANGUAGE plperl;

SELECT myfuncs(); /* initializes the function */

/* Set up a function that uses the quote function */

CREATE OR REPLACE FUNCTION use_quote(TEXT) RETURNS text AS $$
    my $text_to_quote = shift;
    my $qfunc = $_SHARED{myquote};
    return &$qfunc($text_to_quote);
$$ LANGUAGE plperl;
```

(You could have replaced the above with the one-liner `return $_SHARED{myquote}->($_[0]);` at the expense of readability.)

## 40.5. Trusted and Untrusted PL/Perl

Normally, PL/Perl is installed as a “trusted” programming language named `plperl`. In this setup, certain Perl operations are disabled to preserve security. In general, the operations that are restricted are those that interact with the environment. This includes file handle operations, `require`, and `use` (for external

modules). There is no way to access internals of the database server process or to gain OS-level access with the permissions of the server process, as a C function can do. Thus, any unprivileged database user can be permitted to use this language.

Here is an example of a function that will not work because file system operations are not allowed for security reasons:

```
CREATE FUNCTION badfunc() RETURNS integer AS $$
    my $tmpfile = "/tmp/badfile";
    open my $fh, '>', $tmpfile
        or elog(ERROR, qq{could not open the file "$tmpfile": $!});
    print $fh "Testing writing to a file\n";
    close $fh or elog(ERROR, qq{could not close the file "$tmpfile": $!});
    return 1;
$$ LANGUAGE plperl;
```

The creation of this function will fail as its use of a forbidden operation will be caught by the validator.

Sometimes it is desirable to write Perl functions that are not restricted. For example, one might want a Perl function that sends mail. To handle these cases, PL/Perl can also be installed as an “untrusted” language (usually called PL/PerlU). In this case the full Perl language is available. If the `createlang` program is used to install the language, the language name `plperlU` will select the untrusted PL/Perl variant.

The writer of a PL/PerlU function must take care that the function cannot be used to do anything unwanted, since it will be able to do anything that could be done by a user logged in as the database administrator. Note that the database system allows only database superusers to create functions in untrusted languages.

If the above function was created by a superuser using the language `plperlU`, execution would succeed.

**Note:** For security reasons, to stop a leak of privileged operations from PL/PerlU to PL/Perl, these two languages have to run in separate instances of the Perl interpreter. If your Perl installation has been appropriately compiled, this is not a problem. However, not all installations are compiled with the requisite flags. If PostgreSQL detects that this is the case then it will not start a second interpreter, but instead create an error. In consequence, in such an installation, you cannot use both PL/PerlU and PL/Perl in the same backend process. The remedy for this is to obtain a Perl installation created with the appropriate flags, namely either `usemultiplicity` or both `usethreads` and `useithreads`. For more details, see the `perlembed` manual page.

## 40.6. PL/Perl Triggers

PL/Perl can be used to write trigger functions. In a trigger function, the hash reference `$_TD` contains information about the current trigger event. `$_TD` is a global variable, which gets a separate local value for each invocation of the trigger. The fields of the `$_TD` hash reference are:

```
$_TD->{new} {foo}

NEW value of column foo
```

```
$_TD->{old}{foo}
```

OLD value of column `foo`

```
$_TD->{name}
```

Name of the trigger being called

```
$_TD->{event}
```

Trigger event: INSERT, UPDATE, DELETE, or UNKNOWN

```
$_TD->{when}
```

When the trigger was called: BEFORE, AFTER, or UNKNOWN

```
$_TD->{level}
```

The trigger level: ROW, STATEMENT, or UNKNOWN

```
$_TD->{relid}
```

OID of the table on which the trigger fired

```
$_TD->{table_name}
```

Name of the table on which the trigger fired

```
$_TD->{relname}
```

Name of the table on which the trigger fired. This has been deprecated, and could be removed in a future release. Please use `$_TD->{table_name}` instead.

```
$_TD->{table_schema}
```

Name of the schema in which the table on which the trigger fired, is

```
$_TD->{argc}
```

Number of arguments of the trigger function

```
@{$_TD->{args}}
```

Arguments of the trigger function. Does not exist if `$_TD->{argc}` is 0.

Triggers can return one of the following:

```
return;
```

Execute the statement

```
"SKIP"
```

Don't execute the statement

```
"MODIFY"
```

Indicates that the NEW row was modified by the trigger function

Here is an example of a trigger function, illustrating some of the above:

```
CREATE TABLE test (
  i int,
```

```

        v varchar
    );

CREATE OR REPLACE FUNCTION valid_id() RETURNS trigger AS $$
    if (($TD->{new}{i} >= 100) || ($TD->{new}{i} <= 0)) {
        return "SKIP";    # skip INSERT/UPDATE command
    } elsif ($TD->{new}{v} ne "immortal") {
        $TD->{new}{v} .= "(modified by trigger)";
        return "MODIFY";  # modify row and execute INSERT/UPDATE command
    } else {
        return;           # execute INSERT/UPDATE command
    }
$$ LANGUAGE plperl;

CREATE TRIGGER test_valid_id_trig
    BEFORE INSERT OR UPDATE ON test
    FOR EACH ROW EXECUTE PROCEDURE valid_id();

```

## 40.7. Limitations and Missing Features

The following features are currently missing from PL/Perl, but they would make welcome contributions.

- PL/Perl functions cannot call each other directly (because they are anonymous subroutines inside Perl).
- SPI is not yet fully implemented.
- If you are fetching very large data sets using `spi_exec_query`, you should be aware that these will all go into memory. You can avoid this by using `spi_query/spi_fetchrow` as illustrated earlier.

A similar problem occurs if a set-returning function passes a large set of rows back to PostgreSQL via `return`. You can avoid this problem too by instead using `return_next` for each row returned, as shown previously.

# Chapter 41. PL/Python - Python Procedural Language

The PL/Python procedural language allows PostgreSQL functions to be written in the Python language<sup>1</sup>.

To install PL/Python in a particular database, use `createlang plpythonu dbname`.

**Tip:** If a language is installed into `template1`, all subsequently created databases will have the language installed automatically.

As of PostgreSQL 7.4, PL/Python is only available as an “untrusted” language (meaning it does not offer any way of restricting what users can do in it). It has therefore been renamed to `plpythonu`. The trusted variant `plpython` might become available again in future, if a new secure execution mechanism is developed in Python.

**Note:** Users of source packages must specially enable the build of PL/Python during the installation process. (Refer to the installation instructions for more information.) Users of binary packages might find PL/Python in a separate subpackage.

## 41.1. PL/Python Functions

Functions in PL/Python are declared via the standard *CREATE FUNCTION* syntax:

```
CREATE FUNCTION funcname (argument-list)
    RETURNS return-type
AS $$
    # PL/Python function body
$$ LANGUAGE plpythonu;
```

The body of a function is simply a Python script. When the function is called, its arguments are passed as elements of the array `args[]`; named arguments are also passed as ordinary variables to the Python script. The result is returned from the Python code in the usual way, with `return` or `yield` (in case of a result-set statement).

For example, a function to return the greater of two integers can be defined as:

```
CREATE FUNCTION pymax (a integer, b integer)
    RETURNS integer
AS $$
    if a > b:
        return a
    return b
$$ LANGUAGE plpythonu;
```

---

1. <http://www.python.org>

The Python code that is given as the body of the function definition is transformed into a Python function. For example, the above results in:

```
def __plpython_procedure_pymax_23456():
    if a > b:
        return a
    return b
```

assuming that 23456 is the OID assigned to the function by PostgreSQL.

The PostgreSQL function parameters are available in the global `args` list. In the `pymax` example, `args[0]` contains whatever was passed in as the first argument and `args[1]` contains the second argument's value. Alternatively, one can use named parameters as shown in the example above. Use of named parameters is usually more readable.

If an SQL null value is passed to a function, the argument value will appear as `None` in Python. The above function definition will return the wrong answer for null inputs. We could add `STRICT` to the function definition to make PostgreSQL do something more reasonable: if a null value is passed, the function will not be called at all, but will just return a null result automatically. Alternatively, we could check for null inputs in the function body:

```
CREATE FUNCTION pymax (a integer, b integer)
    RETURNS integer
AS $$
    if (a is None) or (b is None):
        return None
    if a > b:
        return a
    return b
$$ LANGUAGE plpythonu;
```

As shown above, to return an SQL null value from a PL/Python function, return the value `None`. This can be done whether the function is strict or not.

Composite-type arguments are passed to the function as Python mappings. The element names of the mapping are the attribute names of the composite type. If an attribute in the passed row has the null value, it has the value `None` in the mapping. Here is an example:

```
CREATE TABLE employee (
    name text,
    salary integer,
    age integer
);

CREATE FUNCTION overpaid (e employee)
    RETURNS boolean
AS $$
    if e["salary"] > 200000:
        return True
    if (e["age"] < 30) and (e["salary"] > 100000):
        return True
    return False
$$ LANGUAGE plpythonu;
```

There are multiple ways to return row or composite types from a Python function. The following examples assume we have:

```
CREATE TYPE named_value AS (
    name    text,
    value   integer
);
```

A composite result can be returned as a:

Sequence type (a tuple or list, but not a set because it is not indexable)

Returned sequence objects must have the same number of items as the composite result type has fields. The item with index 0 is assigned to the first field of the composite type, 1 to the second and so on. For example:

```
CREATE FUNCTION make_pair (name text, value integer)
    RETURNS named_value
AS $$
    return [ name, value ]
    # or alternatively, as tuple: return ( name, value )
$$ LANGUAGE plpythonu;
```

To return a SQL null for any column, insert `None` at the corresponding position.

Mapping (dictionary)

The value for each result type column is retrieved from the mapping with the column name as key. Example:

```
CREATE FUNCTION make_pair (name text, value integer)
    RETURNS named_value
AS $$
    return { "name": name, "value": value }
$$ LANGUAGE plpythonu;
```

Any extra dictionary key/value pairs are ignored. Missing keys are treated as errors. To return a SQL null value for any column, insert `None` with the corresponding column name as the key.

Object (any object providing method `__getattr__`)

This works the same as a mapping. Example:

```
CREATE FUNCTION make_pair (name text, value integer)
    RETURNS named_value
AS $$
    class named_value:
        def __init__ (self, n, v):
            self.name = n
            self.value = v
    return named_value(name, value)

    # or simply
    class nv: pass
    nv.name = name
    nv.value = value
```

```

    return nv
$$ LANGUAGE plpythonu;

```

If you do not provide a return value, Python returns the default `None`. PL/Python translates Python's `None` into the SQL null value.

A PL/Python function can also return sets of scalar or composite types. There are several ways to achieve this because the returned object is internally turned into an iterator. The following examples assume we have composite type:

```

CREATE TYPE greeting AS (
    how text,
    who text
);

```

A set result can be returned from a:

Sequence type (tuple, list, set)

```

CREATE FUNCTION greet (how text)
    RETURNS SETOF greeting
AS $$
    # return tuple containing lists as composite types
    # all other combinations work also
    return ( [ how, "World" ], [ how, "PostgreSQL" ], [ how, "PL/Python" ] )
$$ LANGUAGE plpythonu;

```

Iterator (any object providing `__iter__` and `next` methods)

```

CREATE FUNCTION greet (how text)
    RETURNS SETOF greeting
AS $$
    class producer:
        def __init__ (self, how, who):
            self.how = how
            self.who = who
            self.ndx = -1

        def __iter__ (self):
            return self

        def next (self):
            self.ndx += 1
            if self.ndx == len(self.who):
                raise StopIteration
            return ( self.how, self.who[self.ndx] )

    return producer(how, [ "World", "PostgreSQL", "PL/Python" ])
$$ LANGUAGE plpythonu;

```

**Generator (yield)**

```
CREATE FUNCTION greet (how text)
  RETURNS SETOF greeting
AS $$
  for who in [ "World", "PostgreSQL", "PL/Python" ]:
    yield ( how, who )
$$ LANGUAGE plpythonu;
```

**Warning**

Currently, due to Python bug #1483133<sup>2</sup>, some debug versions of Python 2.4 (configured and compiled with option `--with-pydebug`) are known to crash the PostgreSQL server when using an iterator to return a set result. Unpatched versions of Fedora 4 contain this bug. It does not happen in production versions of Python or on patched versions of Fedora 4.

The global dictionary `SD` is available to store data between function calls. This variable is private static data. The global dictionary `GD` is public data, available to all Python functions within a session. Use with care.

Each function gets its own execution environment in the Python interpreter, so that global data and function arguments from `myfunc` are not available to `myfunc2`. The exception is the data in the `GD` dictionary, as mentioned above.

## 41.2. Trigger Functions

When a function is used as a trigger, the dictionary `TD` contains trigger-related values. The trigger rows are in `TD["new"]` and/or `TD["old"]` depending on the trigger event. `TD["event"]` contains the event as a string (INSERT, UPDATE, DELETE, or UNKNOWN). `TD["when"]` contains one of BEFORE, AFTER, and UNKNOWN. `TD["level"]` contains one of ROW, STATEMENT, and UNKNOWN. `TD["name"]` contains the trigger name, `TD["table_name"]` contains the name of the table on which the trigger occurred, `TD["table_schema"]` contains the schema of the table on which the trigger occurred, `TD["name"]` contains the trigger name, and `TD["relid"]` contains the OID of the table on which the trigger occurred. If the `CREATE TRIGGER` command included arguments, they are available in `TD["args"][0]` to `TD["args"][(n-1)]`.

If `TD["when"]` is BEFORE, you can return `None` or "OK" from the Python function to indicate the row is unmodified, "SKIP" to abort the event, or "MODIFY" to indicate you've modified the row.

## 41.3. Database Access

The PL/Python language module automatically imports a Python module called `plpy`. The functions and constants in this module are available to you in the Python code as `plpy.foo`. At present `plpy` implements the functions `plpy.debug(msg)`, `plpy.log(msg)`, `plpy.info(msg)`,

`plpy.notice(msg)`, `plpy.warning(msg)`, `plpy.error(msg)`, and `plpy.fatal(msg)`. `plpy.error` and `plpy.fatal` actually raise a Python exception which, if uncaught, propagates out to the calling query, causing the current transaction or subtransaction to be aborted. `raise plpy.ERROR(msg)` and `raise plpy.FATAL(msg)` are equivalent to calling `plpy.error` and `plpy.fatal`, respectively. The other functions only generate messages of different priority levels. Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the `log_min_messages` and `client_min_messages` configuration variables. See Chapter 18 for more information.

Additionally, the `plpy` module provides two functions called `execute` and `prepare`. Calling `plpy.execute` with a query string and an optional limit argument causes that query to be run and the result to be returned in a result object. The result object emulates a list or dictionary object. The result object can be accessed by row number and column name. It has these additional methods: `nrows` which returns the number of rows returned by the query, and `status` which is the `SPI_execute()` return value. The result object can be modified.

For example:

```
rv = plpy.execute("SELECT * FROM my_table", 5)
```

returns up to 5 rows from `my_table`. If `my_table` has a column `my_column`, it would be accessed as:

```
foo = rv[i]["my_column"]
```

The second function, `plpy.prepare`, prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query. For example:

```
plan = plpy.prepare("SELECT last_name FROM my_users WHERE first_name = $1", [ "text" ])
```

`text` is the type of the variable you will be passing for `$1`. After preparing a statement, you use the function `plpy.execute` to run it:

```
rv = plpy.execute(plan, [ "name" ], 5)
```

The third argument is the limit and is optional.

When you prepare a plan using the PL/Python module it is automatically saved. Read the SPI documentation (Chapter 42) for a description of what this means. In order to make effective use of this across function calls one needs to use one of the persistent storage dictionaries `SD` or `GD` (see Section 41.1). For example:

```
CREATE FUNCTION usesavedplan() RETURNS trigger AS $$
    if SD.has_key("plan"):
        plan = SD["plan"]
    else:
        plan = plpy.prepare("SELECT 1")
        SD["plan"] = plan
    # rest of function
$$ LANGUAGE plpythonu;
```

# Chapter 42. Server Programming Interface

The *Server Programming Interface* (SPI) gives writers of user-defined C functions the ability to run SQL commands inside their functions. SPI is a set of interface functions to simplify access to the parser, planner, and executor. SPI also does some memory management.

**Note:** The available procedural languages provide various means to execute SQL commands from procedures. Most of these facilities are based on SPI, so this documentation might be of use for users of those languages as well.

To avoid misunderstanding we'll use the term "function" when we speak of SPI interface functions and "procedure" for a user-defined C-function that is using SPI.

Note that if a command invoked via SPI fails, then control will not be returned to your procedure. Rather, the transaction or subtransaction in which your procedure executes will be rolled back. (This might seem surprising given that the SPI functions mostly have documented error-return conventions. Those conventions only apply for errors detected within the SPI functions themselves, however.) It is possible to recover control after an error by establishing your own subtransaction surrounding SPI calls that might fail. This is not currently documented because the mechanisms required are still in flux.

SPI functions return a nonnegative result on success (either via a returned integer value or in the global variable `SPI_result`, as described below). On error, a negative result or `NULL` will be returned.

Source code files that use SPI must include the header file `executor/spi.h`.

## 42.1. Interface Functions

### SPI\_connect

#### Name

`SPI_connect` — connect a procedure to the SPI manager

#### Synopsis

```
int SPI_connect(void)
```

#### Description

`SPI_connect` opens a connection from a procedure invocation to the SPI manager. You must call this function if you want to execute commands through SPI. Some utility SPI functions can be called from unconnected procedures.

If your procedure is already connected, `SPI_connect` will return the error code `SPI_ERROR_CONNECT`. This could happen if a procedure that has called `SPI_connect` directly calls another procedure that calls `SPI_connect`. While recursive calls to the SPI manager are permitted when an SQL command called through SPI invokes another function that uses SPI, directly nested calls to `SPI_connect` and `SPI_finish` are forbidden. (But see `SPI_push` and `SPI_pop`.)

## Return Value

`SPI_OK_CONNECT`

on success

`SPI_ERROR_CONNECT`

on error

# SPI\_finish

## Name

`SPI_finish` — disconnect a procedure from the SPI manager

## Synopsis

```
int SPI_finish(void)
```

## Description

`SPI_finish` closes an existing connection to the SPI manager. You must call this function after completing the SPI operations needed during your procedure's current invocation. You do not need to worry about making this happen, however, if you abort the transaction via `elog(ERROR)`. In that case SPI will clean itself up automatically.

If `SPI_finish` is called without having a valid connection, it will return `SPI_ERROR_UNCONNECTED`. There is no fundamental problem with this; it means that the SPI manager has nothing to do.

## Return Value

`SPI_OK_FINISH`

if properly disconnected

`SPI_ERROR_UNCONNECTED`

if called from an unconnected procedure

# SPI\_push

## Name

`SPI_push` — push SPI stack to allow recursive SPI usage

## Synopsis

```
void SPI_push(void)
```

## Description

`SPI_push` should be called before executing another procedure that might itself wish to use SPI. After `SPI_push`, SPI is no longer in a “connected” state, and SPI function calls will be rejected unless a fresh `SPI_connect` is done. This ensures a clean separation between your procedure’s SPI state and that of another procedure you call. After the other procedure returns, call `SPI_pop` to restore access to your own SPI state.

Note that `SPI_execute` and related functions automatically do the equivalent of `SPI_push` before passing control back to the SQL execution engine, so it is not necessary for you to worry about this when using those functions. Only when you are directly calling arbitrary code that might contain `SPI_connect` calls do you need to issue `SPI_push` and `SPI_pop`.

# SPI\_pop

## Name

SPI\_pop — pop SPI stack to return from recursive SPI usage

## Synopsis

```
void SPI_pop(void)
```

## Description

SPI\_pop pops the previous environment from the SPI call stack. See SPI\_push.

# SPI\_execute

## Name

SPI\_execute — execute a command

## Synopsis

```
int SPI_execute(const char * command, bool read_only, long count)
```

## Description

SPI\_execute executes the specified SQL command for `count` rows. If `read_only` is true, the command must be read-only, and execution overhead is somewhat reduced.

This function can only be called from a connected procedure.

If `count` is zero then the command is executed for all rows that it applies to. If `count` is greater than 0, then the number of rows for which the command will be executed is restricted (much like a `LIMIT` clause). For example:

```
SPI_execute("INSERT INTO foo SELECT * FROM bar", false, 5);
```

will allow at most 5 rows to be inserted into the table.

You can pass multiple commands in one string, but later commands cannot depend on the creation of objects earlier in the string, because the whole string will be parsed and planned before execution begins. SPI\_execute returns the result for the command executed last. The `count` limit applies to each command separately, but it is not applied to hidden commands generated by rules.

When `read_only` is false, SPI\_execute increments the command counter and computes a new *snapshot* before executing each command in the string. The snapshot does not actually change if the current transaction isolation level is `SERIALIZABLE`, but in `READ COMMITTED` mode the snapshot update allows each command to see the results of newly committed transactions from other sessions. This is essential for consistent behavior when the commands are modifying the database.

When `read_only` is true, SPI\_execute does not update either the snapshot or the command counter, and it allows only plain `SELECT` commands to appear in the command string. The commands are executed using the snapshot previously established for the surrounding query. This execution mode is somewhat faster than the read/write mode due to eliminating per-command overhead. It also allows genuinely *stable* functions to be built: since successive executions will all use the same snapshot, there will be no change in the results.

It is generally unwise to mix read-only and read-write commands within a single function using SPI; that could result in very confusing behavior, since the read-only queries would not see the results of any database updates done by the read-write queries.

The actual number of rows for which the (last) command was executed is returned in the global variable `SPI_processed`. If the return value of the function is `SPI_OK_SELECT`, `SPI_OK_INSERT_RETURNING`, `SPI_OK_DELETE_RETURNING`, or `SPI_OK_UPDATE_RETURNING`, then you can use the global pointer

SPI\_tupletable \*SPI\_tupletable to access the result rows. Some utility commands (such as EXPLAIN) also return row sets, and SPI\_tupletable will contain the result in these cases too.

The structure SPI\_tupletable is defined thus:

```
typedef struct
{
    MemoryContext tupabcxt;    /* memory context of result table */
    uint32         allocated;  /* number of allocated vals */
    uint32         free;       /* number of free vals */
    TupleDesc      tupdesc;    /* row descriptor */
    HeapTuple      *vals;      /* rows */
} SPI_tupletable;
```

vals is an array of pointers to rows. (The number of valid entries is given by SPI\_processed.) tupdesc is a row descriptor which you can pass to SPI functions dealing with rows. tupabcxt, allocated, and free are internal fields not intended for use by SPI callers.

SPI\_finish frees all SPI\_tupletables allocated during the current procedure. You can free a particular result table earlier, if you are done with it, by calling SPI\_freetupletable.

## Arguments

```
const char * command
    string containing command to execute

bool read_only
    true for read-only execution

long count
    maximum number of rows to process or return
```

## Return Value

If the execution of the command was successful then one of the following (nonnegative) values will be returned:

```
SPI_OK_SELECT
    if a SELECT (but not SELECT INTO) was executed

SPI_OK_SELINTO
    if a SELECT INTO was executed

SPI_OK_INSERT
    if an INSERT was executed

SPI_OK_DELETE
    if a DELETE was executed
```

SPI\_OK\_UPDATE

if an UPDATE was executed

SPI\_OK\_INSERT\_RETURNING

if an INSERT RETURNING was executed

SPI\_OK\_DELETE\_RETURNING

if a DELETE RETURNING was executed

SPI\_OK\_UPDATE\_RETURNING

if an UPDATE RETURNING was executed

SPI\_OK\_UTILITY

if a utility command (e.g., CREATE TABLE) was executed

On error, one of the following negative values is returned:

SPI\_ERROR\_ARGUMENT

if command is NULL or count is less than 0

SPI\_ERROR\_COPY

if COPY TO stdout or COPY FROM stdin was attempted

SPI\_ERROR\_TRANSACTION

if a transaction manipulation command was attempted (BEGIN, COMMIT, ROLLBACK, SAVEPOINT, PREPARE TRANSACTION, COMMIT PREPARED, ROLLBACK PREPARED, or any variant thereof)

SPI\_ERROR\_OPUNKNOWN

if the command type is unknown (shouldn't happen)

SPI\_ERROR\_UNCONNECTED

if called from an unconnected procedure

## Notes

The functions `SPI_execute`, `SPI_exec`, `SPI_execute_plan`, and `SPI_execp` change both `SPI_processed` and `SPI_tuptable` (just the pointer, not the contents of the structure). Save these two global variables into local procedure variables if you need to access the result table of `SPI_execute` or a related function across later calls.

# SPI\_exec

## Name

SPI\_exec — execute a read/write command

## Synopsis

```
int SPI_exec(const char * command, long count)
```

## Description

SPI\_exec is the same as SPI\_execute, with the latter's read\_only parameter always taken as false.

## Arguments

const char \* command

string containing command to execute

long count

maximum number of rows to process or return

## Return Value

See SPI\_execute.

# SPI\_prepare

## Name

`SPI_prepare` — prepare a plan for a command, without executing it yet

## Synopsis

```
SPIPlanPtr SPI_prepare(const char * command, int nargs, Oid * argtypes)
```

## Description

`SPI_prepare` creates and returns an execution plan for the specified command but doesn't execute the command. This function should only be called from a connected procedure.

When the same or a similar command is to be executed repeatedly, it might be advantageous to perform the planning only once. `SPI_prepare` converts a command string into an execution plan that can be executed repeatedly using `SPI_execute_plan`.

A prepared command can be generalized by writing parameters (\$1, \$2, etc.) in place of what would be constants in a normal command. The actual values of the parameters are then specified when `SPI_execute_plan` is called. This allows the prepared command to be used over a wider range of situations than would be possible without parameters.

The plan returned by `SPI_prepare` can be used only in the current invocation of the procedure, since `SPI_finish` frees memory allocated for a plan. But a plan can be saved for longer using the function `SPI_saveplan`.

## Arguments

`const char * command`

command string

`int nargs`

number of input parameters (\$1, \$2, etc.)

`Oid * argtypes`

pointer to an array containing the OIDs of the data types of the parameters

## Return Value

`SPI_prepare` returns a non-null pointer to an execution plan. On error, `NULL` will be returned, and `SPI_result` will be set to one of the same error codes used by `SPI_execute`, except that it is set to

`SPI_ERROR_ARGUMENT` if `command` is `NULL`, or if `nargs` is less than 0, or if `nargs` is greater than 0 and `argtypes` is `NULL`.

## Notes

`SPIPlanPtr` is declared as a pointer to an opaque struct type in `spi.h`. It is unwise to try to access its contents directly, as that makes your code much more likely to break in future revisions of PostgreSQL.

There is a disadvantage to using parameters: since the planner does not know the values that will be supplied for the parameters, it might make worse planning choices than it would make for a normal command with all constants visible.

# SPI\_prepare\_cursor

## Name

`SPI_prepare_cursor` — prepare a plan for a command, without executing it yet

## Synopsis

```
SPIPlanPtr SPI_prepare_cursor(const char * command, int nargs, Oid * argtypes, int cursorOptions)
```

## Description

`SPI_prepare_cursor` is identical to `SPI_prepare`, except that it also allows specification of the planner’s “cursor options” parameter. This is a bitmask having the values shown in `nodes/parsenodes.h` for the `options` field of `DeclareCursorStmt`. `SPI_prepare` always takes these options as zero.

## Arguments

```
const char * command
```

command string

```
int nargs
```

number of input parameters (\$1, \$2, etc.)

```
Oid * argtypes
```

pointer to an array containing the OIDs of the data types of the parameters

```
int cursorOptions
```

integer bitmask of cursor options; zero produces default behavior

## Return Value

`SPI_prepare_cursor` has the same return conventions as `SPI_prepare`.

## Notes

Useful bits to set in `cursorOptions` include `CURSOR_OPT_SCROLL`, `CURSOR_OPT_NO_SCROLL`, and `CURSOR_OPT_FAST_PLAN`. Note in particular that `CURSOR_OPT_HOLD` is ignored.

# SPI\_getargcount

## Name

`SPI_getargcount` — return the number of arguments needed by a plan prepared by `SPI_prepare`

## Synopsis

```
int SPI_getargcount(SPIPlanPtr plan)
```

## Description

`SPI_getargcount` returns the number of arguments needed to execute a plan prepared by `SPI_prepare`.

## Arguments

`SPIPlanPtr plan`  
execution plan (returned by `SPI_prepare`)

## Return Value

The count of expected arguments for the `plan`. If the `plan` is `NULL` or invalid, `SPI_result` is set to `SPI_ERROR_ARGUMENT` and `-1` is returned.

# SPI\_getargtypeid

## Name

`SPI_getargtypeid` — return the data type OID for an argument of a plan prepared by `SPI_prepare`

## Synopsis

```
Oid SPI_getargtypeid(SPIPlanPtr plan, int argIndex)
```

## Description

`SPI_getargtypeid` returns the OID representing the type id for the `argIndex`'th argument of a plan prepared by `SPI_prepare`. First argument is at index zero.

## Arguments

```
SPIPlanPtr plan
    execution plan (returned by SPI_prepare)

int argIndex
    zero based index of the argument
```

## Return Value

The type id of the argument at the given index. If the `plan` is `NULL` or invalid, or `argIndex` is less than 0 or not less than the number of arguments declared for the `plan`, `SPI_result` is set to `SPI_ERROR_ARGUMENT` and `InvalidOid` is returned.

# SPI\_is\_cursor\_plan

## Name

`SPI_is_cursor_plan` — return true if a plan prepared by `SPI_prepare` can be used with `SPI_cursor_open`

## Synopsis

```
bool SPI_is_cursor_plan(SPIPlanPtr plan)
```

## Description

`SPI_is_cursor_plan` returns true if a plan prepared by `SPI_prepare` can be passed as an argument to `SPI_cursor_open`, or false if that is not the case. The criteria are that the plan represents one single command and that this command returns tuples to the caller; for example, `SELECT` is allowed unless it contains an `INTO` clause, and `UPDATE` is allowed only if it contains a `RETURNING` clause.

## Arguments

`SPIPlanPtr plan`  
execution plan (returned by `SPI_prepare`)

## Return Value

true or false to indicate if the plan can produce a cursor or not, with `SPI_result` set to zero. If it is not possible to determine the answer (for example, if the plan is NULL or invalid, or if called when not connected to SPI), then `SPI_result` is set to a suitable error code and false is returned.

# SPI\_execute\_plan

## Name

`SPI_execute_plan` — execute a plan prepared by `SPI_prepare`

## Synopsis

```
int SPI_execute_plan(SPIPlanPtr plan, Datum * values, const char * nulls,  
                    bool read_only, long count)
```

## Description

`SPI_execute_plan` executes a plan prepared by `SPI_prepare`. `read_only` and `count` have the same interpretation as in `SPI_execute`.

## Arguments

`SPIPlanPtr plan`

execution plan (returned by `SPI_prepare`)

`Datum * values`

An array of actual parameter values. Must have same length as the plan's number of arguments.

`const char * nulls`

An array describing which parameters are null. Must have same length as the plan's number of arguments. `n` indicates a null value (entry in `values` will be ignored); a space indicates a nonnull value (entry in `values` is valid).

If `nulls` is `NULL` then `SPI_execute_plan` assumes that no parameters are null.

`bool read_only`

true for read-only execution

`long count`

maximum number of rows to process or return

## Return Value

The return value is the same as for `SPI_execute`, with the following additional possible error (negative) results:

`SPI_ERROR_ARGUMENT`

if `plan` is `NULL` or invalid, or `count` is less than 0

`SPI_ERROR_PARAM`

if `values` is `NULL` and `plan` was prepared with some parameters

`SPI_processed` and `SPI_tuptable` are set as in `SPI_execute` if successful.

## Notes

If one of the objects (a table, function, etc.) referenced by the prepared plan is dropped during the session then the result of `SPI_execute_plan` for this plan will be unpredictable.

# SPI\_execp

## Name

SPI\_execp — execute a plan in read/write mode

## Synopsis

```
int SPI_execp(SPIPlanPtr plan, Datum * values, const char * nulls, long count)
```

## Description

SPI\_execp is the same as SPI\_execute\_plan, with the latter's read\_only parameter always taken as false.

## Arguments

SPIPlanPtr plan

execution plan (returned by SPI\_prepare)

Datum \* values

An array of actual parameter values. Must have same length as the plan's number of arguments.

const char \* nulls

An array describing which parameters are null. Must have same length as the plan's number of arguments. n indicates a null value (entry in values will be ignored); a space indicates a nonnull value (entry in values is valid).

If nulls is NULL then SPI\_execp assumes that no parameters are null.

long count

maximum number of rows to process or return

## Return Value

See SPI\_execute\_plan.

SPI\_processed and SPI\_tuptable are set as in SPI\_execute if successful.

# SPI\_cursor\_open

## Name

`SPI_cursor_open` — set up a cursor using a plan created with `SPI_prepare`

## Synopsis

```
Portal SPI_cursor_open(const char * name, SPIPlanPtr plan,
                      Datum * values, const char * nulls,
                      bool read_only)
```

## Description

`SPI_cursor_open` sets up a cursor (internally, a portal) that will execute a plan prepared by `SPI_prepare`. The parameters have the same meanings as the corresponding parameters to `SPI_execute_plan`.

Using a cursor instead of executing the plan directly has two benefits. First, the result rows can be retrieved a few at a time, avoiding memory overrun for queries that return many rows. Second, a portal can outlive the current procedure (it can, in fact, live to the end of the current transaction). Returning the portal name to the procedure's caller provides a way of returning a row set as result.

The passed-in data will be copied into the cursor's portal, so it can be freed while the cursor still exists.

## Arguments

`const char * name`

name for portal, or `NULL` to let the system select a name

`SPIPlanPtr plan`

execution plan (returned by `SPI_prepare`)

`Datum * values`

An array of actual parameter values. Must have same length as the plan's number of arguments.

`const char * nulls`

An array describing which parameters are null. Must have same length as the plan's number of arguments. `n` indicates a null value (entry in `values` will be ignored); a space indicates a nonnull value (entry in `values` is valid).

If `nulls` is `NULL` then `SPI_cursor_open` assumes that no parameters are null.

`bool read_only`

true for read-only execution

## **Return Value**

Pointer to portal containing the cursor. Note there is no error return convention; any error will be reported via `elog`.

# SPI\_cursor\_find

## Name

`SPI_cursor_find` — find an existing cursor by name

## Synopsis

```
Portal SPI_cursor_find(const char * name)
```

## Description

`SPI_cursor_find` finds an existing portal by name. This is primarily useful to resolve a cursor name returned as text by some other function.

## Arguments

```
const char * name  
    name of the portal
```

## Return Value

pointer to the portal with the specified name, or `NULL` if none was found

# SPI\_cursor\_fetch

## Name

`SPI_cursor_fetch` — fetch some rows from a cursor

## Synopsis

```
void SPI_cursor_fetch(Portal portal, bool forward, long count)
```

## Description

`SPI_cursor_fetch` fetches some rows from a cursor. This is equivalent to a subset of the SQL command `FETCH` (see `SPI_scroll_cursor_fetch` for more functionality).

## Arguments

`Portal portal`

portal containing the cursor

`bool forward`

true for fetch forward, false for fetch backward

`long count`

maximum number of rows to fetch

## Return Value

`SPI_processed` and `SPI_tuptable` are set as in `SPI_execute` if successful.

## Notes

Fetching backward may fail if the cursor's plan was not created with the `CURSOR_OPT_SCROLL` option.

# SPI\_cursor\_move

## Name

`SPI_cursor_move` — move a cursor

## Synopsis

```
void SPI_cursor_move(Portal portal, bool forward, long count)
```

## Description

`SPI_cursor_move` skips over some number of rows in a cursor. This is equivalent to a subset of the SQL command `MOVE` (see `SPI_scroll_cursor_move` for more functionality).

## Arguments

`Portal portal`

portal containing the cursor

`bool forward`

true for move forward, false for move backward

`long count`

maximum number of rows to move

## Notes

Moving backward may fail if the cursor's plan was not created with the `CURSOR_OPT_SCROLL` option.

# SPI\_scroll\_cursor\_fetch

## Name

`SPI_scroll_cursor_fetch` — fetch some rows from a cursor

## Synopsis

```
void SPI_scroll_cursor_fetch(Portal portal, FetchDirection direction, long count)
```

## Description

`SPI_scroll_cursor_fetch` fetches some rows from a cursor. This is equivalent to the SQL command `FETCH`.

## Arguments

`Portal portal`

portal containing the cursor

`FetchDirection direction`

one of `FETCH_FORWARD`, `FETCH_BACKWARD`, `FETCH_ABSOLUTE` or `FETCH_RELATIVE`

`long count`

number of rows to fetch for `FETCH_FORWARD` or `FETCH_BACKWARD`; absolute row number to fetch for `FETCH_ABSOLUTE`; or relative row number to fetch for `FETCH_RELATIVE`

## Return Value

`SPI_processed` and `SPI_tuptable` are set as in `SPI_execute` if successful.

## Notes

See the SQL *FETCH* command for details of the interpretation of the `direction` and `count` parameters.

Direction values other than `FETCH_FORWARD` may fail if the cursor's plan was not created with the `CURSOR_OPT_SCROLL` option.

# SPI\_scroll\_cursor\_move

## Name

`SPI_scroll_cursor_move` — move a cursor

## Synopsis

```
void SPI_scroll_cursor_move(Portal portal, FetchDirection direction, long count)
```

## Description

`SPI_scroll_cursor_move` skips over some number of rows in a cursor. This is equivalent to the SQL command `MOVE`.

## Arguments

`Portal portal`

portal containing the cursor

`FetchDirection direction`

one of `FETCH_FORWARD`, `FETCH_BACKWARD`, `FETCH_ABSOLUTE` or `FETCH_RELATIVE`

`long count`

number of rows to move for `FETCH_FORWARD` or `FETCH_BACKWARD`; absolute row number to move to for `FETCH_ABSOLUTE`; or relative row number to move to for `FETCH_RELATIVE`

## Return Value

`SPI_processed` is set as in `SPI_execute` if successful. `SPI_tuptable` is set to `NULL`, since no rows are returned by this function.

## Notes

See the SQL *FETCH* command for details of the interpretation of the `direction` and `count` parameters.

Direction values other than `FETCH_FORWARD` may fail if the cursor's plan was not created with the `CURSOR_OPT_SCROLL` option.

# SPI\_cursor\_close

## Name

`SPI_cursor_close` — close a cursor

## Synopsis

```
void SPI_cursor_close(Portal portal)
```

## Description

`SPI_cursor_close` closes a previously created cursor and releases its portal storage.

All open cursors are closed automatically at the end of a transaction. `SPI_cursor_close` need only be invoked if it is desirable to release resources sooner.

## Arguments

`Portal portal`

portal containing the cursor

# SPI\_saveplan

## Name

SPI\_saveplan — save a plan

## Synopsis

```
SPIPlanPtr SPI_saveplan(SPIPlanPtr plan)
```

## Description

SPI\_saveplan saves a passed plan (prepared by SPI\_prepare) in memory that will not be freed by SPI\_finish nor by the transaction manager, and returns a pointer to the saved plan. This gives you the ability to reuse prepared plans in the subsequent invocations of your procedure in the current session.

## Arguments

SPIPlanPtr plan  
the plan to be saved

## Return Value

Pointer to the saved plan; NULL if unsuccessful. On error, SPI\_result is set thus:

SPI\_ERROR\_ARGUMENT  
if plan is NULL or invalid  
SPI\_ERROR\_UNCONNECTED  
if called from an unconnected procedure

## Notes

The passed-in plan is not freed, so you might wish to do SPI\_freeplan on it to avoid leaking memory until SPI\_finish.

If one of the objects (a table, function, etc.) referenced by the prepared plan is dropped or redefined, then future executions of SPI\_execute\_plan may fail or return different results than the plan initially indicates.

## 42.2. Interface Support Functions

The functions described here provide an interface for extracting information from result sets returned by `SPI_execute` and other SPI functions.

All functions described in this section can be used by both connected and unconnected procedures.

### SPI\_fname

#### Name

`SPI_fname` — determine the column name for the specified column number

#### Synopsis

```
char * SPI_fname(TupleDesc rowdesc, int colnumber)
```

#### Description

`SPI_fname` returns a copy of the column name of the specified column. (You can use `pfree` to release the copy of the name when you don't need it anymore.)

#### Arguments

`TupleDesc rowdesc`

input row description

`int colnumber`

column number (count starts at 1)

#### Return Value

The column name; NULL if `colnumber` is out of range. `SPI_result` set to `SPI_ERROR_NOATTRIBUTE` on error.

# SPI\_fnumber

## Name

`SPI_fnumber` — determine the column number for the specified column name

## Synopsis

```
int SPI_fnumber(TupleDesc rowdesc, const char * colname)
```

## Description

`SPI_fnumber` returns the column number for the column with the specified name.

If `colname` refers to a system column (e.g., `oid`) then the appropriate negative column number will be returned. The caller should be careful to test the return value for exact equality to `SPI_ERROR_NOATTRIBUTE` to detect an error; testing the result for less than or equal to 0 is not correct unless system columns should be rejected.

## Arguments

`TupleDesc rowdesc`

input row description

`const char * colname`

column name

## Return Value

Column number (count starts at 1), or `SPI_ERROR_NOATTRIBUTE` if the named column was not found.

# SPI\_getvalue

## Name

`SPI_getvalue` — return the string value of the specified column

## Synopsis

```
char * SPI_getvalue(HeapTuple row, TupleDesc rowdesc, int colnumber)
```

## Description

`SPI_getvalue` returns the string representation of the value of the specified column.

The result is returned in memory allocated using `palloc`. (You can use `pfree` to release the memory when you don't need it anymore.)

## Arguments

`HeapTuple row`

input row to be examined

`TupleDesc rowdesc`

input row description

`int colnumber`

column number (count starts at 1)

## Return Value

Column value, or `NULL` if the column is null, `colnumber` is out of range (`SPI_result` is set to `SPI_ERROR_NOATTRIBUTE`), or no output function is available (`SPI_result` is set to `SPI_ERROR_NOOUTFUNC`).

# SPI\_getbinval

## Name

`SPI_getbinval` — return the binary value of the specified column

## Synopsis

```
Datum SPI_getbinval(HeapTuple row, TupleDesc rowdesc, int colnumber, bool * isnull)
```

## Description

`SPI_getbinval` returns the value of the specified column in the internal form (as type `Datum`).

This function does not allocate new space for the datum. In the case of a pass-by-reference data type, the return value will be a pointer into the passed row.

## Arguments

`HeapTuple row`

input row to be examined

`TupleDesc rowdesc`

input row description

`int colnumber`

column number (count starts at 1)

`bool * isnull`

flag for a null value in the column

## Return Value

The binary value of the column is returned. The variable pointed to by `isnull` is set to true if the column is null, else to false.

`SPI_result` is set to `SPI_ERROR_NOATTRIBUTE` on error.

# SPI\_gettype

## Name

`SPI_gettype` — return the data type name of the specified column

## Synopsis

```
char * SPI_gettype(TupleDesc rowdesc, int colnumber)
```

## Description

`SPI_gettype` returns a copy of the data type name of the specified column. (You can use `pfree` to release the copy of the name when you don't need it anymore.)

## Arguments

`TupleDesc rowdesc`

input row description

`int colnumber`

column number (count starts at 1)

## Return Value

The data type name of the specified column, or `NULL` on error. `SPI_result` is set to `SPI_ERROR_NOATTRIBUTE` on error.

# SPI\_gettypeid

## Name

`SPI_gettypeid` — return the data type OID of the specified column

## Synopsis

```
Oid SPI_gettypeid(TupleDesc rowdesc, int colnumber)
```

## Description

`SPI_gettypeid` returns the OID of the data type of the specified column.

## Arguments

```
TupleDesc rowdesc
```

input row description

```
int colnumber
```

column number (count starts at 1)

## Return Value

The OID of the data type of the specified column or `InvalidOid` on error. On error, `SPI_result` is set to `SPI_ERROR_NOATTRIBUTE`.

# SPI\_getrelname

## Name

`SPI_getrelname` — return the name of the specified relation

## Synopsis

```
char * SPI_getrelname(Relation rel)
```

## Description

`SPI_getrelname` returns a copy of the name of the specified relation. (You can use `pfree` to release the copy of the name when you don't need it anymore.)

## Arguments

```
Relation rel  
    input relation
```

## Return Value

The name of the specified relation.

# SPI\_getnspname

## Name

`SPI_getnspname` — return the namespace of the specified relation

## Synopsis

```
char * SPI_getnspname(Relation rel)
```

## Description

`SPI_getnspname` returns a copy of the name of the namespace that the specified `Relation` belongs to. This is equivalent to the relation's schema. You should `pfree` the return value of this function when you are finished with it.

## Arguments

`Relation rel`  
input relation

## Return Value

The name of the specified relation's namespace.

## 42.3. Memory Management

PostgreSQL allocates memory within *memory contexts*, which provide a convenient method of managing allocations made in many different places that need to live for differing amounts of time. Destroying a context releases all the memory that was allocated in it. Thus, it is not necessary to keep track of individual objects to avoid memory leaks; instead only a relatively small number of contexts have to be managed. `palloc` and related functions allocate memory from the “current” context.

`SPI_connect` creates a new memory context and makes it current. `SPI_finish` restores the previous current memory context and destroys the context created by `SPI_connect`. These actions ensure that transient memory allocations made inside your procedure are reclaimed at procedure exit, avoiding memory leakage.

However, if your procedure needs to return an object in allocated memory (such as a value of a pass-by-reference data type), you cannot allocate that memory using `palloc`, at least not while you are connected to SPI. If you try, the object will be deallocated by `SPI_finish`, and your procedure will not work reliably. To solve this problem, use `SPI_palloc` to allocate memory for your return object. `SPI_palloc` allocates memory in the “upper executor context”, that is, the memory context that was current when `SPI_connect` was called, which is precisely the right context for a value returned from your procedure.

If `SPI_palloc` is called while the procedure is not connected to SPI, then it acts the same as a normal `palloc`. Before a procedure connects to the SPI manager, the current memory context is the upper executor context, so all allocations made by the procedure via `palloc` or by SPI utility functions are made in this context.

When `SPI_connect` is called, the private context of the procedure, which is created by `SPI_connect`, is made the current context. All allocations made by `palloc`, `repalloc`, or SPI utility functions (except for `SPI_copytuple`, `SPI_returntuple`, `SPI_modifytuple`, and `SPI_palloc`) are made in this context. When a procedure disconnects from the SPI manager (via `SPI_finish`) the current context is restored to the upper executor context, and all allocations made in the procedure memory context are freed and cannot be used any more.

All functions described in this section can be used by both connected and unconnected procedures. In an unconnected procedure, they act the same as the underlying ordinary server functions (`palloc`, etc.).

### SPI\_palloc

#### Name

`SPI_palloc` — allocate memory in the upper executor context

#### Synopsis

```
void * SPI_palloc(Size size)
```

## Description

`SPI_palloc` allocates memory in the upper executor context.

## Arguments

`Size size`

size in bytes of storage to allocate

## Return Value

pointer to new storage space of the specified size

# SPI\_realloc

## Name

`SPI_realloc` — reallocate memory in the upper executor context

## Synopsis

```
void * SPI_realloc(void * pointer, Size size)
```

## Description

`SPI_realloc` changes the size of a memory segment previously allocated using `SPI_palloc`.

This function is no longer different from plain `realloc`. It's kept just for backward compatibility of existing code.

## Arguments

```
void * pointer
```

pointer to existing storage to change

```
Size size
```

size in bytes of storage to allocate

## Return Value

pointer to new storage space of specified size with the contents copied from the existing area

# SPI\_pfree

## Name

SPI\_pfree — free memory in the upper executor context

## Synopsis

```
void SPI_pfree(void * pointer)
```

## Description

SPI\_pfree frees memory previously allocated using SPI\_palloc or SPI\_realloc.

This function is no longer different from plain pfree. It's kept just for backward compatibility of existing code.

## Arguments

```
void * pointer
```

pointer to existing storage to free

# SPI\_copytuple

## Name

`SPI_copytuple` — make a copy of a row in the upper executor context

## Synopsis

```
HeapTuple SPI_copytuple(HeapTuple row)
```

## Description

`SPI_copytuple` makes a copy of a row in the upper executor context. This is normally used to return a modified row from a trigger. In a function declared to return a composite type, use `SPI_returntuple` instead.

## Arguments

```
HeapTuple row
```

row to be copied

## Return Value

the copied row; `NULL` only if `tuple` is `NULL`

# SPI\_returntuple

## Name

`SPI_returntuple` — prepare to return a tuple as a Datum

## Synopsis

```
HeapTupleHeader SPI_returntuple(HeapTuple row, TupleDesc rowdesc)
```

## Description

`SPI_returntuple` makes a copy of a row in the upper executor context, returning it in the form of a row type `Datum`. The returned pointer need only be converted to `Datum` via `PointerGetDatum` before returning.

Note that this should be used for functions that are declared to return composite types. It is not used for triggers; use `SPI_copytuple` for returning a modified row in a trigger.

## Arguments

`HeapTuple row`

row to be copied

`TupleDesc rowdesc`

descriptor for row (pass the same descriptor each time for most effective caching)

## Return Value

`HeapTupleHeader` pointing to copied row; `NULL` only if `row` or `rowdesc` is `NULL`

# SPI\_modifytuple

## Name

`SPI_modifytuple` — create a row by replacing selected fields of a given row

## Synopsis

```
HeapTuple SPI_modifytuple(Relation rel, HeapTuple row, ncols, colnum, Datum * values, const char * Nulls)
```

## Description

`SPI_modifytuple` creates a new row by substituting new values for selected columns, copying the original row's columns at other positions. The input row is not modified.

## Arguments

`Relation rel`

Used only as the source of the row descriptor for the row. (Passing a relation rather than a row descriptor is a misfeature.)

`HeapTuple row`

row to be modified

`int ncols`

number of column numbers in the array `colnum`

`int * colnum`

array of the numbers of the columns that are to be changed (column numbers start at 1)

`Datum * values`

new values for the specified columns

`const char * Nulls`

which new values are null, if any (see `SPI_execute_plan` for the format)

## Return Value

new row with modifications, allocated in the upper executor context; `NULL` only if `row` is `NULL`

On error, `SPI_result` is set as follows:

`SPI_ERROR_ARGUMENT`

if `rel` is NULL, or if `row` is NULL, or if `ncols` is less than or equal to 0, or if `colnum` is NULL, or if `values` is NULL.

`SPI_ERROR_NOATTRIBUTE`

if `colnum` contains an invalid column number (less than or equal to 0 or greater than the number of column in `row`)

# SPI\_freetuple

## Name

`SPI_freetuple` — free a row allocated in the upper executor context

## Synopsis

```
void SPI_freetuple(HeapTuple row)
```

## Description

`SPI_freetuple` frees a row previously allocated in the upper executor context.

This function is no longer different from plain `heap_freetuple`. It's kept just for backward compatibility of existing code.

## Arguments

`HeapTuple row`

row to free

# SPI\_freetuptable

## Name

`SPI_freetuptable` — free a row set created by `SPI_execute` or a similar function

## Synopsis

```
void SPI_freetuptable(SPITupleTable * tuptable)
```

## Description

`SPI_freetuptable` frees a row set created by a prior SPI command execution function, such as `SPI_execute`. Therefore, this function is usually called with the global variable `SPI_tupletable` as argument.

This function is useful if a SPI procedure needs to execute multiple commands and does not want to keep the results of earlier commands around until it ends. Note that any unfreed row sets will be freed anyway at `SPI_finish`.

## Arguments

```
SPITupleTable * tuptable  
    pointer to row set to free
```

# SPI\_freeplan

## Name

SPI\_freeplan — free a previously saved plan

## Synopsis

```
int SPI_freeplan(SPIPlanPtr plan)
```

## Description

SPI\_freeplan releases a command execution plan previously returned by SPI\_prepare or saved by SPI\_saveplan.

## Arguments

SPIPlanPtr plan  
pointer to plan to free

## Return Value

SPI\_ERROR\_ARGUMENT if plan is NULL or invalid

## 42.4. Visibility of Data Changes

The following rules govern the visibility of data changes in functions that use SPI (or any other C function):

- During the execution of an SQL command, any data changes made by the command are invisible to the command itself. For example, in:

```
INSERT INTO a SELECT * FROM a;
the inserted rows are invisible to the SELECT part.
```

- Changes made by a command *C* are visible to all commands that are started after *C*, no matter whether they are started inside *C* (during the execution of *C*) or after *C* is done.
- Commands executed via SPI inside a function called by an SQL command (either an ordinary function or a trigger) follow one or the other of the above rules depending on the read/write flag passed to SPI. Commands executed in read-only mode follow the first rule: they cannot see changes of the calling command. Commands executed in read-write mode follow the second rule: they can see all changes made so far.
- All standard procedural languages set the SPI read-write mode depending on the volatility attribute of the function. Commands of `STABLE` and `IMMUTABLE` functions are done in read-only mode, while commands of `VOLATILE` functions are done in read-write mode. While authors of C functions are able to violate this convention, it's unlikely to be a good idea to do so.

The next section contains an example that illustrates the application of these rules.

## 42.5. Examples

This section contains a very simple example of SPI usage. The procedure `execq` takes an SQL command as its first argument and a row count as its second, executes the command using `SPI_exec` and returns the number of rows that were processed by the command. You can find more complex examples for SPI in the source tree in `src/test/regress/regress.c` and in `contrib/spi`.

```
#include "executor/spi.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

int execq(text *sql, int cnt);

int
execq(text *sql, int cnt)
{
    char *command;
    int ret;
    int proc;
```

```

/* Convert given text object to a C string */
command = DatumGetCString(DirectFunctionCall1(textout,
                                              PointerGetDatum(sql)));

SPI_connect();

ret = SPI_exec(command, cnt);

proc = SPI_processed;
/*
 * If some rows were fetched, print them via elog(INFO).
 */
if (ret > 0 && SPI_tuptable != NULL)
{
    TupleDesc tupdesc = SPI_tuptable->tupdesc;
    SPITupleTable *tuptable = SPI_tuptable;
    char buf[8192];
    int i, j;

    for (j = 0; j < proc; j++)
    {
        HeapTuple tuple = tuptable->vals[j];

        for (i = 1, buf[0] = 0; i <= tupdesc->natts; i++)
            snprintf(buf + strlen(buf), sizeof(buf) - strlen(buf), " %s%s",
                     SPI_getvalue(tuple, tupdesc, i),
                     (i == tupdesc->natts) ? " " : " |");
        elog(INFO, "EXECQ: %s", buf);
    }
}

SPI_finish();
pfree(command);

return (proc);
}

```

(This function uses call convention version 0, to make the example easier to understand. In real applications you should use the new version 1 interface.)

This is how you declare the function after having compiled it into a shared library (details are in Section 34.9.6):

```

CREATE FUNCTION execq(text, integer) RETURNS integer
AS 'filename'
LANGUAGE C;

```

Here is a sample session:

```

=> SELECT execq('CREATE TABLE a (x integer)', 0);
execq
-----

```

```

      0
(1 row)

=> INSERT INTO a VALUES (execq('INSERT INTO a VALUES (0)', 0));
INSERT 0 1
=> SELECT execq('SELECT * FROM a', 0);
INFO:  EXECQ:  0      -- inserted by execq
INFO:  EXECQ:  1      -- returned by execq and inserted by upper INSERT

execq
-----
      2
(1 row)

=> SELECT execq('INSERT INTO a SELECT x + 2 FROM a', 1);
execq
-----
      1
(1 row)

=> SELECT execq('SELECT * FROM a', 10);
INFO:  EXECQ:  0
INFO:  EXECQ:  1
INFO:  EXECQ:  2      -- 0 + 2, only one row inserted - as specified

execq
-----
      3              -- 10 is the max value only, 3 is the real number of rows
(1 row)

=> DELETE FROM a;
DELETE 3
=> INSERT INTO a VALUES (execq('SELECT * FROM a', 0) + 1);
INSERT 0 1
=> SELECT * FROM a;
 x
---
 1              -- no rows in a (0) + 1
(1 row)

=> INSERT INTO a VALUES (execq('SELECT * FROM a', 0) + 1);
INFO:  EXECQ:  1
INSERT 0 1
=> SELECT * FROM a;
 x
---
 1
 2              -- there was one row in a + 1
(2 rows)

-- This demonstrates the data changes visibility rule:

=> INSERT INTO a SELECT execq('SELECT * FROM a', 0) * x FROM a;

```

```

INFO: EXECQ: 1
INFO: EXECQ: 2
INFO: EXECQ: 1
INFO: EXECQ: 2
INFO: EXECQ: 2
INSERT 0 2
=> SELECT * FROM a;
  x
---
 1
 2
 2          -- 2 rows * 1 (x in first row)
 6          -- 3 rows (2 + 1 just inserted) * 2 (x in second row)
(4 rows)    ^^^^^^

              rows visible to execq() in different invocations

```

## VI. Reference

The entries in this Reference are meant to provide in reasonable length an authoritative, complete, and formal summary about their respective subjects. More information about the use of PostgreSQL, in narrative, tutorial, or example form, can be found in other parts of this book. See the cross-references listed on each reference page.

The reference entries are also available as traditional “man” pages.

# I. SQL Commands

This part contains reference information for the SQL commands supported by PostgreSQL. By “SQL” the language in general is meant; information about the standards conformance and compatibility of each command can be found on the respective reference page.

# ABORT

## Name

ABORT — abort the current transaction

## Synopsis

```
ABORT [ WORK | TRANSACTION ]
```

## Description

ABORT rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command *ROLLBACK*, and is present only for historical reasons.

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

## Notes

Use *COMMIT* to successfully terminate a transaction.

Issuing ABORT when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To abort all changes:

```
ABORT;
```

## Compatibility

This command is a PostgreSQL extension present for historical reasons. `ROLLBACK` is the equivalent standard SQL command.

## See Also

*BEGIN, COMMIT, ROLLBACK*

# ALTER AGGREGATE

## Name

ALTER AGGREGATE — change the definition of an aggregate function

## Synopsis

```
ALTER AGGREGATE name ( type [ , ... ] ) RENAME TO new_name
ALTER AGGREGATE name ( type [ , ... ] ) OWNER TO new_owner
ALTER AGGREGATE name ( type [ , ... ] ) SET SCHEMA new_schema
```

## Description

ALTER AGGREGATE changes the definition of an aggregate function.

You must own the aggregate function to use ALTER AGGREGATE. To change the schema of an aggregate function, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the aggregate function's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

## Parameters

*name*

The name (optionally schema-qualified) of an existing aggregate function.

*type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write \* in place of the list of input data types.

*new\_name*

The new name of the aggregate function.

*new\_owner*

The new owner of the aggregate function.

*new\_schema*

The new schema for the aggregate function.

## Examples

To rename the aggregate function `myavg` for type `integer` to `my_average`:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function `myavg` for type `integer` to `joe`:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the aggregate function `myavg` for type `integer` into schema `myschema`:

```
ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;
```

## Compatibility

There is no `ALTER AGGREGATE` statement in the SQL standard.

## See Also

*CREATE AGGREGATE, DROP AGGREGATE*

# ALTER CONVERSION

## Name

ALTER CONVERSION — change the definition of a conversion

## Synopsis

```
ALTER CONVERSION name RENAME TO newname  
ALTER CONVERSION name OWNER TO newowner
```

## Description

ALTER CONVERSION changes the definition of a conversion.

You must own the conversion to use ALTER CONVERSION. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the conversion's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

## Parameters

*name*

The name (optionally schema-qualified) of an existing conversion.

*newname*

The new name of the conversion.

*newowner*

The new owner of the conversion.

## Examples

To rename the conversion `iso_8859_1_to_utf8` to `latin1_to_unicode`:

```
ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO latin1_to_unicode;
```

To change the owner of the conversion `iso_8859_1_to_utf8` to `joe`:

```
ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;
```

## **Compatibility**

There is no `ALTER CONVERSION` statement in the SQL standard.

## **See Also**

*CREATE CONVERSION*, *DROP CONVERSION*

# ALTER DATABASE

## Name

ALTER DATABASE — change a database

## Synopsis

```
ALTER DATABASE name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
CONNECTION LIMIT conlimit
```

```
ALTER DATABASE name RENAME TO newname
```

```
ALTER DATABASE name OWNER TO new_owner
```

```
ALTER DATABASE name SET configuration_parameter { TO | = } { value | DEFAULT }
```

```
ALTER DATABASE name SET configuration_parameter FROM CURRENT
```

```
ALTER DATABASE name RESET configuration_parameter
```

```
ALTER DATABASE name RESET ALL
```

## Description

ALTER DATABASE changes the attributes of a database.

The first form changes certain per-database settings. (See below for details.) Only the database owner or a superuser can change these settings.

The second form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the `CREATEDB` privilege. The current database cannot be renamed. (Connect to a different database if you need to do that.)

The third form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the `CREATEDB` privilege. (Note that superusers have all these privileges automatically.)

The remaining forms change the session default for a run-time configuration variable for a PostgreSQL database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in `postgresql.conf` or has been received from the `postgres` command line. Only the database owner or a superuser can change the session defaults for a database. Certain variables cannot be set this way, or can only be set by a superuser.

## Parameters

*name*

The name of the database whose attributes are to be altered.

*conlimit*

How many concurrent connections can be made to this database. -1 means no limit.

*newname*

The new name of the database.

*new\_owner*

The new owner of the database.

*configuration\_parameter*

*value*

Set this database's session default for the specified configuration parameter to the given value. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use `RESET ALL` to clear all database-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the database-specific value.

See *SET* and Chapter 18 for more information about allowed parameter names and values.

## Notes

It is also possible to tie a session default to a specific role rather than to a database; see *ALTER ROLE*. Role-specific settings override database-specific ones if there is a conflict.

## Examples

To disable index scans by default in the database `test`:

```
ALTER DATABASE test SET enable_indexscan TO off;
```

## Compatibility

The `ALTER DATABASE` statement is a PostgreSQL extension.

## See Also

*CREATE DATABASE*, *DROP DATABASE*, *SET*

# ALTER DOMAIN

## Name

ALTER DOMAIN — change the definition of a domain

## Synopsis

```
ALTER DOMAIN name
    { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name
    { SET | DROP } NOT NULL
ALTER DOMAIN name
    ADD domain_constraint
ALTER DOMAIN name
    DROP CONSTRAINT constraint_name [ RESTRICT | CASCADE ]
ALTER DOMAIN name
    OWNER TO new_owner
ALTER DOMAIN name
    SET SCHEMA new_schema
```

## Description

ALTER DOMAIN changes the definition of an existing domain. There are several sub-forms:

### SET/DROP DEFAULT

These forms set or remove the default value for a domain. Note that defaults only apply to subsequent INSERT commands; they do not affect rows already in a table using the domain.

### SET/DROP NOT NULL

These forms change whether a domain is marked to allow NULL values or to reject NULL values. You can only SET NOT NULL when the columns using the domain contain no null values.

### ADD *domain\_constraint*

This form adds a new constraint to a domain using the same syntax as *CREATE DOMAIN*. This will only succeed if all columns using the domain satisfy the new constraint.

### DROP CONSTRAINT

This form drops constraints on a domain.

### OWNER

This form changes the owner of the domain to the specified user.

**SET SCHEMA**

This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use `ALTER DOMAIN`. To change the schema of a domain, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the domain's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

**Parameters**

*name*

The name (possibly schema-qualified) of an existing domain to alter.

*domain\_constraint*

New domain constraint for the domain.

*constraint\_name*

Name of an existing constraint to drop.

`CASCADE`

Automatically drop objects that depend on the constraint.

`RESTRICT`

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

*new\_owner*

The user name of the new owner of the domain.

*new\_schema*

The new schema for the domain.

**Notes**

Currently, `ALTER DOMAIN ADD CONSTRAINT` and `ALTER DOMAIN SET NOT NULL` will fail if the named domain or any derived domain is used within a composite-type column of any table in the database. They should eventually be improved to be able to verify the new constraint for such nested columns.

## Examples

To add a NOT NULL constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a NOT NULL constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

## Compatibility

ALTER DOMAIN conforms to the SQL standard, except for the OWNER and SET SCHEMA variants, which are PostgreSQL extensions.

## See Also

*CREATE DOMAIN, DROP DOMAIN*

# ALTER FUNCTION

## Name

ALTER FUNCTION — change the definition of a function

## Synopsis

```
ALTER FUNCTION name ( [ [ argmode ] [ argname ] argtype [, ...] ] )  
    action [ ... ] [ RESTRICT ]  
ALTER FUNCTION name ( [ [ argmode ] [ argname ] argtype [, ...] ] )  
    RENAME TO new_name  
ALTER FUNCTION name ( [ [ argmode ] [ argname ] argtype [, ...] ] )  
    OWNER TO new_owner  
ALTER FUNCTION name ( [ [ argmode ] [ argname ] argtype [, ...] ] )  
    SET SCHEMA new_schema
```

where *action* is one of:

```
    CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT  
    IMMUTABLE | STABLE | VOLATILE  
    [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER  
    COST execution_cost  
    ROWS result_rows  
    SET configuration_parameter { TO | = } { value | DEFAULT }  
    SET configuration_parameter FROM CURRENT  
    RESET configuration_parameter  
    RESET ALL
```

## Description

ALTER FUNCTION changes the definition of a function.

You must own the function to use ALTER FUNCTION. To change a function's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the function's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

## Parameters

*name*

The name (optionally schema-qualified) of an existing function.

*argmode*

The mode of an argument: either `IN`, `OUT`, or `INOUT`. If omitted, the default is `IN`. Note that `ALTER FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN` and `INOUT` arguments.

*argname*

The name of an argument. Note that `ALTER FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any.

*new\_name*

The new name of the function.

*new\_owner*

The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently execute as the new owner.

*new\_schema*

The new schema for the function.

`CALLED ON NULL INPUT`

`RETURNS NULL ON NULL INPUT`

`STRICT`

`CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. See *CREATE FUNCTION* for more information.

`IMMUTABLE`

`STABLE`

`VOLATILE`

Change the volatility of the function to the specified setting. See *CREATE FUNCTION* for details.

`[ EXTERNAL ] SECURITY INVOKER`

`[ EXTERNAL ] SECURITY DEFINER`

Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See *CREATE FUNCTION* for more information about this capability.

`COST execution_cost`

Change the estimated execution cost of the function. See *CREATE FUNCTION* for more information.

`ROWS result_rows`

Change the estimated number of rows returned by a set-returning function. See *CREATE FUNCTION* for more information.

*configuration\_parameter*  
*value*

Add or change the assignment to be made to a configuration parameter when the function is called. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the function-local setting is removed, so that the function executes with the value present in its environment. Use `RESET ALL` to clear all function-local settings. `SET FROM CURRENT` saves the session's current value of the parameter as the value to be applied when the function is entered.

See *SET* and Chapter 18 for more information about allowed parameter names and values.

`RESTRICT`

Ignored for conformance with the SQL standard.

## Examples

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the schema of the function `sqrt` for type `integer` to `maths`:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA maths;
```

To adjust the search path that is automatically set for a function:

```
ALTER FUNCTION check_password(text) SET search_path = admin, pg_temp;
```

To disable automatic setting of `search_path` for a function:

```
ALTER FUNCTION check_password(text) RESET search_path;
```

The function will now execute with whatever search path is used by its caller.

## Compatibility

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, attach configuration parameter values to a function, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in PostgreSQL.

*CREATE FUNCTION, DROP FUNCTION*

# ALTER GROUP

## Name

ALTER GROUP — change role name or membership

## Synopsis

```
ALTER GROUP groupname ADD USER username [, ... ]  
ALTER GROUP groupname DROP USER username [, ... ]
```

```
ALTER GROUP groupname RENAME TO newname
```

## Description

ALTER GROUP changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because groups (and users too) have been superseded by the more general concept of roles.

The first two variants add users to a group or remove them from a group. (Any role can play the part of either a “user” or a “group” for this purpose.) These variants are effectively equivalent to granting or revoking membership in the role named as the “group”; so the preferred way to do this is to use *GRANT* or *REVOKE*.

The third variant changes the name of the group. This is exactly equivalent to renaming the role with *ALTER ROLE*.

## Parameters

*groupname*

The name of the group (role) to modify.

*username*

Users (roles) that are to be added to or removed from the group. The users must already exist; ALTER GROUP does not create or drop users.

*newname*

The new name of the group.

## Examples

Add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

Remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

## Compatibility

There is no `ALTER GROUP` statement in the SQL standard.

## See Also

*GRANT*, *REVOKE*, *ALTER ROLE*

# ALTER INDEX

## Name

ALTER INDEX — change the definition of an index

## Synopsis

```
ALTER INDEX name RENAME TO new_name
ALTER INDEX name SET TABLESPACE tablespace_name
ALTER INDEX name SET ( storage_parameter = value [, ... ] )
ALTER INDEX name RESET ( storage_parameter [, ... ] )
```

## Description

ALTER INDEX changes the definition of an existing index. There are several subforms:

RENAME

The RENAME form changes the name of the index. There is no effect on the stored data.

SET TABLESPACE

This form changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. See also *CREATE TABLESPACE*.

SET ( *storage\_parameter* = *value* [, ... ] )

This form changes one or more index-method-specific storage parameters for the index. See *CREATE INDEX* for details on the available parameters. Note that the index contents will not be modified immediately by this command; depending on the parameter you might need to rebuild the index with *REINDEX* to get the desired effects.

RESET ( *storage\_parameter* [, ... ] )

This form resets one or more index-method-specific storage parameters to their defaults. As with SET, a REINDEX might be needed to update the index entirely.

## Parameters

*name*

The name (possibly schema-qualified) of an existing index to alter.

*new\_name*

The new name for the index.

*tablespace\_name*

The tablespace to which the index will be moved.

*storage\_parameter*

The name of an index-method-specific storage parameter.

*value*

The new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

## Notes

These operations are also possible using *ALTER TABLE*. *ALTER INDEX* is in fact just an alias for the forms of *ALTER TABLE* that apply to indexes.

There was formerly an *ALTER INDEX OWNER* variant, but this is now ignored (with a warning). An index cannot have an owner different from its table's owner. Changing the table's owner automatically changes the index as well.

Changing any part of a system catalog index is not permitted.

## Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);
REINDEX INDEX distributors;
```

## Compatibility

*ALTER INDEX* is a PostgreSQL extension.

## **See Also**

*CREATE INDEX, REINDEX*

# ALTER LANGUAGE

## Name

ALTER LANGUAGE — change the definition of a procedural language

## Synopsis

```
ALTER [ PROCEDURAL ] LANGUAGE name RENAME TO newname  
ALTER [ PROCEDURAL ] LANGUAGE name OWNER TO new_owner
```

## Description

ALTER LANGUAGE changes the definition of a procedural language. The only functionality is to rename the language or assign a new owner. You must be superuser or owner of the language to use ALTER LANGUAGE.

## Parameters

*name*

Name of a language

*newname*

The new name of the language

*new\_owner*

The new owner of the language

## Compatibility

There is no ALTER LANGUAGE statement in the SQL standard.

## See Also

CREATE LANGUAGE, DROP LANGUAGE

# ALTER OPERATOR

## Name

ALTER OPERATOR — change the definition of an operator

## Synopsis

```
ALTER OPERATOR name ( { lefttype | NONE } , { righttype | NONE } ) OWNER TO newowner
```

## Description

ALTER OPERATOR changes the definition of an operator. The only currently available functionality is to change the owner of the operator.

You must own the operator to use ALTER OPERATOR. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

## Parameters

*name*

The name (optionally schema-qualified) of an existing operator.

*lefttype*

The data type of the operator's left operand; write NONE if the operator has no left operand.

*righttype*

The data type of the operator's right operand; write NONE if the operator has no right operand.

*newowner*

The new owner of the operator.

## Examples

Change the owner of a custom operator a @@ b for type text:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

## **Compatibility**

There is no `ALTER OPERATOR` statement in the SQL standard.

## **See Also**

*CREATE OPERATOR, DROP OPERATOR*

# ALTER OPERATOR CLASS

## Name

ALTER OPERATOR CLASS — change the definition of an operator class

## Synopsis

```
ALTER OPERATOR CLASS name USING index_method RENAME TO newname
ALTER OPERATOR CLASS name USING index_method OWNER TO newowner
```

## Description

ALTER OPERATOR CLASS changes the definition of an operator class.

You must own the operator class to use ALTER OPERATOR CLASS. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator class's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

## Parameters

*name*

The name (optionally schema-qualified) of an existing operator class.

*index\_method*

The name of the index method this operator class is for.

*newname*

The new name of the operator class.

*newowner*

The new owner of the operator class.

## Compatibility

There is no ALTER OPERATOR CLASS statement in the SQL standard.

## See Also

CREATE OPERATOR CLASS, DROP OPERATOR CLASS, ALTER OPERATOR FAMILY

# ALTER OPERATOR FAMILY

## Name

ALTER OPERATOR FAMILY — change the definition of an operator family

## Synopsis

```
ALTER OPERATOR FAMILY name USING index_method ADD
{ OPERATOR strategy_number operator_name ( op_type, op_type ) [ RECHECK ]
  | FUNCTION support_number [ ( op_type [ , op_type ] ) ] funcname ( argument_type [, ...] )
} [, ... ]
ALTER OPERATOR FAMILY name USING index_method DROP
{ OPERATOR strategy_number ( op_type [ , op_type ] )
  | FUNCTION support_number ( op_type [ , op_type ] )
} [, ... ]
ALTER OPERATOR FAMILY name USING index_method RENAME TO newname
ALTER OPERATOR FAMILY name USING index_method OWNER TO newowner
```

## Description

ALTER OPERATOR FAMILY changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family's name or owner.

When operators and support functions are added to a family with ALTER OPERATOR FAMILY, they are not part of any specific operator class within the family, but are just “loose” within the family. This indicates that these operators and functions are compatible with the family's semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see *CREATE OPERATOR CLASS*.) PostgreSQL will allow loose members of a family to be dropped from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use ALTER OPERATOR FAMILY. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

ALTER OPERATOR FAMILY does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

Refer to Section 34.14 for further information.

## Parameters

*name*

The name (optionally schema-qualified) of an existing operator family.

*index\_method*

The name of the index method this operator family is for.

*strategy\_number*

The index method's strategy number for an operator associated with the operator family.

*operator\_name*

The name (optionally schema-qualified) of an operator associated with the operator family.

*op\_type*

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. Unlike the comparable syntax in `CREATE OPERATOR CLASS`, the operand data types must always be specified.

In an `ADD FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree and hash indexes it is not necessary to specify *op\_type* since the function's input data type(s) are always the correct ones to use. For GIN and GiST indexes it is necessary to specify the input data type the function is to be used with.

In a `DROP FUNCTION` clause, the operand data type(s) the function is intended to support must be specified.

*RECHECK*

If present, the index is “lossy” for this operator, and so the rows retrieved using the index must be rechecked to verify that they actually satisfy the qualification clause involving this operator.

*support\_number*

The index method's support procedure number for a function associated with the operator family.

*funcname*

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator family.

*argument\_types*

The parameter data type(s) of the function.

*newname*

The new name of the operator family.

*newowner*

The new owner of the operator family.

The `OPERATOR` and `FUNCTION` clauses can appear in any order.

## Notes

Notice that the `DROP` syntax only specifies the “slot” in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for `DROP FUNCTION` the type(s) to specify are the input data type(s) the function is intended to support; for GIN and GiST indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

## Examples

The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types `int4` and `int2`.

```
ALTER OPERATOR FAMILY integer_ops USING btree ADD
```

```
-- int4 vs int2
OPERATOR 1 < (int4, int2) ,
OPERATOR 2 <= (int4, int2) ,
OPERATOR 3 = (int4, int2) ,
OPERATOR 4 >= (int4, int2) ,
OPERATOR 5 > (int4, int2) ,
FUNCTION 1 btint42cmp(int4, int2) ,

-- int2 vs int4
OPERATOR 1 < (int2, int4) ,
OPERATOR 2 <= (int2, int4) ,
OPERATOR 3 = (int2, int4) ,
OPERATOR 4 >= (int2, int4) ,
OPERATOR 5 > (int2, int4) ,
FUNCTION 1 btint24cmp(int2, int4) ;
```

To remove these entries again:

```
ALTER OPERATOR FAMILY integer_ops USING btree DROP
```

```
-- int4 vs int2
OPERATOR 1 (int4, int2) ,
OPERATOR 2 (int4, int2) ,
OPERATOR 3 (int4, int2) ,
OPERATOR 4 (int4, int2) ,
OPERATOR 5 (int4, int2) ,
FUNCTION 1 (int4, int2) ,

-- int2 vs int4
OPERATOR 1 (int2, int4) ,
OPERATOR 2 (int2, int4) ,
```

```
OPERATOR 3 (int2, int4) ,  
OPERATOR 4 (int2, int4) ,  
OPERATOR 5 (int2, int4) ,  
FUNCTION 1 (int2, int4) ;
```

## Compatibility

There is no `ALTER OPERATOR FAMILY` statement in the SQL standard.

## See Also

*CREATE OPERATOR FAMILY, DROP OPERATOR FAMILY, CREATE OPERATOR CLASS, ALTER OPERATOR CLASS, DROP OPERATOR CLASS*

# ALTER ROLE

## Name

ALTER ROLE — change a database role

## Synopsis

```
ALTER ROLE name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
```

```
ALTER ROLE name RENAME TO newname
```

```
ALTER ROLE name SET configuration_parameter { TO | = } { value | DEFAULT }
ALTER ROLE name SET configuration_parameter FROM CURRENT
ALTER ROLE name RESET configuration_parameter
ALTER ROLE name RESET ALL
```

## Description

ALTER ROLE changes the attributes of a PostgreSQL role.

The first variant of this command listed in the synopsis can change many of the role attributes that can be specified in *CREATE ROLE*. (All the possible attributes are covered, except that there are no options for adding or removing memberships; use *GRANT* and *REVOKE* for that.) Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having *CREATEROLE* privilege can change any of these settings, but only for non-superuser roles. Ordinary roles can only change their own password.

The second variant changes the name of the role. Database superusers can rename any role. Roles having *CREATEROLE* privilege can rename non-superuser roles. The current session user cannot be renamed. (Connect as a different user if you need to do that.) Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

The remaining variants change a role's session default for a specified configuration variable. Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in `postgresql.conf` or has been received from the `postgres` command line. (For a role without *LOGIN* privilege, session defaults have no effect.) Ordinary roles can change

their own session defaults. Superusers can change anyone's session defaults. Roles having `CREATEROLE` privilege can change defaults for non-superuser roles. Certain variables cannot be set this way, or can only be set if a superuser issues the command.

## Parameters

*name*

The name of the role whose attributes are to be altered.

`SUPERUSER`  
`NOSUPERUSER`  
`CREATEDB`  
`NOCREATEDB`  
`CREATEROLE`  
`NOCREATEROLE`  
`CREATEUSER`  
`NOCREATEUSER`  
`INHERIT`  
`NOINHERIT`  
`LOGIN`  
`NOLOGIN`  
`CONNECTION LIMIT` *conlimit*  
`PASSWORD` *password*  
`ENCRYPTED`  
`UNENCRYPTED`  
`VALID UNTIL` '*timestamp*'

These clauses alter attributes originally set by `CREATE ROLE`. For more information, see the `CREATE ROLE` reference page.

*newname*

The new name of the role.

*configuration\_parameter*

*value*

Set this role's session default for the specified configuration parameter to the given value. If *value* is `DEFAULT` or, equivalently, `RESET` is used, the role-specific variable setting is removed, so the role will inherit the system-wide default setting in new sessions. Use `RESET ALL` to clear all role-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the role-specific value.

See `SET` and Chapter 18 for more information about allowed parameter names and values.

## Notes

Use `CREATE ROLE` to add new roles, and `DROP ROLE` to remove a role.

`ALTER ROLE` cannot change a role's memberships. Use `GRANT` and `REVOKE` to do that.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in cleartext, and it might also be logged in the client's command history or the server log. *psql* contains a command `\password` that can be used to safely change a role's password.

It is also possible to tie a session default to a specific database rather than to a role; see *ALTER DATABASE*. Role-specific settings override database-specific ones if there is a conflict.

## Examples

Change a role's password:

```
ALTER ROLE davide WITH PASSWORD 'hu8jmn3';
```

Change a password expiration date, specifying that the password should expire at midday on 4th May 2015 using the time zone which is one hour ahead of UTC:

```
ALTER ROLE chris VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE fred VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE miriam CREATEROLE CREATEDB;
```

Give a role a non-default setting of the `maintenance_work_mem` parameter:

```
ALTER ROLE worker_bee SET maintenance_work_mem = 100000;
```

## Compatibility

The `ALTER ROLE` statement is a PostgreSQL extension.

## See Also

*CREATE ROLE*, *DROP ROLE*, *SET*

# ALTER SCHEMA

## Name

ALTER SCHEMA — change the definition of a schema

## Synopsis

```
ALTER SCHEMA name RENAME TO newname
ALTER SCHEMA name OWNER TO newowner
```

## Description

ALTER SCHEMA changes the definition of a schema.

You must own the schema to use ALTER SCHEMA. To rename a schema you must also have the CREATE privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the CREATE privilege for the database. (Note that superusers have all these privileges automatically.)

## Parameters

*name*

The name of an existing schema.

*newname*

The new name of the schema. The new name cannot begin with `pg_`, as such names are reserved for system schemas.

*newowner*

The new owner of the schema.

## Compatibility

There is no ALTER SCHEMA statement in the SQL standard.

## See Also

CREATE SCHEMA, DROP SCHEMA

# ALTER SEQUENCE

## Name

ALTER SEQUENCE — change the definition of a sequence generator

## Synopsis

```
ALTER SEQUENCE name [ INCREMENT [ BY ] increment ]
    [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]
    [ RESTART [ WITH ] start ] [ CACHE cache ] [ [ NO ] CYCLE ]
    [ OWNED BY { table.column | NONE } ]
ALTER SEQUENCE name RENAME TO new_name
ALTER SEQUENCE name SET SCHEMA new_schema
```

## Description

ALTER SEQUENCE changes the parameters of an existing sequence generator. Any parameters not specifically set in the ALTER SEQUENCE command retain their prior settings.

You must own the sequence to use ALTER SEQUENCE. To change a sequence's schema, you must also have CREATE privilege on the new schema.

## Parameters

*name*

The name (optionally schema-qualified) of a sequence to be altered.

*increment*

The clause INCREMENT BY *increment* is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

*minvalue*

NO MINVALUE

The optional clause MINVALUE *minvalue* determines the minimum value a sequence can generate. If NO MINVALUE is specified, the defaults of 1 and  $-2^{63}-1$  for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

*maxvalue*

NO MAXVALUE

The optional clause MAXVALUE *maxvalue* determines the maximum value for the sequence. If NO MAXVALUE is specified, the defaults are  $2^{63}-1$  and  $-1$  for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

*start*

The optional clause RESTART WITH *start* changes the current value of the sequence. This is equivalent to calling the `setval` function with `is_called = false`: the specified value will be returned by the next call of `nextval`.

*cache*

The clause CACHE *cache* enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

CYCLE

The optional CYCLE key word can be used to enable the sequence to wrap around when the *maxvalue* or *minvalue* has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the *minvalue* or *maxvalue*, respectively.

NO CYCLE

If the optional NO CYCLE key word is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither CYCLE or NO CYCLE are specified, the old cycle behavior will be maintained.

OWNED BY *table.column*

OWNED BY NONE

The OWNED BY option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying OWNED BY NONE removes any existing association, making the sequence “free-standing”.

*new\_name*

The new name for the sequence.

*new\_schema*

The new schema for the sequence.

## Notes

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, ALTER SEQUENCE's effects on the sequence generation parameters are never rolled back; those changes take effect immediately and are not reversible. However, the OWNED BY, RENAME, and SET SCHEMA clauses cause ordinary catalog updates that can be rolled back.

`ALTER SEQUENCE` will not immediately affect `nextval` results in backends, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current backend will be affected immediately.

`ALTER SEQUENCE` does not affect the `currval` status for the sequence. (Before PostgreSQL 8.3, it sometimes did.)

Some variants of `ALTER TABLE` can be used with sequences as well; for example, to rename a sequence it is also possible to use `ALTER TABLE RENAME`.

## Examples

Restart a sequence called `serial`, at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

## Compatibility

`ALTER SEQUENCE` conforms to the SQL standard, except for the `OWNED BY`, `RENAME`, and `SET SCHEMA` clauses, which are PostgreSQL extensions.

## See Also

*CREATE SEQUENCE*, *DROP SEQUENCE*

# ALTER TABLE

## Name

ALTER TABLE — change the definition of a table

## Synopsis

```
ALTER TABLE [ ONLY ] name [ * ]
    action [, ... ]
ALTER TABLE [ ONLY ] name [ * ]
    RENAME [ COLUMN ] column TO new_column
ALTER TABLE name
    RENAME TO new_name

SET WITHOUT OIDS
SET ( storage_parameter = value [, ... ] )
RESET ( storage_parameter [, ... ] )
INHERIT parent_table
NO INHERIT parent_table
OWNER TO new_owner
SET TABLESPACE new_tablespace
```

## Description

`ALTER TABLE` changes the definition of an existing table. There are several subforms:

### `ADD COLUMN`

This form adds a new column to the table, using the same syntax as *CREATE TABLE*.

### `DROP COLUMN`

This form drops a column from a table. Indexes and table constraints involving the column will be automatically dropped as well. You will need to say *CASCADE* if anything outside the table depends on the column, for example, foreign key references or views.

### `ALTER COLUMN TYPE`

This form changes the type of a column of a table. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional *USING* clause specifies how to compute the new column value from the old; if omitted, the default conversion is the same as an assignment cast from old data type to new. A *USING* clause must be provided if there is no implicit or assignment cast from old to new type.

### `SET/DROP DEFAULT`

These forms set or remove the default value for a column. The default values only apply to subsequent *INSERT* commands; they do not cause rows already in the table to change. Defaults can also be created for views, in which case they are inserted into *INSERT* statements on the view before the view's *ON INSERT* rule is applied.

### `SET/DROP NOT NULL`

These forms change whether a column is marked to allow null values or to reject null values. You can only use *SET NOT NULL* when the column contains no null values.

### `SET STATISTICS`

This form sets the per-column statistics-gathering target for subsequent *ANALYZE* operations. The target can be set in the range 0 to 1000; alternatively, set it to -1 to revert to using the system default statistics target (*default\_statistics\_target*). For more information on the use of statistics by the PostgreSQL query planner, refer to Section 14.2.

### `SET STORAGE`

This form sets the storage mode for a column. This controls whether this column is held inline or in a supplementary table, and whether the data should be compressed or not. *PLAIN* must be used for fixed-length values such as *integer* and is inline, uncompressed. *MAIN* is for inline, compressible data. *EXTERNAL* is for external, uncompressed data, and *EXTENDED* is for external, compressed data. *EXTENDED* is the default for most data types that support non-*PLAIN* storage. Use of *EXTERNAL* will make substring operations on *text* and *bytea* columns faster, at the penalty of increased storage space. Note that *SET STORAGE* doesn't itself change anything in the table, it just sets the strategy to be pursued during future table updates. See Section 53.2 for more information.

### `ADD table_constraint`

This form adds a new constraint to a table using the same syntax as *CREATE TABLE*.

## DROP CONSTRAINT

This form drops the specified constraint on a table.

## DISABLE/ENABLE [ REPLICA | ALWAYS ] TRIGGER

These forms configure the firing of trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed. One can disable or enable a single trigger specified by name, or all triggers on the table, or only user triggers (this option excludes triggers that are used to implement foreign key constraints). Disabling or enabling constraint triggers requires superuser privileges; it should be done with caution since of course the integrity of the constraint cannot be guaranteed if the triggers are not executed. The trigger firing mechanism is also affected by the configuration variable `session_replication_role`. Simply enabled triggers will fire when the replication role is “origin” (the default) or “local”. Triggers configured `ENABLE REPLICA` will only fire if the session is in “replica” mode and triggers configured `ENABLE ALWAYS` will fire regardless of the current replication mode.

## DISABLE/ENABLE [ REPLICA | ALWAYS ] RULE

These forms configure the firing of rewrite rules belonging to the table. A disabled rule is still known to the system, but is not applied during query rewriting. The semantics are as for disabled/enabled triggers. This configuration is ignored for `ON SELECT` rules, which are always applied in order to keep views working even if the current session is in a non-default replication role.

## CLUSTER

This form selects the default index for future *CLUSTER* operations. It does not actually re-cluster the table.

## SET WITHOUT CLUSTER

This form removes the most recently used *CLUSTER* index specification from the table. This affects future cluster operations that don’t specify an index.

## SET WITHOUT OIDS

This form removes the `oid` system column from the table. This is exactly equivalent to `DROP COLUMN oid RESTRICT`, except that it will not complain if there is already no `oid` column.

Note that there is no variant of `ALTER TABLE` that allows OIDs to be restored to a table once they have been removed.

SET ( *storage\_parameter* = *value* [, ... ] )

This form changes one or more storage parameters for the table. See *CREATE TABLE* for details on the available parameters. Note that the table contents will not be modified immediately by this command; depending on the parameter you might need to rewrite the table to get the desired effects. That can be done with *CLUSTER* or one of the forms of `ALTER TABLE` that forces a table rewrite.

**Note:** While `CREATE TABLE` allows OIDS to be specified in the `WITH (storage_parameter)` syntax, `ALTER TABLE` does not treat OIDS as a storage parameter.

```
RESET ( storage_parameter [, ... ] )
```

This form resets one or more storage parameters to their defaults. As with `SET`, a table rewrite might be needed to update the table entirely.

```
INHERIT parent_table
```

This form adds the target table as a new child of the specified parent table. Subsequently, queries against the parent will include records of the target table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have `NOT NULL` constraints in the parent then they must also have `NOT NULL` constraints in the child.

There must also be matching child-table constraints for all `CHECK` constraints of the parent. Currently `UNIQUE`, `PRIMARY KEY`, and `FOREIGN KEY` constraints are not considered, but this might change in the future.

```
NO INHERIT parent_table
```

This form removes the target table from the list of children of the specified parent table. Queries against the parent table will no longer include records drawn from the target table.

```
OWNER
```

This form changes the owner of the table, sequence, or view to the specified user.

```
SET TABLESPACE
```

This form changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional `SET TABLESPACE` commands. See also *CREATE TABLESPACE*.

```
RENAME
```

The `RENAME` forms change the name of a table (or an index, sequence, or view) or the name of an individual column in a table. There is no effect on the stored data.

```
SET SCHEMA
```

This form moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.

All the actions except `RENAME` and `SET SCHEMA` can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use `ALTER TABLE`. To change the schema of a table, you must also have `CREATE` privilege on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.)

## Parameters

*name*

The name (possibly schema-qualified) of an existing table to alter. If `ONLY` is specified, only that table is altered. If `ONLY` is not specified, the table and all its descendant tables (if any) are updated. `*` can be appended to the table name to indicate that descendant tables are to be altered, but in the current version, this is the default behavior. (In releases before 7.1, `ONLY` was the default behavior. The default can be altered by changing the configuration parameter `sql_inheritance`.)

*column*

Name of a new or existing column.

*new\_column*

New name for an existing column.

*new\_name*

New name for the table.

*type*

Data type of the new column, or new data type for an existing column.

*table\_constraint*

New table constraint for the table.

*constraint\_name*

Name of an existing constraint to drop.

CASCADE

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column).

RESTRICT

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

*trigger\_name*

Name of a single trigger to disable or enable.

ALL

Disable or enable all triggers belonging to the table. (This requires superuser privilege if any of the triggers are for foreign key constraints.)

USER

Disable or enable all triggers belonging to the table except for foreign key constraint triggers.

*index\_name*

The index name on which the table should be marked for clustering.

*storage\_parameter*

The name of a table storage parameter.

*value*

The new value for a table storage parameter. This might be a number or a word depending on the parameter.

*parent\_table*

A parent table to associate or de-associate with this table.

*new\_owner*

The user name of the new owner of the table.

*new\_tablespace*

The name of the tablespace to which the table will be moved.

*new\_schema*

The name of the schema to which the table will be moved.

## Notes

The key word `COLUMN` is noise and can be omitted.

When a column is added with `ADD COLUMN`, all existing rows in the table are initialized with the column's default value (NULL if no `DEFAULT` clause is specified).

Adding a column with a non-null default or changing the type of an existing column will require the entire table to be rewritten. This might take a significant amount of time for a large table; and it will temporarily require double the disk space.

Adding a `CHECK` or `NOT NULL` constraint requires scanning the table to verify that existing rows meet the constraint.

The main reason for providing the option to specify multiple changes in a single `ALTER TABLE` is that multiple table scans or rewrites can thereby be combined into a single pass over the table.

The `DROP COLUMN` form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated.

The fact that `ALTER TYPE` requires rewriting the whole table is sometimes an advantage, because the rewriting process eliminates any dead space in the table. For example, to reclaim the space occupied by a dropped column immediately, the fastest way is:

```
ALTER TABLE table ALTER COLUMN anycol TYPE anytype;
```

where `anycol` is any remaining table column and `anytype` is the same type that column already has. This results in no semantically-visible change in the table, but the command forces rewriting, which gets rid of no-longer-useful data.

The `USING` option of `ALTER TYPE` can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the `ALTER TYPE` syntax. Because of this flexibility, the `USING` expression is

not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, `ALTER TYPE` might fail to convert the default even though a `USING` clause is supplied. In such cases, drop the default with `DROP DEFAULT`, perform the `ALTER TYPE`, and then use `SET DEFAULT` to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

If a table has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. That is, `ALTER TABLE ONLY` will be rejected. This ensures that the descendants always have columns matching the parent.

A recursive `DROP COLUMN` operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN` (i.e., `ALTER TABLE ONLY ... DROP COLUMN`) never removes any descendant columns, but instead marks them as independently defined rather than inherited.

The `TRIGGER`, `CLUSTER`, `OWNER`, and `TABLESPACE` actions never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Adding a constraint can recurse only for `CHECK` constraints.

Changing any part of a system catalog table is not permitted.

Refer to *CREATE TABLE* for a further description of valid parameters. Chapter 5 has further information on inheritance.

## Examples

To add a column of type `varchar` to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

To drop a column from a table:

```
ALTER TABLE distributors DROP COLUMN address RESTRICT;
```

To change the types of two existing columns in one operation:

```
ALTER TABLE distributors
    ALTER COLUMN address TYPE varchar(80),
    ALTER COLUMN name TYPE varchar(100);
```

To change an integer column containing UNIX timestamps to timestamp with time zone via a `USING` clause:

```
ALTER TABLE foo
    ALTER COLUMN foo_timestamp TYPE timestamp with time zone
    USING
        timestamp with time zone 'epoch' + foo_timestamp * interval '1 second';
```

The same, when the column has a default expression that won't automatically cast to the new data type:

```
ALTER TABLE foo
  ALTER COLUMN foo_timestamp DROP DEFAULT,
  ALTER COLUMN foo_timestamp TYPE timestamp with time zone
  USING
    timestamp with time zone 'epoch' + foo_timestamp * interval '1 second',
  ALTER COLUMN foo_timestamp SET DEFAULT now();
```

To rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

To rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

To add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

To remove a not-null constraint from a column:

```
ALTER TABLE distributors ALTER COLUMN street DROP NOT NULL;
```

To add a check constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5);
```

To remove a check constraint from a table and all its children:

```
ALTER TABLE distributors DROP CONSTRAINT zipchk;
```

To add a foreign key constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT distfk FOREIGN KEY (address) REFERENCES addresses (
```

To add a (multicolumn) unique constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT dist_id_zipcode_key UNIQUE (dist_id, zipcode);
```

To add an automatically named primary key constraint to a table, noting that a table can only ever have one primary key:

```
ALTER TABLE distributors ADD PRIMARY KEY (dist_id);
```

To move a table to a different tablespace:

```
ALTER TABLE distributors SET TABLESPACE fasttablespace;
```

To move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

## Compatibility

The `ADD`, `DROP`, and `SET DEFAULT` forms conform with the SQL standard. The other forms are PostgreSQL extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single `ALTER TABLE` command is an extension.

`ALTER TABLE DROP COLUMN` can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

# ALTER TABLESPACE

## Name

ALTER TABLESPACE — change the definition of a tablespace

## Synopsis

```
ALTER TABLESPACE name RENAME TO newname
ALTER TABLESPACE name OWNER TO newowner
```

## Description

ALTER TABLESPACE changes the definition of a tablespace.

You must own the tablespace to use ALTER TABLESPACE. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

## Parameters

*name*

The name of an existing tablespace.

*newname*

The new name of the tablespace. The new name cannot begin with `pg_`, as such names are reserved for system tablespaces.

*newowner*

The new owner of the tablespace.

## Examples

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

## **Compatibility**

There is no `ALTER TABLESPACE` statement in the SQL standard.

## **See Also**

*CREATE TABLESPACE, DROP TABLESPACE*

# ALTER TEXT SEARCH CONFIGURATION

## Name

ALTER TEXT SEARCH CONFIGURATION — change the definition of a text search configuration

## Synopsis

```
ALTER TEXT SEARCH CONFIGURATION name
    ADD MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] WITH dictionary_name [, ... ]
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    ALTER MAPPING FOR token_type [, ... ] REPLACE old_dictionary WITH new_dictionary
ALTER TEXT SEARCH CONFIGURATION name
    DROP MAPPING [ IF EXISTS ] FOR token_type [, ... ]
ALTER TEXT SEARCH CONFIGURATION name RENAME TO newname
ALTER TEXT SEARCH CONFIGURATION name OWNER TO newowner
```

## Description

ALTER TEXT SEARCH CONFIGURATION changes the definition of a text search configuration. You can modify its mappings from token types to dictionaries, or change the configuration's name or owner.

You must be the owner of the configuration to use ALTER TEXT SEARCH CONFIGURATION.

## Parameters

*name*

The name (optionally schema-qualified) of an existing text search configuration.

*token\_type*

The name of a token type that is emitted by the configuration's parser.

*dictionary\_name*

The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

*old\_dictionary*

The name of a text search dictionary to be replaced in the mapping.

*new\_dictionary*

The name of a text search dictionary to be substituted for *old\_dictionary*.

*newname*

The new name of the text search configuration.

*newowner*

The new owner of the text search configuration.

The `ADD MAPPING FOR` form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The `ALTER MAPPING FOR` form does the same, but first removing any existing mapping for those token types. The `ALTER MAPPING REPLACE` forms substitute *new\_dictionary* for *old\_dictionary* anywhere the latter appears. This is done for only the specified token types when `FOR` appears, or for all mappings of the configuration when it doesn't. The `DROP MAPPING` form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless `IF EXISTS` appears.

## Examples

The following example replaces the `english` dictionary with the `swedish` dictionary anywhere that `english` is used within `my_config`.

```
ALTER TEXT SEARCH CONFIGURATION my_config
    ALTER MAPPING REPLACE english WITH swedish;
```

## Compatibility

There is no `ALTER TEXT SEARCH CONFIGURATION` statement in the SQL standard.

## See Also

*CREATE TEXT SEARCH CONFIGURATION*, *DROP TEXT SEARCH CONFIGURATION*

# ALTER TEXT SEARCH DICTIONARY

## Name

ALTER TEXT SEARCH DICTIONARY — change the definition of a text search dictionary

## Synopsis

```
ALTER TEXT SEARCH DICTIONARY name (  
    option [ = value ] [, ... ]  
)  
ALTER TEXT SEARCH DICTIONARY name RENAME TO newname  
ALTER TEXT SEARCH DICTIONARY name OWNER TO newowner
```

## Description

ALTER TEXT SEARCH DICTIONARY changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use ALTER TEXT SEARCH DICTIONARY.

## Parameters

*name*

The name (optionally schema-qualified) of an existing text search dictionary.

*option*

The name of a template-specific option to be set for this dictionary.

*value*

The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

*newname*

The new name of the text search dictionary.

*newowner*

The new owner of the text search dictionary.

Template-specific options can appear in any order.

## Examples

The following example command changes the stopword list for a Snowball-based dictionary. Other parameters remain unchanged.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );
```

The following example command changes the language option to dutch, and removes the stopword option entirely.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );
```

The following example command “updates” the dictionary’s definition without actually changing anything.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );
```

(The reason this works is that the option removal code doesn’t complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the `ALTER` will force existing database sessions to re-read the configuration files, which otherwise they would never do if they had read them earlier.

## Compatibility

There is no `ALTER TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

*CREATE TEXT SEARCH DICTIONARY, DROP TEXT SEARCH DICTIONARY*

# ALTER TEXT SEARCH PARSER

## Name

ALTER TEXT SEARCH PARSER — change the definition of a text search parser

## Synopsis

```
ALTER TEXT SEARCH PARSER name RENAME TO newname
```

## Description

ALTER TEXT SEARCH PARSER changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use ALTER TEXT SEARCH PARSER.

## Parameters

*name*

The name (optionally schema-qualified) of an existing text search parser.

*newname*

The new name of the text search parser.

## Compatibility

There is no ALTER TEXT SEARCH PARSER statement in the SQL standard.

## See Also

CREATE TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER

# ALTER TEXT SEARCH TEMPLATE

## Name

ALTER TEXT SEARCH TEMPLATE — change the definition of a text search template

## Synopsis

```
ALTER TEXT SEARCH TEMPLATE name RENAME TO newname
```

## Description

ALTER TEXT SEARCH TEMPLATE changes the definition of a text search template. Currently, the only supported functionality is to change the template's name.

You must be a superuser to use ALTER TEXT SEARCH TEMPLATE.

## Parameters

*name*

The name (optionally schema-qualified) of an existing text search template.

*newname*

The new name of the text search template.

## Compatibility

There is no ALTER TEXT SEARCH TEMPLATE statement in the SQL standard.

## See Also

CREATE TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE

# ALTER TRIGGER

## Name

ALTER TRIGGER — change the definition of a trigger

## Synopsis

```
ALTER TRIGGER name ON table RENAME TO newname
```

## Description

ALTER TRIGGER changes properties of an existing trigger. The RENAME clause changes the name of the given trigger without otherwise changing the trigger definition.

You must own the table on which the trigger acts to be allowed to change its properties.

## Parameters

*name*

The name of an existing trigger to alter.

*table*

The name of the table on which this trigger acts.

*newname*

The new name for the trigger.

## Notes

The ability to temporarily enable or disable a trigger is provided by *ALTER TABLE*, not by ALTER TRIGGER, because ALTER TRIGGER has no convenient way to express the option of enabling or disabling all of a table's triggers at once.

## Examples

To rename an existing trigger:

```
ALTER TRIGGER emp_stamp ON emp RENAME TO emp_track_chgs;
```

## **Compatibility**

`ALTER TRIGGER` is a PostgreSQL extension of the SQL standard.

## **See Also**

*ALTER TABLE*

# ALTER TYPE

## Name

ALTER TYPE — change the definition of a type

## Synopsis

```
ALTER TYPE name OWNER TO new_owner
ALTER TYPE name SET SCHEMA new_schema
```

## Description

ALTER TYPE changes the definition of an existing type. The only currently available capabilities are changing the owner and schema of a type.

You must own the type to use ALTER TYPE. To change the schema of a type, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the type's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the type. However, a superuser can alter ownership of any type anyway.)

## Parameters

*name*

The name (possibly schema-qualified) of an existing type to alter.

*new\_owner*

The user name of the new owner of the type.

*new\_schema*

The new schema for the type.

## Examples

To change the owner of the user-defined type `email` to `joe`:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type `email` to `customers`:

```
ALTER TYPE email SET SCHEMA customers;
```

## Compatibility

There is no `ALTER TYPE` statement in the SQL standard.

# ALTER USER

## Name

ALTER USER — change a database role

## Synopsis

```
ALTER USER name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
```

```
ALTER USER name RENAME TO newname
```

```
ALTER USER name SET configuration_parameter { TO | = } { value | DEFAULT }
```

```
ALTER USER name SET configuration_parameter FROM CURRENT
```

```
ALTER USER name RESET configuration_parameter
```

```
ALTER USER name RESET ALL
```

## Description

ALTER USER is now an alias for *ALTER ROLE*.

## Compatibility

The ALTER USER statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

## See Also

*ALTER ROLE*

# ALTER VIEW

## Name

ALTER VIEW — change the definition of a view

## Synopsis

```
ALTER VIEW name RENAME TO newname
```

## Description

ALTER VIEW changes the definition of a view. The only currently available functionality is to rename the view. To execute this command you must be the owner of the view.

## Parameters

*name*

The name (optionally schema-qualified) of an existing view.

*newname*

The new name of the view.

## Notes

Some variants of ALTER TABLE can be used with views as well; for example, to rename a view it is also possible to use ALTER TABLE RENAME. To change the schema or owner of a view, you currently must use ALTER TABLE.

## Examples

To rename the view `foo` to `bar`:

```
ALTER VIEW foo RENAME TO bar;
```

## Compatibility

ALTER VIEW is a PostgreSQL extension of the SQL standard.

## **See Also**

*CREATE VIEW, DROP VIEW*

# ANALYZE

## Name

`ANALYZE` — collect statistics about a database

## Synopsis

```
ANALYZE [ VERBOSE ] [ table [ ( column [, ...] ) ] ]
```

## Description

`ANALYZE` collects statistics about the contents of tables in the database, and stores the results in the `pg_statistic` system catalog. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

With no parameter, `ANALYZE` examines every table in the current database. With a parameter, `ANALYZE` examines only that table. It is further possible to give a list of column names, in which case only the statistics for those columns are collected.

## Parameters

`VERBOSE`

Enables display of progress messages.

*table*

The name (possibly schema-qualified) of a specific table to analyze. Defaults to all tables in the current database.

*column*

The name of a specific column to analyze. Defaults to all columns.

## Outputs

When `VERBOSE` is specified, `ANALYZE` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

## Notes

In the default PostgreSQL configuration, *The Auto-Vacuum Daemon* takes care of automatic analyzing of tables when they are first loaded with data, and as they change throughout regular operation. When autovacuum is disabled, it is a good idea to run `ANALYZE` periodically, or just after making major changes

in the contents of a table. Accurate statistics will help the planner to choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy is to run *VACUUM* and *ANALYZE* once a day during a low-usage time of day.

*ANALYZE* requires only a read lock on the target table, so it can run in parallel with other activity on the table.

The statistics collected by *ANALYZE* usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these can be omitted if *ANALYZE* deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators. There is more information about the statistics in Chapter 23.

For large tables, *ANALYZE* takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time *ANALYZE* is run, even if the actual table contents did not change. This might result in small changes in the planner's estimated costs shown by *EXPLAIN*. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of *ANALYZE*. To avoid this, raise the amount of statistics collected by *ANALYZE*, as described below.

The extent of analysis can be controlled by adjusting the `default_statistics_target` configuration variable, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS` (see *ALTER TABLE*). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 10, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for *ANALYZE* and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero disables collection of statistics for that column. It might be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do *ANALYZE*.

## Compatibility

There is no *ANALYZE* statement in the SQL standard.

## See Also

*VACUUM*, *vacuumdb*, *Cost-Based Vacuum Delay*, *The Auto-Vacuum Daemon*

# BEGIN

## Name

BEGIN — start a transaction block

## Synopsis

```
BEGIN [ WORK | TRANSACTION ] [ transaction_mode [, ...] ]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED }  
READ WRITE | READ ONLY
```

## Description

BEGIN initiates a transaction block, that is, all statements after a BEGIN command will be executed in a single transaction until an explicit *COMMIT* or *ROLLBACK* is given. By default (without BEGIN), PostgreSQL executes transactions in “autocommit” mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if *SET TRANSACTION* was executed.

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

Refer to *SET TRANSACTION* for information on the meaning of the other parameters to this statement.

## Notes

*START TRANSACTION* has the same functionality as BEGIN.

Use *COMMIT* or *ROLLBACK* to terminate a transaction block.

Issuing `BEGIN` when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see *SAVEPOINT*).

For reasons of backwards compatibility, the commas between successive *transaction\_modes* can be omitted.

## Examples

To begin a transaction block:

```
BEGIN;
```

## Compatibility

`BEGIN` is a PostgreSQL language extension. It is equivalent to the SQL-standard command *START TRANSACTION*, whose reference page contains additional compatibility information.

Incidentally, the `BEGIN` key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

## See Also

*COMMIT*, *ROLLBACK*, *START TRANSACTION*, *SAVEPOINT*

# CHECKPOINT

## Name

`CHECKPOINT` — force a transaction log checkpoint

## Synopsis

`CHECKPOINT`

## Description

Write-Ahead Logging (WAL) puts a checkpoint in the transaction log every so often. (To adjust the automatic checkpoint interval, see the run-time configuration options `checkpoint_segments` and `checkpoint_timeout`.) The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a scheduled checkpoint.

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk. Refer to Chapter 28 for more information about the WAL system.

Only superusers can call `CHECKPOINT`. The command is not intended for use during normal operation.

## Compatibility

The `CHECKPOINT` command is a PostgreSQL language extension.

# CLOSE

## Name

CLOSE — close a cursor

## Synopsis

```
CLOSE { name | ALL }
```

## Description

CLOSE frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by COMMIT or ROLLBACK. A holdable cursor is implicitly closed if the transaction that created it aborts via ROLLBACK. If the creating transaction successfully commits, the holdable cursor remains open until an explicit CLOSE is executed, or the client disconnects.

## Parameters

*name*

The name of an open cursor to close.

ALL

Close all open cursors.

## Notes

PostgreSQL does not have an explicit OPEN cursor statement; a cursor is considered open when it is declared. Use the *DECLARE* statement to declare a cursor.

You can see all available cursors by querying the `pg_cursors` system view.

## Examples

Close the cursor `liahona`:

```
CLOSE liahona;
```

## Compatibility

`CLOSE` is fully conforming with the SQL standard. `CLOSE ALL` is a PostgreSQL extension.

*DECLARE, FETCH, MOVE*

# CLUSTER

## Name

CLUSTER — cluster a table according to an index

## Synopsis

```
CLUSTER tablename [ USING indexname ]  
CLUSTER
```

## Description

CLUSTER instructs PostgreSQL to cluster the table specified by *tablename* based on the index specified by *indexname*. The index must already have been defined on *tablename*.

When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. (If one wishes, one can periodically recluster by issuing the command again. Also, setting the table's `FILLFACTOR` storage parameter to less than 100% can aid in preserving cluster ordering during updates, since updated rows are preferentially kept on the same page.)

When a table is clustered, PostgreSQL remembers which index it was clustered by. The form `CLUSTER tablename` reclusters the table using the same index as before.

CLUSTER without any parameter reclusters all the previously-clustered tables in the current database that the calling user owns, or all such tables if called by a superuser. This form of CLUSTER cannot be executed inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the CLUSTER is finished.

## Parameters

*tablename*

The name (possibly schema-qualified) of a table.

*indexname*

The name of an index.

## Notes

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an

index that groups them together, you will benefit from using `CLUSTER`. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

During the cluster operation, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

Because `CLUSTER` remembers the clustering information, one can cluster the tables one wants clustered manually the first time, and setup a timed event similar to `VACUUM` so that the tables are periodically reclustered.

Because the planner records statistics about the ordering of tables, it is advisable to run `ANALYZE` on the newly clustered table. Otherwise, the planner might make poor choices of query plans.

There is another way to cluster data. The `CLUSTER` command reorders the original table by scanning it using the index you specify. This can be slow on large tables because the rows are fetched from the table in index order, and if the table is disordered, the entries are on random pages, so there is one disk page retrieved for every row moved. (PostgreSQL has a cache, but the majority of a big table will not fit in the cache.) The other way to cluster a table is to use:

```
CREATE TABLE newtable AS
SELECT * FROM table ORDER BY columnlist;
```

which uses the PostgreSQL sorting code to produce the desired order; this is usually much faster than an index scan for disordered data. Then you drop the old table, use `ALTER TABLE ... RENAME` to rename `newtable` to the old name, and recreate the table's indexes. The big disadvantage of this approach is that it does not preserve OIDs, constraints, foreign key relationships, granted privileges, and other ancillary properties of the table — all such items must be manually recreated. Another disadvantage is that this way requires a sort temporary file about the same size as the table itself, so peak disk usage is about three times the table size instead of twice the table size.

## Examples

Cluster the table `employees` on the basis of its index `employees_ind`:

```
CLUSTER employees USING employees_ind;
```

Cluster the `employees` table using the same index that was used before:

```
CLUSTER employees;
```

Cluster all tables in the database that have previously been clustered:

```
CLUSTER;
```

## Compatibility

There is no `CLUSTER` statement in the SQL standard.

The syntax

```
CLUSTER indexname ON tablename
```

is also supported for compatibility with pre-8.3 PostgreSQL versions.

# COMMENT

## Name

COMMENT — define or change the comment of an object

## Synopsis

```
COMMENT ON
{
    TABLE object_name |
    COLUMN table_name.column_name |
    AGGREGATE agg_name (agg_type [, ...] ) |
    CAST (sourcetype AS targettype) |
    CONSTRAINT constraint_name ON table_name |
    CONVERSION object_name |
    DATABASE object_name |
    DOMAIN object_name |
    FUNCTION func_name ( [ [ argmode ] [ argname ] argtype [, ...] ] ) |
    INDEX object_name |
    LARGE OBJECT large_object_oid |
    OPERATOR op (leftoperand_type, rightoperand_type) |
    OPERATOR CLASS object_name USING index_method |
    OPERATOR FAMILY object_name USING index_method |
    [ PROCEDURAL ] LANGUAGE object_name |
    ROLE object_name |
    RULE rule_name ON table_name |
    SCHEMA object_name |
    SEQUENCE object_name |
    TABLESPACE object_name |
    TEXT SEARCH CONFIGURATION object_name |
    TEXT SEARCH DICTIONARY object_name |
    TEXT SEARCH PARSER object_name |
    TEXT SEARCH TEMPLATE object_name |
    TRIGGER trigger_name ON table_name |
    TYPE object_name |
    VIEW object_name
} IS 'text'
```

## Description

COMMENT stores a comment about a database object.

To modify a comment, issue a new COMMENT command for the same object. Only one comment string is stored for each object. To remove a comment, write NULL in place of the text string. Comments are automatically dropped when the object is dropped.

Comments can be viewed using psql's \d family of commands. Other user interfaces to retrieve comments can be built atop the same built-in functions that psql uses, namely `obj_description`, `col_description`, and `shobj_description` (see Table 9-48).

## Parameters

*object\_name*  
*table\_name.column\_name*  
*agg\_name*  
*constraint\_name*  
*func\_name*  
*op*  
*rule\_name*  
*trigger\_name*

The name of the object to be commented. Names of tables, aggregates, domains, functions, indexes, operators, operator classes, operator families, sequences, text search objects, types, and views can be schema-qualified.

*agg\_type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of input data types.

*sourcetype*

The name of the source data type of the cast.

*targettype*

The name of the target data type of the cast.

*argmode*

The mode of a function argument: either `IN`, `OUT`, or `INOUT`. If omitted, the default is `IN`. Note that `COMMENT ON FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN` and `INOUT` arguments.

*argname*

The name of a function argument. Note that `COMMENT ON FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any.

*large\_object\_oid*

The OID of the large object.

PROCEDURAL

This is a noise word.

*text*

The new comment, written as a string literal; or NULL to drop the comment.

## Notes

There is presently no security mechanism for comments: any user connected to a database can see all the comments for objects in that database (although only superusers can change comments for objects that they don't own). For shared objects such as databases, roles, and tablespaces comments are stored globally and any user connected to any database can see all the comments for shared objects. Therefore, don't put security-critical information in comments.

## Examples

Attach a comment to the table mytable:

```
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```
COMMENT ON TABLE mytable IS NULL;
```

Some more examples:

```
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON LARGE OBJECT 346344 IS 'Planning document';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, text) IS 'This is a prefix operator on text';
COMMENT ON OPERATOR CLASS int4ops USING btree IS '4 byte integer operators for btrees';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for btrees';
COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
```

```
COMMENT ON TYPE complex IS 'Complex number data type';  
COMMENT ON VIEW my_view IS 'View of departmental costs';
```

## **Compatibility**

There is no `COMMENT` command in the SQL standard.

# COMMIT

## Name

COMMIT — commit the current transaction

## Synopsis

COMMIT [ WORK | TRANSACTION ]

## Description

COMMIT commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

## Parameters

WORK

TRANSACTION

Optional key words. They have no effect.

## Notes

Use *ROLLBACK* to abort a transaction.

Issuing COMMIT when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

## Compatibility

The SQL standard only specifies the two forms COMMIT and COMMIT WORK. Otherwise, this command is fully conforming.

## **See Also**

*BEGIN, ROLLBACK*

# COMMIT PREPARED

## Name

`COMMIT PREPARED` — commit a transaction that was earlier prepared for two-phase commit

## Synopsis

```
COMMIT PREPARED transaction_id
```

## Description

`COMMIT PREPARED` commits a transaction that is in prepared state.

## Parameters

*transaction\_id*

The transaction identifier of the transaction that is to be committed.

## Notes

To commit a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is committed immediately.

All currently available prepared transactions are listed in the `pg_prepared_xacts` system view.

## Examples

Commit the transaction identified by the transaction identifier `foobar`:

```
COMMIT PREPARED 'foobar';
```

## See Also

*PREPARE TRANSACTION*, *ROLLBACK PREPARED*

# COPY

## Name

COPY — copy data between a file and a table

## Synopsis

```
COPY tablename [ ( column [, ...] ) ]
FROM { 'filename' | STDIN }
[ [ WITH ]
    [ BINARY ]
    [ OIDS ]
    [ DELIMITER [ AS ] 'delimiter' ]
    [ NULL [ AS ] 'null string' ]
    [ CSV [ HEADER ]
        [ QUOTE [ AS ] 'quote' ]
        [ ESCAPE [ AS ] 'escape' ]
        [ FORCE NOT NULL column [, ...] ]
    ]
]

COPY { tablename [ ( column [, ...] ) ] | ( query ) }
TO { 'filename' | STDOUT }
[ [ WITH ]
    [ BINARY ]
    [ HEADER ]
    [ OIDS ]
    [ DELIMITER [ AS ] 'delimiter' ]
    [ NULL [ AS ] 'null string' ]
    [ CSV [ HEADER ]
        [ QUOTE [ AS ] 'quote' ]
        [ ESCAPE [ AS ] 'escape' ]
        [ FORCE QUOTE column [, ...] ]
    ]
]
```

## Description

COPY moves data between PostgreSQL tables and standard file-system files. COPY TO copies the contents of a table *to* a file, while COPY FROM copies data *from* a file to a table (appending the data to whatever is in the table already). COPY TO can also copy the results of a SELECT query.

If a list of columns is specified, COPY will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, COPY FROM will insert the default values for those columns.

COPY with a file name instructs the PostgreSQL server to directly read from or write to a file. The file must be accessible to the server and the name must be specified from the viewpoint of the server. When STDIN or STDOUT is specified, data is transmitted via the connection between the client and the server.

## Parameters

*tablename*

The name (optionally schema-qualified) of an existing table.

*column*

An optional list of columns to be copied. If no column list is specified, all columns of the table will be copied.

*query*

A *SELECT* or *VALUES* command whose results are to be copied. Note that parentheses are required around the query.

*filename*

The absolute path name of the input or output file. Windows users might need to use an `E"` string and double backslashes used as path separators.

STDIN

Specifies that input comes from the client application.

STDOUT

Specifies that output goes to the client application.

BINARY

Causes all data to be stored or read in binary format rather than as text. You cannot specify the *DELIMITER*, *NULL*, or *CSV* options in binary mode.

OIDS

Specifies copying the OID for each row. (An error is raised if *OIDS* is specified for a table that does not have OIDs, or in the case of copying a *query*.)

*delimiter*

The single ASCII character that separates columns within each row (line) of the file. The default is a tab character in text mode, a comma in *CSV* mode.

*null string*

The string that represents a null value. The default is `\N` (backslash-N) in text mode, and an empty value with no quotes in *CSV* mode. You might prefer an empty string even in text mode for cases where you don't want to distinguish nulls from empty strings.

**Note:** When using `COPY FROM`, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with `COPY TO`.

CSV

Selects Comma Separated Value (*CSV*) mode.

**HEADER**

Specifies the file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored.

*quote*

Specifies the ASCII quotation character in CSV mode. The default is double-quote.

*escape*

Specifies the ASCII character that should appear before a `QUOTE` data character value in CSV mode. The default is the `QUOTE` value (usually double-quote).

**FORCE QUOTE**

In CSV `COPY TO` mode, forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted.

**FORCE NOT NULL**

In CSV `COPY FROM` mode, process each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (`"`), this causes missing values to be input as zero-length strings.

## Outputs

On successful completion, a `COPY` command returns a command tag of the form

`COPY count`

The *count* is the number of rows copied.

## Notes

`COPY` can only be used with plain tables, not with views. However, you can write `COPY (SELECT * FROM viewname) TO ....`

The `BINARY` key word causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and PostgreSQL versions.

You must have select privilege on the table whose values are read by `COPY TO`, and insert privilege on the table into which values are inserted by `COPY FROM`.

Files named in a `COPY` command are read or written directly by the server, not by the client application. Therefore, they must reside on or be accessible to the database server machine, not the client. They must be accessible to and readable or writable by the PostgreSQL user (the user ID the server runs as), not the client. `COPY` naming a file is only allowed to database superusers, since it allows reading or writing any file that the server has privileges to access.

Do not confuse `COPY` with the `psql` instruction `\copy`. `\copy` invokes `COPY FROM STDIN` or `COPY TO STDOUT`, and then fetches/stores the data in a file accessible to the `psql` client. Thus, file accessibility and access rights depend on the client rather than the server when `\copy` is used.

It is recommended that the file name used in `COPY` always be specified as an absolute path. This is enforced by the server in the case of `COPY TO`, but for `COPY FROM` you do have the option of reading from a file specified by a relative path. The path will be interpreted relative to the working directory of the server process (normally the cluster's data directory), not the client's working directory.

`COPY FROM` will invoke any triggers and check constraints on the destination table. However, it will not invoke rules.

`COPY` input and output is affected by `DateStyle`. To ensure portability to other PostgreSQL installations that might use non-default `DateStyle` settings, `DateStyle` should be set to `ISO` before using `COPY TO`.

Input data is interpreted according to the current client encoding, and output data is encoded in the the current client encoding, even if the data does not pass through the client but is read from or written to a file.

`COPY` stops operation at the first error. This should not lead to problems in the event of a `COPY TO`, but the target table will already have received earlier rows in a `COPY FROM`. These rows will not be visible or accessible, but they still occupy disk space. This might amount to a considerable amount of wasted disk space if the failure happened well into a large copy operation. You might wish to invoke `VACUUM` to recover the wasted space.

## File Formats

### Text Format

When `COPY` is used without the `BINARY` or `CSV` options, the data read or written is a text file with one line per table row. Columns in a row are separated by the delimiter character. The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. `COPY FROM` will raise an error if any line of the input file contains more or fewer columns than are expected. If `OIDS` is specified, the OID is read or written as the first column, preceding the user data columns.

End of data can be represented by a single line containing just backslash-period (`\.`). An end-of-data marker is not necessary when reading from a file, since the end of file serves perfectly well; it is needed only when copying data to or from client applications using pre-3.0 client protocol.

Backslash characters (`\`) can be used in the `COPY` data to quote data characters that might otherwise be taken as row or column delimiters. In particular, the following characters *must* be preceded by a backslash if they appear as part of a column value: backslash itself, newline, carriage return, and the current delimiter character.

The specified null string is sent by `COPY TO` without adding any backslashes; conversely, `COPY FROM` matches the input against the null string before removing backslashes. Therefore, a null string such as `\N` cannot be confused with the actual data value `\N` (which would be represented as `\\N`).

The following special backslash sequences are recognized by `COPY FROM`:

Sequence	Represents
<code>\b</code>	Backspace (ASCII 8)
<code>\f</code>	Form feed (ASCII 12)

Sequence	Represents
<code>\n</code>	Newline (ASCII 10)
<code>\r</code>	Carriage return (ASCII 13)
<code>\t</code>	Tab (ASCII 9)
<code>\v</code>	Vertical tab (ASCII 11)
<code>\digits</code>	Backslash followed by one to three octal digits specifies the character with that numeric code
<code>\xdigits</code>	Backslash x followed by one or two hex digits specifies the character with that numeric code

Presently, COPY TO will never emit an octal or hex-digits backslash sequence, but it does use the other sequences listed above for those control characters.

Any other backslashed character that is not mentioned in the above table will be taken to represent itself. However, beware of adding backslashes unnecessarily, since that might accidentally produce a string matching the end-of-data marker (`\.`) or the null string (`\N` by default). These strings will be recognized before any other backslash processing is done.

It is strongly recommended that applications generating COPY data convert data newlines and carriage returns to the `\n` and `\r` sequences respectively. At present it is possible to represent a data carriage return by a backslash and carriage return, and to represent a data newline by a backslash and newline. However, these representations might not be accepted in future releases. They are also highly vulnerable to corruption if the COPY file is transferred across different machines (for example, from Unix to Windows or vice versa).

COPY TO will terminate each row with a Unix-style newline ("`\n`"). Servers running on Microsoft Windows instead output carriage return/newline ("`\r\n`"), but only for COPY to a server file; for consistency across platforms, COPY TO STDOUT always sends "`\n`" regardless of server platform. COPY FROM can handle lines ending with newlines, carriage returns, or carriage return/newlines. To reduce the risk of error due to un-backslashed newlines or carriage returns that were meant as data, COPY FROM will complain if the line endings in the input are not all alike.

## CSV Format

This format is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping used by PostgreSQL's standard text mode, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character, and any occurrence within the value of a `QUOTE` character or the `ESCAPE` character is preceded by the escape character. You can also use `FORCE QUOTE` to force quotes when outputting non-NULL values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. PostgreSQL's COPY handles this by quoting. A `NULL` is output as the `NULL` string and is not quoted, while a data value matching the `NULL` string is quoted. Therefore, using the default settings, a `NULL` is written as an unquoted empty string, while an empty string is written with double quotes ("`''`"). Reading values follows similar rules. You can use `FORCE NOT NULL` to prevent `NULL` input comparisons for specific columns.

Because backslash is not a special character in the CSV format, `\.`, the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a `\.` data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of `\.`, you might need to quote that value in the input file.

**Note:** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into PostgreSQL.

**Note:** CSV mode will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-mode files.

**Note:** Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and COPY might produce files that other programs cannot process.

## Binary Format

The file format used for COPY BINARY changed in PostgreSQL 7.4. The new format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are now in network byte order.

### File Header

The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:

#### Signature

11-byte sequence `PGCOPY\0377\0\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)

#### Flags field

32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal

backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag bit is defined, and the rest must be zero:

#### Bit 16

if 1, OIDs are included in the data; if 0, not

#### Header extension area length

32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know what to do with.

The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.

This design allows for both backwards-compatible header additions (add header extension chunks, or set low-order flag bits) and non-backwards-compatible changes (set high-order flag bits to signal such changes, and add supporting data to the extension area if needed).

### *Tuples*

Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a `COPY BINARY` file are assumed to be in binary format (format code one). It is anticipated that a future extension might add a header field that allows per-column format codes to be specified.

To determine the appropriate binary format for the actual tuple data you should consult the PostgreSQL source, in particular the `*send` and `*recv` functions for each column's data type (typically these functions are found in the `src/backend/utils/adt/` directory of the source distribution).

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it's not included in the field-count. In particular it has a length word — this will allow handling of 4-byte vs. 8-byte OIDs without too much pain, and will allow OIDs to be shown as null if that ever proves desirable.

### *File Trailer*

The file trailer consists of a 16-bit integer word containing -1. This is easily distinguished from a tuple's field-count word.

A reader should report an error if a field-count word is neither -1 nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

## Examples

The following example copies a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT WITH DELIMITER '|';
```

To copy data from a file into the `country` table:

```
COPY country FROM '/usr1/proj/bray/sql/country_data';
```

To copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO '/usr1/proj/bray/sql/a_list_co
```

Here is a sample of data suitable for copying into a table from `STDIN`:

```
AF      AFGHANISTAN
AL      ALBANIA
DZ      ALGERIA
ZM      ZAMBIA
ZW      ZIMBABWE
```

Note that the white space on each line is actually a tab character.

The following is the same data, output in binary format. The data is shown after filtering through the Unix utility `od -c`. The table has three columns; the first has type `char(2)`, the second has type `text`, and the third has type `integer`. All the rows have a null value in the third column.

```
0000000  P   G   C   O   P   Y  \n 377  \r  \n  \0  \0  \0  \0  \0  \0
0000020  \0  \0  \0  \0 003  \0  \0  \0 002  A   F  \0  \0  \0 013  A
0000040  F   G   H   A   N   I   S   T   A   N 377 377 377 377  \0 003
0000060  \0  \0  \0 002  A   L  \0  \0  \0 007  A   L   B   A   N   I
0000100  A 377 377 377 377  \0 003  \0  \0  \0 002  D   Z  \0  \0  \0
0000120 007  A   L   G   E   R   I   A 377 377 377 377  \0 003  \0  \0
0000140  \0 002  Z   M  \0  \0  \0 006  Z   A   M   B   I   A 377 377
0000160 377 377  \0 003  \0  \0  \0 002  Z   W  \0  \0  \0  \b  Z   I
0000200  M   B   A   B   W   E 377 377 377 377 377 377
```

## Compatibility

There is no `COPY` statement in the SQL standard.

The following syntax was used before PostgreSQL version 7.3 and is still supported:

```
COPY [ BINARY ] tablename [ WITH OIDS ]  
FROM { 'filename' | STDIN }  
[ [USING] DELIMITERS 'delimiter' ]  
[ WITH NULL AS 'null string' ]
```

```
COPY [ BINARY ] tablename [ WITH OIDS ]  
TO { 'filename' | STDOUT }  
[ [USING] DELIMITERS 'delimiter' ]  
[ WITH NULL AS 'null string' ]
```

# CREATE AGGREGATE

## Name

CREATE AGGREGATE — define a new aggregate function

## Synopsis

```
CREATE AGGREGATE name ( input_data_type [ , ... ] ) (
    SFUNC = sfunc,
    STYPE = state_data_type
    [ , FINALFUNC = ffunc ]
    [ , INITCOND = initial_condition ]
    [ , SORTOP = sort_operator ]
)
```

or the old syntax

```
CREATE AGGREGATE name (
    BASETYPE = base_type,
    SFUNC = sfunc,
    STYPE = state_data_type
    [ , FINALFUNC = ffunc ]
    [ , INITCOND = initial_condition ]
    [ , SORTOP = sort_operator ]
)
```

## Description

CREATE AGGREGATE defines a new aggregate function. Some basic and commonly-used aggregate functions are included with the distribution; they are documented in Section 9.18. If one defines new types or needs an aggregate function not already provided, then CREATE AGGREGATE can be used to provide the desired features.

If a schema name is given (for example, CREATE AGGREGATE myschema.myagg ...) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data type(s). Two aggregates in the same schema can have the same name if they operate on different input types. The name and input data type(s) of an aggregate must also be distinct from the name and input data type(s) of every ordinary function in the same schema.

An aggregate function is made from one or two ordinary functions: a state transition function *sfunc*, and an optional final calculation function *ffunc*. These are used as follows:

```
sfunc( internal-state, next-data-values ) ---> next-internal-state
ffunc( internal-state ) ---> aggregate-value
```

PostgreSQL creates a temporary variable of data type *stype* to hold the current internal state of the aggregate. At each input row, the aggregate argument value(s) are calculated and the state transition function is invoked with the current state value and the new argument value(s) to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate's return value. If there is no final function then the ending state value is returned as-is.

An aggregate function can provide an initial condition, that is, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out null.

If the state transition function is declared “strict”, then it cannot be called with null inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is null, then at the first row with all-nonnull input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all-nonnull input values. This is handy for implementing aggregates like `max`. Note that this behavior is only available when *state\_data\_type* is the same as the first *input\_data\_type*. When these types are different, you must supply a nonnull initial condition or use a nonstrict transition function.

If the state transition function is not strict, then it will be called unconditionally at each input row, and must deal with null inputs and null transition values for itself. This allows the aggregate author to have full control over the aggregate's handling of null values.

If the final function is declared “strict”, then it will not be called when the ending state value is null; instead a null result will be returned automatically. (Of course this is just the normal behavior of strict functions.) In any case the final function has the option of returning a null value. For example, the final function for `avg` returns null when it sees there were zero input rows.

Aggregates that behave like `MIN` or `MAX` can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a *sort operator*. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```
SELECT agg(col) FROM tab;
```

must be equivalent to:

```
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate ignores null inputs, and that it delivers a null result if and only if there were no non-null inputs. Ordinarily, a data type's `<` operator is the proper sort operator for `MIN`, and `>` is the proper sort operator for `MAX`. Note that the optimization will never actually take effect unless the specified operator is the “less than” or “greater than” strategy member of a B-tree index operator class.

## Parameters

*name*

The name (optionally schema-qualified) of the aggregate function to create.

*input\_data\_type*

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write `*` in place of the list of input data types. (An example of such an aggregate is `count (*)`.)

*base\_type*

In the old syntax for `CREATE AGGREGATE`, the input data type is specified by a `base_type` parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function, specify the `base_type` as `"ANY"` (not `*`).

*sfunc*

The name of the state transition function to be called for each input row. For an  $N$ -argument aggregate function, the *sfunc* must take  $N+1$  arguments, the first being of type *state\_data\_type* and the rest matching the declared input data type(s) of the aggregate. The function must return a value of type *state\_data\_type*. This function takes the current state value and the current input data value(s), and returns the next state value.

*state\_data\_type*

The data type for the aggregate's state value.

*ffunc*

The name of the final function called to compute the aggregate's result after all input rows have been traversed. The function must take a single argument of type *state\_data\_type*. The return data type of the aggregate is defined as the return type of this function. If *ffunc* is not specified, then the ending state value is used as the aggregate's result, and the return type is *state\_data\_type*.

*initial\_condition*

The initial setting for the state value. This must be a string constant in the form accepted for the data type *state\_data\_type*. If not specified, the state value starts out null.

*sort\_operator*

The associated sort operator for a `MIN`- or `MAX`-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument aggregate).

The parameters of `CREATE AGGREGATE` can be written in any order, not just the order illustrated above.

## Examples

See Section 34.10.

## Compatibility

`CREATE AGGREGATE` is a PostgreSQL language extension. The SQL standard does not provide for user-defined aggregate functions.

## **See Also**

*ALTER AGGREGATE, DROP AGGREGATE*

# CREATE CAST

## Name

CREATE CAST — define a new cast

## Synopsis

```
CREATE CAST (sourcetype AS targettype)  
    WITH FUNCTION funcname (argtypes)  
    [ AS ASSIGNMENT | AS IMPLICIT ]
```

```
CREATE CAST (sourcetype AS targettype)  
    WITHOUT FUNCTION  
    [ AS ASSIGNMENT | AS IMPLICIT ]
```

## Description

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types. For example:

```
SELECT CAST(42 AS float8);
```

converts the integer constant 42 to type `float8` by invoking a previously specified function, in this case `float8(int4)`. (If no suitable cast has been defined, the conversion fails.)

Two types can be *binary compatible*, which means that they can be converted into one another “for free” without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types `text` and `varchar` are binary compatible.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS typename)` or `x::typename` construct.

If the cast is marked `AS ASSIGNMENT` then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that `foo.f1` is a column of type `text`, then:

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type `integer` to type `text` is marked `AS ASSIGNMENT`, otherwise not. (We generally use the term *assignment cast* to describe this kind of cast.)

If the cast is marked `AS IMPLICIT` then it can be invoked implicitly in any context, whether assignment or internally in an expression. (We generally use the term *implicit cast* to describe this kind of cast.) For example, consider this query:

```
SELECT 2 + 4.0;
```

The parser initially marks the constants as being of type `integer` and `numeric` respectively. There is no `integer + numeric` operator in the system catalogs, but there is a `numeric + numeric` operator. The

query will therefore succeed if a cast from `integer` to `numeric` is available and is marked `AS IMPLICIT` — which in fact it is. The parser will apply the implicit cast and resolve the query as if it had been written

```
SELECT CAST ( 2 AS numeric ) + 4.0;
```

Now, the catalogs also provide a cast from `numeric` to `integer`. If that cast were marked `AS IMPLICIT` — which it is not — then the parser would be faced with choosing between the above interpretation and the alternative of casting the `numeric` constant to `integer` and applying the `integer + integer` operator. Lacking any knowledge of which choice to prefer, it would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed `numeric-and-integer` expression as `numeric`; there is no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause PostgreSQL to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invocable only for information-preserving transformations between types in the same general type category. For example, the cast from `int2` to `int4` can reasonably be implicit, but the cast from `float8` to `int4` should probably be assignment-only. Cross-type-category casts, such as `text` to `int4`, are best made explicit-only.

To be able to create a cast, you must own the source or the target data type. To create a binary-compatible cast, you must be superuser. (This restriction is made because an erroneous binary-compatible cast conversion can easily crash the server.)

## Parameters

*sourcetype*

The name of the source data type of the cast.

*targettype*

The name of the target data type of the cast.

*funcname(argtypes)*

The function used to perform the cast. The function name can be schema-qualified. If it is not, the function will be looked up in the schema search path. The function's result data type must match the target type of the cast. Its arguments are discussed below.

`WITHOUT FUNCTION`

Indicates that the source type and the target type are binary compatible, so no function is required to perform the cast.

`AS ASSIGNMENT`

Indicates that the cast can be invoked implicitly in assignment contexts.

`AS IMPLICIT`

Indicates that the cast can be invoked implicitly in any context.

Cast implementation functions can have one to three arguments. The first argument type must be identical to the cast's source type. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise. (Bizarrely, the SQL spec demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types so that this matters.)

Ordinarily a cast must have different source and target data types. However, it is allowed to declare a cast with identical source and target types if it has a cast implementation function with more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## Notes

Use *DROP CAST* to remove user-defined casts.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (`text`, `varchar`, and `char(n)`). PostgreSQL will automatically handle a cast to a string type by invoking the other type's output function, or conversely handle a cast from a string type by invoking the other type's input function. These automatically-provided casts are known as *I/O conversion casts*. I/O conversion casts to string types are treated as assignment casts, while I/O conversion casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an I/O conversion cast, but usually the only reason to do so is if you want the conversion to be more easily invocable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function; but that is sufficiently surprising that you should think twice about whether it's a good idea. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

Prior to PostgreSQL 7.3, every function that had the same name as a data type, returned that data type, and took one argument of a different type was automatically a cast function. This convention has been abandoned in face of the introduction of schemas and to be able to represent binary compatible casts in the system catalogs. The built-in cast functions still follow this naming scheme, but they have to be shown as casts in the system catalog `pg_cast` as well.

While not required, it is recommended that you continue to follow this old convention of naming cast implementation functions after the target data type. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`. This notation is in fact nothing more nor less than a call of the cast implementation function; it is not specially treated as a cast. If your conversion functions are not named to support this convention then you will have surprised users. Since PostgreSQL allows

overloading of the same function name with different argument types, there is no difficulty in having multiple conversion functions from different types that all use the target type's name.

**Note:** Actually the preceding paragraph is an oversimplification: there are two cases in which a function-call construct will be treated as a cast request without having matched it to an actual function. If a function call *name*(*x*) does not exactly match any existing function, but *name* is the name of a data type and `pg_cast` provides a binary-compatible cast to this type from the type of *x*, then the call will be construed as a binary-compatible cast. This exception is made so that binary-compatible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no `pg_cast` entry but the cast would be to or from a string type, the call will be construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

## Examples

To create a cast from type `bigint` to type `int4` using the function `int4(bigint)`:

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint);
```

(This cast is already predefined in the system.)

## Compatibility

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-compatible types or extra arguments to implementation functions. `AS IMPLICIT` is a PostgreSQL extension, too.

*CREATE FUNCTION*, *CREATE TYPE*, *DROP CAST*

# CREATE CONSTRAINT TRIGGER

## Name

CREATE CONSTRAINT TRIGGER — define a new constraint trigger

## Synopsis

```
CREATE CONSTRAINT TRIGGER name
    AFTER event [ OR ... ]
    ON table_name
    [ FROM referenced_table_name ]
    { NOT DEFERRABLE | [ DEFERRABLE ] { INITIALLY IMMEDIATE | INITIALLY DEFERRED } }
    FOR EACH ROW
    EXECUTE PROCEDURE funcname ( arguments )
```

## Description

CREATE CONSTRAINT TRIGGER creates a *constraint trigger*. This is the same as a regular trigger except that the timing of the trigger firing can be adjusted using *SET CONSTRAINTS*. Constraint triggers must be AFTER ROW triggers. They can be fired either at the end of the statement causing the triggering event, or at the end of the containing transaction; in the latter case they are said to be *deferred*. A pending deferred-trigger firing can also be forced to happen immediately by using SET CONSTRAINTS.

## Parameters

*name*

The name of the constraint trigger. This is also the name to use when modifying the trigger's behavior using SET CONSTRAINTS. The name cannot be schema-qualified — the trigger inherits the schema of its table.

*event*

One of INSERT, UPDATE, or DELETE; this specifies the event that will fire the trigger. Multiple events can be specified using OR.

*table\_name*

The (possibly schema-qualified) name of the table in which the triggering events occur.

*referenced\_table\_name*

The (possibly schema-qualified) name of another table referenced by the constraint. This option is used for foreign-key constraints and is not recommended for general use.

DEFERRABLE  
NOT DEFERRABLE  
INITIALLY IMMEDIATE  
INITIALLY DEFERRED

The default timing of the trigger. See the *CREATE TABLE* documentation for details of these constraint options.

*funcname*

The function to call when the trigger is fired. See *CREATE TRIGGER* for details.

*arguments*

Optional argument strings to pass to the trigger function. See *CREATE TRIGGER* for details.

## Compatibility

*CREATE CONSTRAINT TRIGGER* is a PostgreSQL extension of the SQL standard.

## See Also

*CREATE TRIGGER*, *DROP TRIGGER*, *SET CONSTRAINTS*

# CREATE CONVERSION

## Name

CREATE CONVERSION — define a new encoding conversion

## Synopsis

```
CREATE [ DEFAULT ] CONVERSION name
    FOR source_encoding TO dest_encoding FROM funcname
```

## Description

CREATE CONVERSION defines a new conversion between character set encodings. Also, conversions that are marked **DEFAULT** can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B *and* from encoding B to A, must be defined.

To be able to create a conversion, you must have **EXECUTE** privilege on the function and **CREATE** privilege on the destination schema.

## Parameters

**DEFAULT**

The **DEFAULT** clause indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

*name*

The name of the conversion. The conversion name can be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

*source\_encoding*

The source encoding name.

*dest\_encoding*

The destination encoding name.

*funcname*

The function used to perform the conversion. The function name can be schema-qualified. If it is not, the function will be looked up in the path.

The function must have the following signature:

```
conv_proc(
    integer, -- source encoding ID
    integer, -- destination encoding ID
    cstring, -- source string (null terminated C string)
```

## *CREATE CONVERSION*

```
        internal, -- destination (fill with a null terminated C string)
        integer   -- source string length
    ) RETURNS void;
```

## Notes

Use `DROP CONVERSION` to remove user-defined conversions.

The privileges required to create a conversion might be changed in a future release.

## Examples

To create a conversion from encoding UTF8 to LATIN1 using myfunc:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

## Compatibility

`CREATE CONVERSION` is a PostgreSQL extension. There is no `CREATE CONVERSION` statement in the SQL standard.

## See Also

*ALTER CONVERSION*, *CREATE FUNCTION*, *DROP CONVERSION*

# CREATE DATABASE

## Name

CREATE DATABASE — create a new database

## Synopsis

```
CREATE DATABASE name
    [ [ WITH ] [ OWNER [=] dbowner ]
      [ TEMPLATE [=] template ]
      [ ENCODING [=] encoding ]
      [ TABLESPACE [=] tablespace ]
      [ CONNECTION LIMIT [=] conlimit ] ]
```

## Description

CREATE DATABASE creates a new PostgreSQL database.

To create a database, you must be a superuser or have the special `CREATEDB` privilege. See *CREATE USER*.

Normally, the creator becomes the owner of the new database. Superusers can create databases owned by other users, by using the `OWNER` clause. They can even create databases owned by users with no special privileges. Non-superusers with `CREATEDB` privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database `template1`. A different template can be specified by writing `TEMPLATE name`. In particular, by writing `TEMPLATE template0`, you can create a virgin database containing only the standard objects predefined by your version of PostgreSQL. This is useful if you wish to avoid copying any installation-local objects that might have been added to `template1`.

## Parameters

*name*

The name of a database to create.

*dbowner*

The name of the database user who will own the new database, or `DEFAULT` to use the default (namely, the user executing the command).

*template*

The name of the template from which to create the new database, or `DEFAULT` to use the default template (`template1`).

*encoding*

Character set encoding to use in the new database. Specify a string constant (e.g., 'SQL\_ASCII'), or an integer encoding number, or `DEFAULT` to use the default encoding (namely, the encoding of the template database). The character sets supported by the PostgreSQL server are described in Section 22.2.1. See below for additional restrictions.

*tablespace*

The name of the tablespace that will be associated with the new database, or `DEFAULT` to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database. See *CREATE TABLESPACE* for more information.

*connlimit*

How many concurrent connections can be made to this database. -1 (the default) means no limit.

Optional parameters can be written in any order, not only the order illustrated above.

## Notes

`CREATE DATABASE` cannot be executed inside a transaction block.

Errors along the line of “could not initialize database directory” are most likely related to insufficient permissions on the data directory, a full disk, or other file system problems.

Use *DROP DATABASE* to remove a database.

The program *createdb* is a wrapper program around this command, provided for convenience.

Although it is possible to copy a database other than `template1` by specifying its name as the template, this is not (yet) intended as a general-purpose “COPY DATABASE” facility. The principal limitation is that no other sessions can be connected to the template database while it is being copied. `CREATE DATABASE` will fail if any other connection exists when it starts; otherwise, new connections to the template database are locked out until `CREATE DATABASE` completes. See Section 20.3 for more information.

Any character set encoding specified for the new database must be compatible with the server's `LC_CTYPE` locale setting. If `LC_CTYPE` is `C` (or equivalently `POSIX`), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly, and so the apparent freedom to specify an encoding is illusory if you didn't initialize the database cluster in `C` locale. `CREATE DATABASE` will allow superusers to specify `SQL_ASCII` encoding regardless of the locale setting, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The `CONNECTION LIMIT` option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the database, it is possible that both will fail. Also, the limit is not enforced against superusers.

## Examples

To create a new database:

```
CREATE DATABASE lusiadas;
```

To create a database `sales` owned by user `salesapp` with a default tablespace of `salesspace`:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database `music` which supports the ISO-8859-1 character set:

```
CREATE DATABASE music ENCODING 'LATIN1';
```

## Compatibility

There is no `CREATE DATABASE` statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

## See Also

*ALTER DATABASE, DROP DATABASE*

# CREATE DOMAIN

## Name

CREATE DOMAIN — define a new domain

## Synopsis

```
CREATE DOMAIN name [ AS ] data_type
    [ DEFAULT expression ]
    [ constraint [ ... ] ]

where constraint is:

[ CONSTRAINT constraint_name ]
{ NOT NULL | NULL | CHECK (expression) }
```

## Description

CREATE DOMAIN creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner.

If a schema name is given (for example, CREATE DOMAIN myschema.mydomain ...) then the domain is created in the specified schema. Otherwise it is created in the current schema. The domain name must be unique among the types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same CHECK constraint to verify the address syntax. Define a domain rather than setting up each table's constraint individually.

## Parameters

*name*

The name (optionally schema-qualified) of a domain to be created.

*data\_type*

The underlying data type of the domain. This can include array specifiers.

DEFAULT *expression*

The DEFAULT clause specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value.

The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

`CONSTRAINT constraint_name`

An optional name for a constraint. If not specified, the system generates a name.

`NOT NULL`

Values of this domain are not allowed to be null.

`NULL`

Values of this domain are allowed to be null. This is the default.

This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

`CHECK (expression)`

`CHECK` clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested.

Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than `VALUE`.

## Examples

This example creates the `us_postal_code` data type and then uses the type in a table definition. A regular expression test is used to verify that the value looks like a valid US postal code:

```
CREATE DOMAIN us_postal_code AS TEXT
CHECK (
    VALUE ~ '^\\d{5}$'
OR VALUE ~ '^\\d{5}-\\d{4}$'
);

CREATE TABLE us_snail_addy (
    address_id SERIAL PRIMARY KEY,
    street1 TEXT NOT NULL,
    street2 TEXT,
    street3 TEXT,
    city TEXT NOT NULL,
    postal us_postal_code NOT NULL
);
```

## Compatibility

The command `CREATE DOMAIN` conforms to the SQL standard.

## **See Also**

*ALTER DOMAIN, DROP DOMAIN*

# CREATE FUNCTION

## Name

CREATE FUNCTION — define a new function

## Synopsis

```
CREATE [ OR REPLACE ] FUNCTION
    name ( [ [ argmode ] [ argname ] argtype [, ...] ] )
    [ RETURNS rettype ]
{ LANGUAGE langname
  | IMMUTABLE | STABLE | VOLATILE
  | CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
  | [ EXTERNAL ] SECURITY INVOKER | [ EXTERNAL ] SECURITY DEFINER
  | COST execution_cost
  | ROWS result_rows
  | SET configuration_parameter { TO value | = value | FROM CURRENT }
  | AS 'definition'
  | AS 'obj_file', 'link_symbol'
} ...
[ WITH ( attribute [, ...] ) ]
```

## Description

CREATE FUNCTION defines a new function. CREATE OR REPLACE FUNCTION will either create a new function, or replace an existing definition.

If a schema name is included, then the function is created in the specified schema. Otherwise it is created in the current schema. The name of the new function must not match any existing function with the same argument types in the same schema. However, functions of different argument types can share a name (this is called *overloading*).

To replace the current definition of an existing function, use CREATE OR REPLACE FUNCTION. It is not possible to change the name or argument types of a function this way (if you tried, you would actually be creating a new, distinct function). Also, CREATE OR REPLACE FUNCTION will not let you change the return type of an existing function. To do that, you must drop and recreate the function. (When using OUT parameters, that means you cannot change the names or types of any OUT parameters except by dropping the function.)

If you drop and then recreate a function, the new function is not the same entity as the old; you will have to drop existing rules, views, triggers, etc. that refer to the old function. Use CREATE OR REPLACE FUNCTION to change a function definition without breaking objects that refer to the function. Also, ALTER FUNCTION can be used to change most of the auxiliary properties of an existing function.

The user that creates the function becomes the owner of the function.

## Parameters

*name*

The name (optionally schema-qualified) of the function to create.

*argmode*

The mode of an argument: either `IN`, `OUT`, or `INOUT`. If omitted, the default is `IN`.

*argname*

The name of an argument. Some languages (currently only PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation. But the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types can be base, composite, or domain types, or can reference the type of a table column.

Depending on the implementation language it might also be allowed to specify “pseudotypes” such as `cstring`. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `tablename.columnname%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

*rettype*

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or can reference the type of a table column. Depending on the implementation language it might also be allowed to specify “pseudotypes” such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause can be omitted. If present, it must agree with the result type implied by the output parameters: `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `tablename.columnname%TYPE`.

*langname*

The name of the language that the function is implemented in. Can be `SQL`, `C`, `internal`, or the name of a user-defined procedural language. For backward compatibility, the name can be enclosed by single quotes.

`IMMUTABLE`

`STABLE`

`VOLATILE`

These attributes inform the query optimizer about the behavior of the function. At most one choice can be specified. If none of these appear, `VOLATILE` is the default assumption.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values; that is, it does not do database lookups or otherwise use

information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter variables (such as the current time zone), etc. Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

`VOLATILE` indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `curval()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

For additional details see Section 34.6.

`CALLED ON NULL INPUT`

`RETURNS NULL ON NULL INPUT`

`STRICT`

`CALLED ON NULL INPUT` (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately.

`RETURNS NULL ON NULL INPUT` or `STRICT` indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

`[EXTERNAL] SECURITY INVOKER`

`[EXTERNAL] SECURITY DEFINER`

`SECURITY INVOKER` indicates that the function is to be executed with the privileges of the user that calls it. That is the default. `SECURITY DEFINER` specifies that the function is to be executed with the privileges of the user that created it.

The key word `EXTERNAL` is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not only external ones.

*execution\_cost*

A positive number giving the estimated execution cost for the function, in units of `cpu_operator_cost`. If the function returns a set, this is the cost per returned row. If the cost is not specified, 1 unit is assumed for C-language and internal functions, and 100 units for functions in all other languages. Larger values cause the planner to try to avoid evaluating the function more often than necessary.

*result\_rows*

A positive number giving the estimated number of rows that the planner should expect the function to return. This is only allowed when the function is declared to return a set. The default assumption is 1000 rows.

*configuration\_parameter*  
*value*

The `SET` clause causes the specified configuration parameter to be set to the specified value when the function is entered, and then restored to its prior value when the function exits. `SET FROM CURRENT` saves the session's current value of the parameter as the value to be applied when the function is entered.

See *SET* and Chapter 18 for more information about allowed parameter names and values.

*definition*

A string constant defining the function; the meaning depends on the language. It can be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

*obj\_file*, *link\_symbol*

This form of the `AS` clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string *obj\_file* is the name of the file containing the dynamically loadable object, and *link\_symbol* is the function's link symbol, that is, the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined.

*attribute*

The historical way to specify optional pieces of information about the function. The following attributes can appear here:

`isStrict`

Equivalent to `STRICT` or `RETURNS NULL ON NULL INPUT`.

`isCachable`

`isCachable` is an obsolete equivalent of `IMMUTABLE`; it's still accepted for backwards-compatibility reasons.

Attribute names are not case-sensitive.

## Notes

Refer to Section 34.3 for further information on writing functions.

The full SQL type syntax is allowed for input arguments and return value. However, some details of the type specification (e.g., the precision field for type `numeric`) are the responsibility of the underlying function implementation and are silently swallowed (i.e., not recognized or enforced) by the `CREATE FUNCTION` command.

PostgreSQL allows function *overloading*; that is, the same name can be used for several different functions so long as they have distinct argument types. However, the C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

Two functions are considered the same if they have the same names and *input* argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
```

```
CREATE FUNCTION foo(int, out text) ...
```

When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once per session. To unload and reload the file (perhaps during development), use the *LOAD* command.

Use *DROP FUNCTION* to remove user-defined functions.

It is often helpful to use dollar quoting (see Section 4.1.2.2) to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them.

If a `SET` clause is attached to a function, then the effects of a `SET LOCAL` command executed inside the function for the same variable are restricted to the function: the configuration parameter's prior value is still restored at function exit. However, an ordinary `SET` command (without `LOCAL`) overrides the `SET` clause, much as it would do for a previous `SET LOCAL` command: the effects of such a command will persist after function exit, unless the current transaction is rolled back.

To be able to define a function, the user must have the `USAGE` privilege on the language.

## Examples

Here are some trivial examples to help you get started. For more information and examples, see Section 34.3.

```
CREATE FUNCTION add(integer, integer) RETURNS integer
    AS 'select $1 + $2;'
    LANGUAGE SQL
    IMMUTABLE
    RETURNS NULL ON NULL INPUT;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS integer AS $$
    BEGIN
        RETURN i + 1;
    END;
$$ LANGUAGE plpgsql;
```

Return a record containing multiple output parameters:

```
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```
CREATE TYPE dup_result AS (f1 int, f2 text);
```

```
CREATE FUNCTION dup(int) RETURNS dup_result
AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
LANGUAGE SQL;

SELECT * FROM dup(42);
```

## Writing SECURITY DEFINER Functions Safely

Because a SECURITY DEFINER function is executed with the privileges of the user that created it, care is needed to ensure that the function cannot be misused. For security, `search_path` should be set to exclude any schemas writable by untrusted users. This prevents malicious users from creating objects that mask objects used by the function. Particularly important in this regard is the temporary-table schema, which is searched first by default, and is normally writable by anyone. A secure arrangement can be had by forcing the temporary schema to be searched last. To do this, write `pg_temp` as the last entry in `search_path`. This function illustrates safe usage:

```
CREATE FUNCTION check_password(uname TEXT, pass TEXT)
RETURNS BOOLEAN AS $$
DECLARE passed BOOLEAN;
BEGIN
    SELECT (pwd = $2) INTO passed
    FROM   pwds
    WHERE  username = $1;

    RETURN passed;
END;
$$ LANGUAGE plpgsql
SECURITY DEFINER
-- Set a secure search_path: trusted schema(s), then 'pg_temp'.
SET search_path = admin, pg_temp;
```

Before PostgreSQL version 8.3, the `SET` option was not available, and so older functions may contain rather complicated logic to save, set, and restore `search_path`. The `SET` option is far easier to use for this purpose.

Another point to keep in mind is that by default, execute privilege is granted to `PUBLIC` for newly created functions (see *GRANT* for more information). Frequently you will wish to restrict use of a security definer function to only some users. To do that, you must revoke the default `PUBLIC` privileges and then grant execute privilege selectively. To avoid having a window where the new function is accessible to all, create it and set the privileges within a single transaction. For example:

```
BEGIN;
CREATE FUNCTION check_password(uname TEXT, pass TEXT) ... SECURITY DEFINER;
REVOKE ALL ON FUNCTION check_password(uname TEXT, pass TEXT) FROM PUBLIC;
GRANT EXECUTE ON FUNCTION check_password(uname TEXT, pass TEXT) TO admins;
COMMIT;
```

## Compatibility

A `CREATE FUNCTION` command is defined in SQL:1999 and later. The PostgreSQL version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, *argmode* can be written either before or after *argname*. But only the first way is standard-compliant.

# CREATE GROUP

## Name

CREATE GROUP — define a new database role

## Synopsis

```
CREATE GROUP name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| IN ROLE rolename [, ...]
| IN GROUP rolename [, ...]
| ROLE rolename [, ...]
| ADMIN rolename [, ...]
| USER rolename [, ...]
| SYSID uid
```

## Description

CREATE GROUP is now an alias for *CREATE ROLE*.

## Compatibility

There is no CREATE GROUP statement in the SQL standard.

## See Also

*CREATE ROLE*

# CREATE INDEX

## Name

CREATE INDEX — define a new index

## Synopsis

```
CREATE [ UNIQUE ] INDEX [ CONCURRENTLY ] name ON table [ USING method ]  
    ( { column | ( expression ) } [ opclass ] [ ASC | DESC ] [ NULLS { FIRST | LAST } ] [, ... ]  
    [ WITH ( storage_parameter = value [, ... ] ) ]  
    [ TABLESPACE tablespace ]  
    [ WHERE predicate ]
```

## Description

CREATE INDEX constructs an index *name* on the specified table. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

PostgreSQL provides the index methods B-tree, hash, GiST, and GIN. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a *partial index* is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used section, you can improve performance by creating an index on just that portion. Another possible application is to use `WHERE` with `UNIQUE` to enforce uniqueness over a subset of a table. See Section 11.8 for more discussion.

The expression used in the `WHERE` clause can refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Presently, subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be “immutable”, that is, their results must depend only on their arguments and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function immutable when you create it.

## Parameters

### UNIQUE

Causes the system to check for duplicate values in the table when the index is created (if data already exist) and each time data is added. Attempts to insert or update data which would result in duplicate entries will generate an error.

### CONCURRENTLY

When this option is used, PostgreSQL will build the index without taking any locks that prevent concurrent inserts, updates, or deletes on the table; whereas a standard index build locks out writes (but not reads) on the table until it's done. There are several caveats to be aware of when using this option — see *Building Indexes Concurrently*.

### *name*

The name of the index to be created. No schema name can be included here; the index is always created in the same schema as its parent table.

### *table*

The name (possibly schema-qualified) of the table to be indexed.

### *method*

The name of the index method to be used. Choices are `btree`, `hash`, `gist`, and `gin`. The default method is `btree`.

### *column*

The name of a column of the table.

### *expression*

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses can be omitted if the expression has the form of a function call.

### *opclass*

The name of an operator class. See below for details.

### ASC

Specifies ascending sort order (which is the default).

### DESC

Specifies descending sort order.

### NULLS FIRST

Specifies that nulls sort before non-nulls. This is the default when `DESC` is specified.

### NULLS LAST

Specifies that nulls sort after non-nulls. This is the default when `DESC` is not specified.

### *storage\_parameter*

The name of an index-method-specific storage parameter. See below for details.

*tablespace*

The tablespace in which to create the index. If not specified, `default_tablespace` is consulted, or `temp_tablespaces` for indexes on temporary tables.

*predicate*

The constraint expression for a partial index.

## Index Storage Parameters

The `WITH` clause can specify *storage parameters* for indexes. Each index method can have its own set of allowed storage parameters. The built-in index methods all accept a single parameter:

`FILLFACTOR`

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency. B-trees use a default fillfactor of 90, but any value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

## Building Indexes Concurrently

Creating an index can interfere with regular operation of a database. Normally PostgreSQL locks the table to be indexed against writes and performs the entire index build with a single scan of the table. Other transactions can still read the table, but if they try to insert, update, or delete rows in the table they will block until the index build is finished. This could have a severe effect if the system is a live production database. Very large tables can take many hours to be indexed, and even for smaller tables, an index build can lock out writers for periods that are unacceptably long for a production system.

PostgreSQL supports building indexes without locking out writes. This method is invoked by specifying the `CONCURRENTLY` option of `CREATE INDEX`. When this option is used, PostgreSQL must perform two scans of the table, and in addition it must wait for all existing transactions that could potentially use the index to terminate. Thus this method requires more total work than a standard index build and takes significantly longer to complete. However, since it allows normal operations to continue while the index is built, this method is useful for adding new indexes in a production environment. Of course, the extra CPU and I/O load imposed by the index creation might slow other operations.

In a concurrent index build, the index is actually entered into the system catalogs in one transaction, then the two table scans occur in a second and third transaction. If a problem arises while scanning the table, such as a uniqueness violation in a unique index, the `CREATE INDEX` command will fail but leave behind an “invalid” index. This index will be ignored for querying purposes because it might be incomplete; however it will still consume update overhead. The `psql \d` command will mark such an index as `INVALID`:

```
postgres=# \d tab
        Table "public.tab"
```

```

Column | Type   | Modifiers
-----+-----+-----
col    | integer |
Indexes:
    "idx" btree (col) INVALID

```

The recommended recovery method in such cases is to drop the index and try again to perform `CREATE INDEX CONCURRENTLY`. (Another possibility is to rebuild the index with `REINDEX`. However, since `REINDEX` does not support concurrent builds, this option is unlikely to seem attractive.)

Another caveat when building a unique index concurrently is that the uniqueness constraint is already being enforced against other transactions when the second table scan begins. This means that constraint violations could be reported in other queries prior to the index becoming available for use, or even in cases where the index build eventually fails. Also, if a failure does occur in the second scan, the “invalid” index continues to enforce its uniqueness constraint afterwards.

Concurrent builds of expression indexes and partial indexes are supported. Errors occurring in the evaluation of these expressions could cause behavior similar to that described above for unique constraint violations.

Regular index builds permit other regular index builds on the same table to occur in parallel, but only one concurrent index build can occur on a table at a time. In both cases, no other types of schema modification on the table are allowed meanwhile. Another difference is that a regular `CREATE INDEX` command can be performed within a transaction block, but `CREATE INDEX CONCURRENTLY` cannot.

## Notes

See Chapter 11 for information about when indexes can be used, when they are not used, and in which particular situations they can be useful.

Currently, only the B-tree and GiST index methods support multicolumn indexes. Up to 32 fields can be specified by default. (This limit can be altered when building PostgreSQL.) Only B-tree currently supports unique indexes.

An *operator class* can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column’s data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index. More information about operator classes is in Section 11.9 and in Section 34.14.

For index methods that support ordered scans (currently, only B-tree), the optional clauses `ASC`, `DESC`, `NULLS FIRST`, and/or `NULLS LAST` can be specified to reverse the normal sort direction of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column `DESC` index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as `SELECT ... ORDER BY x ASC, y DESC`. The `NULLS` options are useful if you

need to support “nulls sort low” behavior, rather than the default “nulls sort high”, in queries that depend on indexes to avoid sorting steps.

Use *DROP INDEX* to remove an index.

Prior releases of PostgreSQL also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If `USING rtree` is specified, `CREATE INDEX` will interpret it as `USING gist`, to simplify conversion of old databases to GiST.

## Examples

To create a B-tree index on the column `title` in the table `films`:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create an index on the expression `lower(title)`, allowing efficient case-insensitive searches:

```
CREATE INDEX lower_title_idx ON films ((lower(title)));
```

To create an index with non-default sort ordering of nulls:

```
CREATE INDEX title_idx_nulls_low ON films (title NULLS FIRST);
```

To create an index with non-default fill factor:

```
CREATE UNIQUE INDEX title_idx ON films (title) WITH (fillfactor = 70);
```

To create an index on the column `code` in the table `films` and have the index reside in the tablespace `indexspace`:

```
CREATE INDEX code_idx ON films(code) TABLESPACE indexspace;
```

To create an index without locking out writes to the table:

```
CREATE INDEX CONCURRENTLY sales_quantity_index ON sales_table (quantity);
```

## Compatibility

`CREATE INDEX` is a PostgreSQL language extension. There are no provisions for indexes in the SQL standard.

## **See Also**

*ALTER INDEX, DROP INDEX*

# CREATE LANGUAGE

## Name

`CREATE LANGUAGE` — define a new procedural language

## Synopsis

```
CREATE [ PROCEDURAL ] LANGUAGE name
CREATE [ TRUSTED ] [ PROCEDURAL ] LANGUAGE name
    HANDLER call_handler [ VALIDATOR valfunction ]
```

## Description

Using `CREATE LANGUAGE`, a PostgreSQL user can register a new procedural language with a PostgreSQL database. Subsequently, functions and trigger procedures can be defined in this new language.

`CREATE LANGUAGE` effectively associates the language name with a call handler that is responsible for executing functions written in the language. Refer to Chapter 37 for more information about language call handlers.

There are two forms of the `CREATE LANGUAGE` command. In the first form, the user supplies just the name of the desired language, and the PostgreSQL server consults the `pg_pltemplate` system catalog to determine the correct parameters. In the second form, the user supplies the language parameters along with the language name. The second form can be used to create a language that is not defined in `pg_pltemplate`, but this approach is considered obsolescent.

When the server finds an entry in the `pg_pltemplate` catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.

Ordinarily, the user must have the PostgreSQL superuser privilege to register a new language. However, the owner of a database can register a new language within that database if the language is listed in the `pg_pltemplate` catalog and is marked as allowed to be created by database owners (`tmpldbacreate` is true). The default is that trusted languages can be created by database owners, but this can be adjusted by superusers by modifying the contents of `pg_pltemplate`. The creator of a language becomes its owner and can later drop it, rename it, or assign it to a new owner.

## Parameters

`TRUSTED`

`TRUSTED` specifies that the call handler for the language is safe, that is, it does not offer an unprivileged user any functionality to bypass access restrictions. If this key word is omitted when registering the language, only users with the PostgreSQL superuser privilege can use this language to create new functions.

## PROCEDURAL

This is a noise word.

*name*

The name of the new procedural language. The language name is case insensitive. The name must be unique among the languages in the database.

For backward compatibility, the name can be enclosed by single quotes.

HANDLER *call\_handler*

*call\_handler* is the name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with PostgreSQL as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

VALIDATOR *valfunction*

*valfunction* is the name of a previously registered function that will be called when a new function in the language is created, to validate the new function. If no validator function is specified, then a new function will not be checked when it is created. The validator function must take one argument of type `oid`, which will be the OID of the to-be-created function, and will typically return `void`.

A validator function would typically inspect the function body for syntactical correctness, but it can also look at other properties of the function, for example if the language cannot handle certain argument types. To signal an error, the validator function should use the `ereport()` function. The return value of the function is ignored.

The `TRUSTED` option and the support function name(s) are ignored if the server has an entry for the specified language name in `pg_pltemplate`.

## Notes

The `createlang` program is a simple wrapper around the `CREATE LANGUAGE` command. It eases installation of procedural languages from the shell command line.

Use `DROP LANGUAGE`, or better yet the `droplang` program, to drop procedural languages.

The system catalog `pg_language` (see Section 44.21) records information about the currently installed languages. Also, `createlang` has an option to list the installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (i.e., everyone) for trusted languages. This can be revoked if desired.

Procedural languages are local to individual databases. However, a language can be installed into the `template1` database, which will cause it to be available automatically in all subsequently-created databases.

The call handler function and the validator function (if any) must already exist if the server does not have an entry for the language in `pg_pltemplate`. But when there is an entry, the functions need not already exist; they will be automatically defined if not present in the database. (This might result in `CREATE LANGUAGE` failing, if the shared library that implements the language is not available in the installation.)

In PostgreSQL versions before 7.3, it was necessary to declare handler functions as returning the placeholder type `opaque`, rather than `language_handler`. To support loading of old dump files, `CREATE LANGUAGE` will accept a function declared as returning `opaque`, but it will issue a notice and change the function's declared return type to `language_handler`.

## Examples

The preferred way of creating any of the standard procedural languages is just:

```
CREATE LANGUAGE plpgsql;
```

For a language not known in the `pg_pltemplate` catalog, a sequence such as this is needed:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
    AS '$libdir/plsample'
    LANGUAGE C;
CREATE LANGUAGE plsample
    HANDLER plsample_call_handler;
```

## Compatibility

`CREATE LANGUAGE` is a PostgreSQL extension.

## See Also

*ALTER LANGUAGE*, *CREATE FUNCTION*, *DROP LANGUAGE*, *GRANT*, *REVOKE*, *createlang*, *droplang*

# CREATE OPERATOR

## Name

CREATE OPERATOR — define a new operator

## Synopsis

```
CREATE OPERATOR name (  
    PROCEDURE = funcname  
    [, LEFTARG = lefttype ] [, RIGHTARG = righttype ]  
    [, COMMUTATOR = com_op ] [, NEGATOR = neg_op ]  
    [, RESTRICT = res_proc ] [, JOIN = join_proc ]  
    [, HASHES ] [, MERGES ]  
)
```

## Description

CREATE OPERATOR defines a new operator, *name*. The user who defines an operator becomes its owner. If a schema name is given then the operator is created in the specified schema. Otherwise it is created in the current schema.

The operator name is a sequence of up to NAMEDATALEN-1 (63 by default) characters from the following list:

+ - \* / < > = ~ ! @ # % ^ & | ' ?

There are a few restrictions on your choice of name:

- -- and /\* cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in + or –, unless the name also contains at least one of these characters:

~ ! @ # % ^ & | ' ?

For example, @- is an allowed operator name, but \*- is not. This restriction allows PostgreSQL to parse SQL-compliant commands without requiring spaces between tokens.

The operator != is mapped to <> on input, so these two names are always equivalent.

At least one of LEFTARG and RIGHTARG must be defined. For binary operators, both must be defined. For right unary operators, only LEFTARG should be defined, while for left unary operators only RIGHTARG should be defined.

The *funcname* procedure must have been previously defined using CREATE FUNCTION and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

The other clauses specify optional operator optimization clauses. Their meaning is detailed in Section 34.13.

## Parameters

*name*

The name of the operator to be defined. See above for allowable characters. The name can be schema-qualified, for example `CREATE OPERATOR myschema.+ ( . . . )`. If not, then the operator is created in the current schema. Two operators in the same schema can have the same name if they operate on different data types. This is called *overloading*.

*funcname*

The function used to implement this operator.

*lefttype*

The data type of the operator's left operand, if any. This option would be omitted for a left-unity operator.

*righttype*

The data type of the operator's right operand, if any. This option would be omitted for a right-unity operator.

*com\_op*

The commutator of this operator.

*neg\_op*

The negator of this operator.

*res\_proc*

The restriction selectivity estimator function for this operator.

*join\_proc*

The join selectivity estimator function for this operator.

HASHES

Indicates this operator can support a hash join.

MERGES

Indicates this operator can support a merge join.

To give a schema-qualified operator name in *com\_op* or the other optional arguments, use the `OPERATOR()` syntax, for example:

```
COMMUTATOR = OPERATOR(myschema.===) ,
```

## Notes

Refer to Section 34.12 for further information.

The obsolete options `SORT1`, `SORT2`, `LTCMP`, and `GTCMP` were formerly used to specify the names of sort operators associated with a merge-joinable operator. This is no longer necessary, since information about associated operators is found by looking at B-tree operator families instead. If one of these options is given, it is ignored except for implicitly setting `Merges` true.

Use *DROP OPERATOR* to delete user-defined operators from a database. Use *ALTER OPERATOR* to modify operators in a database.

## Examples

The following command defines a new operator, area-equality, for the data type `box`:

```
CREATE OPERATOR === (
    LEFTARG = box,
    RIGHTARG = box,
    PROCEDURE = area_equal_procedure,
    COMMUTATOR = ===,
    NEGATOR = !==,
    RESTRICT = area_restriction_procedure,
    JOIN = area_join_procedure,
    HASHES, MERGES
);
```

## Compatibility

`CREATE OPERATOR` is a PostgreSQL extension. There are no provisions for user-defined operators in the SQL standard.

## See Also

*ALTER OPERATOR*, *CREATE OPERATOR CLASS*, *DROP OPERATOR*

# CREATE OPERATOR CLASS

## Name

CREATE OPERATOR CLASS — define a new operator class

## Synopsis

```
CREATE OPERATOR CLASS name [ DEFAULT ] FOR TYPE data_type
  USING index_method [ FAMILY family_name ] AS
  { OPERATOR strategy_number operator_name [ ( op_type, op_type ) ] [ RECHECK ]
    | FUNCTION support_number [ ( op_type [ , op_type ] ) ] funcname ( argument_type [ , ... ] )
    | STORAGE storage_type
  } [ , ... ]
```

## Description

CREATE OPERATOR CLASS creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or “strategies” for this data type and this index method. The operator class also specifies the support procedures to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class can be created.

If a schema name is given then the operator class is created in the specified schema. Otherwise it is created in the current schema. Two operator classes in the same schema can have the same name only if they are for different index methods.

The user who defines an operator class becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator class definition could confuse or even crash the server.)

CREATE OPERATOR CLASS does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user’s responsibility to define a valid operator class.

Related operator classes can be grouped into *operator families*. To add a new operator class to an existing family, specify the FAMILY option in CREATE OPERATOR CLASS. Without this option, the new class is placed into a family named the same as the new class (creating that family if it doesn’t already exist).

Refer to Section 34.14 for further information.

## Parameters

*name*

The name of the operator class to be created. The name can be schema-qualified.

## DEFAULT

If present, the operator class will become the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

*data\_type*

The column data type that this operator class is for.

*index\_method*

The name of the index method this operator class is for.

*family\_name*

The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

*strategy\_number*

The index method's strategy number for an operator associated with the operator class.

*operator\_name*

The name (optionally schema-qualified) of an operator associated with the operator class.

*op\_type*

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a `FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree and hash indexes) or the class's data type (for GIN and GiST indexes). These defaults are always correct, so there is no point in specifying *op\_type* in a `FUNCTION` clause in `CREATE OPERATOR CLASS`, but the option is provided for consistency with the comparable syntax in `ALTER OPERATOR FAMILY`.

## RECHECK

If present, the index is "lossy" for this operator, and so the rows retrieved using the index must be rechecked to verify that they actually satisfy the qualification clause involving this operator.

*support\_number*

The index method's support procedure number for a function associated with the operator class.

*funcname*

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator class.

*argument\_types*

The parameter data type(s) of the function.

*storage\_type*

The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GIN and GiST) allow it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used.

The `OPERATOR`, `FUNCTION`, and `STORAGE` clauses can appear in any order.

## Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

## Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`). See `contrib/intarray/` for the complete example.

```
CREATE OPERATOR CLASS gist__int_ops
    DEFAULT FOR TYPE _int4 USING gist AS
        OPERATOR          3          &&,
        OPERATOR          6          =          RECHECK,
        OPERATOR          7          @>,
        OPERATOR          8          <@,
        OPERATOR          20         @@ (_int4, query_int),
        FUNCTION           1          g_int_consistent (internal, _int4, int4),
        FUNCTION           2          g_int_union (bytea, internal),
        FUNCTION           3          g_int_compress (internal),
        FUNCTION           4          g_int_decompress (internal),
        FUNCTION           5          g_int_penalty (internal, internal, internal),
        FUNCTION           6          g_int_picksplit (internal, internal),
        FUNCTION           7          g_int_same (_int4, _int4, internal);
```

## Compatibility

`CREATE OPERATOR CLASS` is a PostgreSQL extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

## See Also

*ALTER OPERATOR CLASS, DROP OPERATOR CLASS, CREATE OPERATOR FAMILY, ALTER OPERATOR FAMILY*

# CREATE OPERATOR FAMILY

## Name

CREATE OPERATOR FAMILY — define a new operator family

## Synopsis

```
CREATE OPERATOR FAMILY name USING index_method
```

## Description

CREATE OPERATOR FAMILY creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being “loose” in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent CREATE OPERATOR CLASS commands to add contained operator classes, and optionally ALTER OPERATOR FAMILY commands to add “loose” operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

Refer to Section 34.14 for further information.

## Parameters

*name*

The name of the operator family to be created. The name can be schema-qualified.

*index\_method*

The name of the index method this operator family is for.

## Compatibility

`CREATE OPERATOR FAMILY` is a PostgreSQL extension. There is no `CREATE OPERATOR FAMILY` statement in the SQL standard.

*ALTER OPERATOR FAMILY, DROP OPERATOR FAMILY, CREATE OPERATOR CLASS, ALTER OPERATOR CLASS, DROP OPERATOR CLASS*

# CREATE ROLE

## Name

CREATE ROLE — define a new database role

## Synopsis

```
CREATE ROLE name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| IN ROLE rolename [, ...]
| IN GROUP rolename [, ...]
| ROLE rolename [, ...]
| ADMIN rolename [, ...]
| USER rolename [, ...]
| SYSID uid
```

## Description

CREATE ROLE adds a new role to a PostgreSQL database cluster. A role is an entity that can own database objects and have database privileges; a role can be considered a “user”, a “group”, or both depending on how it is used. Refer to Chapter 19 and Chapter 21 for information about managing users and authentication. You must have CREATEROLE privilege or be a database superuser to use this command.

Note that roles are defined at the database cluster level, and so are valid in all databases in the cluster.

## Parameters

*name*

The name of the new role.

SUPERUSER  
NOSUPERUSER

These clauses determine whether the new role is a “superuser”, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed.

You must yourself be a superuser to create a new superuser. If not specified, `NOSUPERUSER` is the default.

`CREATEDB`  
`NOCREATEDB`

These clauses define a role's ability to create databases. If `CREATEDB` is specified, the role being defined will be allowed to create new databases. Specifying `NOCREATEDB` will deny a role the ability to create databases. If not specified, `NOCREATEDB` is the default.

`CREATEROLE`  
`NOCREATEROLE`

These clauses determine whether a role will be permitted to create new roles (that is, execute `CREATE ROLE`). A role with `CREATEROLE` privilege can also alter and drop other roles. If not specified, `NOCREATEROLE` is the default.

`CREATEUSER`  
`NOCREATEUSER`

These clauses are an obsolete, but still accepted, spelling of `SUPERUSER` and `NOSUPERUSER`. Note that they are *not* equivalent to `CREATEROLE` as one might naively expect!

`INHERIT`  
`NOINHERIT`

These clauses determine whether a role “inherits” the privileges of roles it is a member of. A role with the `INHERIT` attribute can automatically use whatever database privileges have been granted to all roles it is directly or indirectly a member of. Without `INHERIT`, membership in another role only grants the ability to `SET ROLE` to that other role; the privileges of the other role are only available after having done so. If not specified, `INHERIT` is the default.

`LOGIN`  
`NOLOGIN`

These clauses determine whether a role is allowed to log in; that is, whether the role can be given as the initial session authorization name during client connection. A role having the `LOGIN` attribute can be thought of as a user. Roles without this attribute are useful for managing database privileges, but are not users in the usual sense of the word. If not specified, `NOLOGIN` is the default, except when `CREATE ROLE` is invoked through its alternative spelling `CREATE USER`.

`CONNECTION LIMIT connlimit`

If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit.

`PASSWORD password`

Sets the role's password. (A password is only of use for roles having the `LOGIN` attribute, but you can nonetheless define one for roles without it.) If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`.

ENCRYPTED

UNENCRYPTED

These key words control whether the password is stored encrypted in the system catalogs. (If neither is specified, the default behavior is determined by the configuration parameter `password_encryption`.) If the presented password string is already in MD5-encrypted format, then it is stored encrypted as-is, regardless of whether `ENCRYPTED` or `UNENCRYPTED` is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore.

Note that older clients might lack support for the MD5 authentication mechanism that is needed to work with passwords that are stored encrypted.

VALID UNTIL '*timestamp*'

The `VALID UNTIL` clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will be valid for all time.

IN ROLE *rolename*

The `IN ROLE` clause lists one or more existing roles to which the new role will be immediately added as a new member. (Note that there is no option to add the new role as an administrator; use a separate `GRANT` command to do that.)

IN GROUP *rolename*

`IN GROUP` is an obsolete spelling of `IN ROLE`.

ROLE *rolename*

The `ROLE` clause lists one or more existing roles which are automatically added as members of the new role. (This in effect makes the new role a "group".)

ADMIN *rolename*

The `ADMIN` clause is like `ROLE`, but the named roles are added to the new role `WITH ADMIN OPTION`, giving them the right to grant membership in this role to others.

USER *rolename*

The `USER` clause is an obsolete spelling of the `ROLE` clause.

SYSID *uid*

The `SYSID` clause is ignored, but is accepted for backwards compatibility.

## Notes

Use `ALTER ROLE` to change the attributes of a role, and `DROP ROLE` to remove a role. All the attributes specified by `CREATE ROLE` can be modified by later `ALTER ROLE` commands.

The preferred way to add and remove members of roles that are being used as groups is to use `GRANT` and `REVOKE`.

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role *per se*. In particular, the expiration time is not enforced when logging in using a non-password-based authentication method.

The `INHERIT` attribute governs inheritance of grantable privileges (that is, access privileges for database objects and role memberships). It does not apply to the special role attributes set by `CREATE ROLE` and `ALTER ROLE`. For example, being a member of a role with `CREATEDB` privilege does not immediately grant the ability to create databases, even if `INHERIT` is set; it would be necessary to become that role via `SET ROLE` before creating a database.

The `INHERIT` attribute is the default for reasons of backwards compatibility: in prior releases of PostgreSQL, users always had access to all privileges of groups they were members of. However, `NOINHERIT` provides a closer match to the semantics specified in the SQL standard.

Be careful with the `CREATEROLE` privilege. There is no concept of inheritance for the privileges of a `CREATEROLE`-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if the role “user” has the `CREATEROLE` privilege but not the `CREATEDB` privilege, nonetheless it can create a new role with the `CREATEDB` privilege. Therefore, regard roles that have the `CREATEROLE` privilege as almost-superuser-roles.

PostgreSQL includes a program *createuser* that has the same functionality as `CREATE ROLE` (in fact, it calls this command) but can be run from the command shell.

The `CONNECTION LIMIT` option is only enforced approximately; if two new sessions start at about the same time when just one connection “slot” remains for the role, it is possible that both will fail. Also, the limit is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in cleartext, and it might also be logged in the client’s command history or the server log. The command *createuser*, however, transmits the password encrypted. Also, *psql* contains a command `\password` that can be used to safely change the password later.

## Examples

Create a role that can log in, but don’t give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role with a password:

```
CREATE USER davide WITH PASSWORD 'jw8s0F4';
```

(`CREATE USER` is the same as `CREATE ROLE` except that it implies `LOGIN`.)

Create a role with a password that is valid until the end of 2004. After one second has ticked in 2005, the password is no longer valid.

```
CREATE ROLE miriam WITH LOGIN PASSWORD 'jw8s0F4' VALID UNTIL '2005-01-01';
```

Create a role that can create databases and manage roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

## Compatibility

The `CREATE ROLE` statement is in the SQL standard, but the standard only requires the syntax

```
CREATE ROLE name [ WITH ADMIN rolename ]
```

Multiple initial administrators, and all the other options of `CREATE ROLE`, are PostgreSQL extensions.

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by each database implementation. In PostgreSQL we have chosen to unify users and roles into a single kind of entity. Roles therefore have many more optional attributes than they do in the standard.

The behavior specified by the SQL standard is most closely approximated by giving users the `NOINHERIT` attribute, while roles are given the `INHERIT` attribute.

*SET ROLE*, *ALTER ROLE*, *DROP ROLE*, *GRANT*, *REVOKE*, `createuser`

# CREATE RULE

## Name

CREATE RULE — define a new rewrite rule

## Synopsis

```
CREATE [ OR REPLACE ] RULE name AS ON event
    TO table [ WHERE condition ]
    DO [ ALSO | INSTEAD ] { NOTHING | command | ( command ; command ... ) }
```

## Description

CREATE RULE defines a new rule applying to a specified table or view. CREATE OR REPLACE RULE will either create a new rule, or replace an existing rule of the same name for the same table.

The PostgreSQL rule system allows one to define an alternative action to be performed on insertions, updates, or deletions in database tables. Roughly speaking, a rule causes additional commands to be executed when a given command on a given table is executed. Alternatively, an INSTEAD rule can replace a given command by another, or cause a command not to be executed at all. Rules are used to implement table views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the commands starts. If you actually want an operation that fires independently for each physical row, you probably want to use a trigger, not a rule. More information about the rules system is in Chapter 36.

Presently, ON SELECT rules must be unconditional INSTEAD rules and must have actions that consist of a single SELECT command. Thus, an ON SELECT rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's SELECT command rather than whatever had been stored in the table (if anything). It is considered better style to write a CREATE VIEW command than to create a real table and define an ON SELECT rule for it.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules (or any subset of those that's sufficient for your purposes) to replace update actions on the view with appropriate updates on other tables. If you want to support INSERT RETURNING and so on, then be sure to put a suitable RETURNING clause into each of these rules.

There is a catch if you try to use conditional rules for view updates: there *must* be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)

## Parameters

*name*

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

*event*

The event is one of `SELECT`, `INSERT`, `UPDATE`, or `DELETE`.

*table*

The name (optionally schema-qualified) of the table or view the rule applies to.

*condition*

Any SQL conditional expression (returning `boolean`). The condition expression cannot refer to any tables except `NEW` and `OLD`, and cannot contain aggregate functions.

`INSTEAD`

`INSTEAD` indicates that the commands should be executed *instead of* the original command.

`ALSO`

`ALSO` indicates that the commands should be executed *in addition to* the original command.

If neither `ALSO` nor `INSTEAD` is specified, `ALSO` is the default.

*command*

The command or commands that make up the rule action. Valid commands are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `NOTIFY`.

Within *condition* and *command*, the special table names `NEW` and `OLD` can be used to refer to values in the referenced table. `NEW` is valid in `ON INSERT` and `ON UPDATE` rules to refer to the new row being inserted or updated. `OLD` is valid in `ON UPDATE` and `ON DELETE` rules to refer to the existing row being updated or deleted.

## Notes

You must be the owner of a table to create or change rules for it.

In a rule for `INSERT`, `UPDATE`, or `DELETE` on a view, you can add a `RETURNING` clause that emits the view's columns. This clause will be used to compute the outputs if the rule is triggered by an `INSERT RETURNING`, `UPDATE RETURNING`, or `DELETE RETURNING` command respectively. When the rule is triggered by a command without `RETURNING`, the rule's `RETURNING` clause will be ignored. The current implementation allows only unconditional `INSTEAD` rules to contain `RETURNING`; furthermore there can be at most one `RETURNING` clause among all the rules for the same event. (This ensures that there is only one candidate `RETURNING` clause to be used to compute the results.) `RETURNING` queries on the view will be rejected if there is no `RETURNING` clause in any available rule.

It is very important to take care to avoid circular rules. For example, though each of the following two rule definitions are accepted by PostgreSQL, the `SELECT` command would cause PostgreSQL to report an error because of recursive expansion of a rule:

```

CREATE RULE "_RETURN" AS
  ON SELECT TO t1
  DO INSTEAD
    SELECT * FROM t2;

CREATE RULE "_RETURN" AS
  ON SELECT TO t2
  DO INSTEAD
    SELECT * FROM t1;

SELECT * FROM t1;

```

Presently, if a rule action contains a `NOTIFY` command, the `NOTIFY` command will be executed unconditionally, that is, the `NOTIFY` will be issued even if there are not any rows that the rule should apply to. For example, in:

```

CREATE RULE notify_me AS ON UPDATE TO mytable DO ALSO NOTIFY mytable;

UPDATE mytable SET name = 'foo' WHERE id = 42;

```

one `NOTIFY` event will be sent during the `UPDATE`, whether or not there are any rows that match the condition `id = 42`. This is an implementation restriction that might be fixed in future releases.

## Compatibility

`CREATE RULE` is a PostgreSQL language extension, as is the entire query rewrite system.

# CREATE SCHEMA

## Name

CREATE SCHEMA — define a new schema

## Synopsis

```
CREATE SCHEMA schemaname [ AUTHORIZATION username ] [ schema_element [ ... ] ]  
CREATE SCHEMA AUTHORIZATION username [ schema_element [ ... ] ]
```

## Description

CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names can duplicate those of other objects existing in other schemas. Named objects are accessed either by “qualifying” their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A CREATE command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema`).

Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the AUTHORIZATION clause is used, all the created objects will be owned by that user.

## Parameters

*schemaname*

The name of a schema to be created. If this is omitted, the user name is used as the schema name. The name cannot begin with `pg_`, as such names are reserved for system schemas.

*username*

The name of the user who will own the schema. If omitted, defaults to the user executing the command. Only superusers can create schemas owned by users other than themselves.

*schema\_element*

An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

## Notes

To create a schema, the invoking user must have the `CREATE` privilege for the current database. (Of course, superusers bypass this check.)

## Examples

Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for user `joe`; the schema will also be named `joe`:

```
CREATE SCHEMA AUTHORIZATION joe;
```

Create a schema and create a table and view within it:

```
CREATE SCHEMA hollywood
    CREATE TABLE films (title text, release date, awards text[])
    CREATE VIEW winners AS
        SELECT title, release FROM films WHERE awards IS NOT NULL;
```

Notice that the individual subcommands do not end with semicolons.

The following is an equivalent way of accomplishing the same result:

```
CREATE SCHEMA hollywood;
CREATE TABLE hollywood.films (title text, release date, awards text[]);
CREATE VIEW hollywood.winners AS
    SELECT title, release FROM hollywood.films WHERE awards IS NOT NULL;
```

## Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by PostgreSQL.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` can appear in any order. The present PostgreSQL implementation does not handle all cases of forward references in subcommands; it might sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. PostgreSQL allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on his schema to someone else.

## **See Also**

*ALTER SCHEMA, DROP SCHEMA*

# CREATE SEQUENCE

## Name

CREATE SEQUENCE — define a new sequence generator

## Synopsis

```
CREATE [ TEMPORARY | TEMP ] SEQUENCE name [ INCREMENT [ BY ] increment ]  
    [ MINVALUE minvalue | NO MINVALUE ] [ MAXVALUE maxvalue | NO MAXVALUE ]  
    [ START [ WITH ] start ] [ CACHE cache ] [ [ NO ] CYCLE ]  
    [ OWNED BY { table.column | NONE } ]
```

## Description

CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table with the name *name*. The generator will be owned by the user issuing the command.

If a schema name is given then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name cannot be given when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence, table, index, or view in the same schema.

After a sequence is created, you use the functions `nextval`, `currval`, and `setval` to operate on the sequence. These functions are documented in Section 9.15.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM name;
```

to examine the parameters and current state of a sequence. In particular, the `last_value` field of the sequence shows the last value allocated by any session. (Of course, this value might be obsolete by the time it's printed, if other sessions are actively doing `nextval` calls.)

## Parameters

TEMPORARY or TEMP

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

*name*

The name (optionally schema-qualified) of the sequence to be created.

*increment*

The optional clause `INCREMENT BY increment` specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

*minvalue*

`NO MINVALUE`

The optional clause `MINVALUE minvalue` determines the minimum value a sequence can generate. If this clause is not supplied or `NO MINVALUE` is specified, then defaults will be used. The defaults are 1 and  $-2^{63}-1$  for ascending and descending sequences, respectively.

*maxvalue*

`NO MAXVALUE`

The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If this clause is not supplied or `NO MAXVALUE` is specified, then default values will be used. The defaults are  $2^{63}-1$  and -1 for ascending and descending sequences, respectively.

*start*

The optional clause `START WITH start` allows the sequence to begin anywhere. The default starting value is *minvalue* for ascending sequences and *maxvalue* for descending ones.

*cache*

The optional clause `CACHE cache` specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache), and this is also the default.

`CYCLE`

`NO CYCLE`

The `CYCLE` option allows the sequence to wrap around when the *maxvalue* or *minvalue* has been reached by an ascending or descending sequence respectively. If the limit is reached, the next number generated will be the *minvalue* or *maxvalue*, respectively.

If `NO CYCLE` is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, `NO CYCLE` is the default.

`OWNED BY table.column`

`OWNED BY NONE`

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. `OWNED BY NONE`, the default, specifies that there is no such association.

## Notes

Use `DROP SEQUENCE` to remove a sequence.

Sequences are based on `bigint` arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807). On some older platforms, there might be no

compiler support for eight-byte integers, in which case sequences use regular `integer` arithmetic (range -2147483648 to +2147483647).

Unexpected results might be obtained if a `cache` setting greater than one is used for a sequence object that will be used concurrently by multiple sessions. Each session will allocate and cache successive sequence values during one access to the sequence object and increase the sequence object's `last_value` accordingly. Then, the next `cache-1` uses of `nextval` within that session simply return the preallocated values without touching the sequence object. So, any numbers allocated but not used within a session will be lost when that session ends, resulting in “holes” in the sequence.

Furthermore, although multiple sessions are guaranteed to allocate distinct sequence values, the values might be generated out of sequence when all the sessions are considered. For example, with a `cache` setting of 10, session A might reserve values 1..10 and return `nextval=1`, then session B might reserve values 11..20 and return `nextval=11` before session A has generated `nextval=2`. Thus, with a `cache` setting of one it is safe to assume that `nextval` values are generated sequentially; with a `cache` setting greater than one you should only assume that the `nextval` values are all distinct, not that they are generated purely sequentially. Also, `last_value` will reflect the latest value reserved by any session, whether or not it has yet been returned by `nextval`.

Another consideration is that a `setval` executed on such a sequence will not be noticed by other sessions until they have used up any preallocated values they have cached.

## Examples

Create an ascending sequence called `serial`, starting at 101:

```
CREATE SEQUENCE serial START 101;
```

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
-----
      101
```

Select the next number from this sequence:

```
SELECT nextval('serial');
```

```
nextval
-----
      102
```

Use this sequence in an `INSERT` command:

```
INSERT INTO distributors VALUES (nextval('serial'), 'nothing');
```

Update the sequence value after a `COPY FROM`:

```
BEGIN;  
COPY distributors FROM 'input_file';  
SELECT setval('serial', max(id)) FROM distributors;  
END;
```

## Compatibility

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- The standard's `AS <data type>` expression is not supported.
- Obtaining the next value is done using the `nextval()` function instead of the standard's `NEXT VALUE FOR` expression.
- The `OWNED BY` clause is a PostgreSQL extension.

[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

and *table\_constraint* is:

```
[ CONSTRAINT constraint_name ]
{ UNIQUE ( column_name [, ... ] ) index_parameters |
  PRIMARY KEY ( column_name [, ... ] ) index_parameters |
  CHECK ( expression ) |
  FOREIGN KEY ( column_name [, ... ] ) REFERENCES reftable [ ( refcolumn [, ... ] ) ]
  [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ] [ ON DELETE action ] [ ON UPDATE action ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

*index\_parameters* in UNIQUE and PRIMARY KEY constraints are:

```
[ WITH ( storage_parameter [= value] [, ... ] ) ]
[ USING INDEX TABLESPACE tablespace ]
```

## Description

`CREATE TABLE` will create a new, initially empty table in the current database. The table will be owned by the user issuing the command.

If a schema name is given (for example, `CREATE TABLE myschema.mytable ...`) then the table is created in the specified schema. Otherwise it is created in the current schema. Temporary tables exist in a special schema, so a schema name cannot be given when creating a temporary table. The name of the table must be distinct from the name of any other table, sequence, index, or view in the same schema.

`CREATE TABLE` also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify constraints (tests) that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

## Parameters

`TEMPORARY` or `TEMP`

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT` below). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

Optionally, `GLOBAL` or `LOCAL` can be written before `TEMPORARY` or `TEMP`. This makes no difference in PostgreSQL, but see *Compatibility*.

*table\_name*

The name (optionally schema-qualified) of the table to be created.

*column\_name*

The name of a column to be created in the new table.

*data\_type*

The data type of the column. This can include array specifiers. For more information on the data types supported by PostgreSQL, refer to Chapter 8.

`DEFAULT` *default\_expr*

The `DEFAULT` clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.

The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

```
INHERITS ( parent_table [, ... ] )
```

The optional `INHERITS` clause specifies a list of tables from which the new table automatically inherits all columns.

Use of `INHERITS` creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. However, inherited and new column declarations of the same name need not specify identical constraints: all constraints provided from any declaration are merged together and all are applied to the new table. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

```
LIKE parent_table [ { INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS |  
INDEXES } ]
```

The `LIKE` clause specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints.

Unlike `INHERITS`, the new table and original table are completely decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

Default expressions for the copied column definitions will only be copied if `INCLUDING DEFAULTS` is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having null defaults.

Not-null constraints are always copied to the new table. `CHECK` constraints will only be copied if `INCLUDING CONSTRAINTS` is specified; other types of constraints will never be copied. Also, no distinction is made between column constraints and table constraints — when constraints are requested, all check constraints are copied.

Any indexes on the original table will not be created on the new table, unless the `INCLUDING INDEXES` clause is specified.

Note also that unlike `INHERITS`, copied columns and constraints are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another `LIKE` clause, an error is signalled.

```
CONSTRAINT constraint_name
```

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like `col must be positive` can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

NOT NULL

The column is not allowed to contain null values.

NULL

The column is allowed to contain null values. This is the default.

This clause is only provided for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

UNIQUE (column constraint)

UNIQUE ( *column\_name* [, ... ] ) (table constraint)

The UNIQUE constraint specifies that a group of one or more columns of a table can contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns.

For the purpose of a unique constraint, null values are not considered equal.

Each unique table constraint must name a set of columns that is different from the set of columns named by any other unique or primary key constraint defined for the table. (Otherwise it would just be the same constraint listed twice.)

PRIMARY KEY (column constraint)

PRIMARY KEY ( *column\_name* [, ... ] ) (table constraint)

The primary key constraint specifies that a column or columns of a table can contain only unique (non-duplicate), nonnull values. Technically, PRIMARY KEY is merely a combination of UNIQUE and NOT NULL, but identifying a set of columns as primary key also provides metadata about the design of the schema, as a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

Only one primary key can be specified for a table, whether as a column constraint or a table constraint.

The primary key constraint should name a set of columns that is different from other sets of columns named by any unique constraint defined for the same table.

CHECK ( *expression* )

The CHECK clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. Should any row of an insert or update operation produce a FALSE result an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

Currently, CHECK expressions cannot contain subqueries nor refer to variables other than columns of the current row.

REFERENCES *reftable* [ ( *refcolumn* ) ] [ MATCH *matchtype* ] [ ON DELETE *action* ] [ ON UPDATE *action* ] (column constraint)

FOREIGN KEY ( *column* [, ... ] ) REFERENCES *reftable* [ ( *refcolumn* [, ... ] ) ] [ MATCH *matchtype* ] [ ON DELETE *action* ] [ ON UPDATE *action* ] (table constraint)

These clauses specify a foreign key constraint, which requires that a group of one or more columns of the new table must only contain values that match values in the referenced column(s) of some row of the referenced table. If *refcolumn* is omitted, the primary key of the *reftable* is used.

The referenced columns must be the columns of a unique or primary key constraint in the referenced table. Note that foreign key constraints cannot be defined between temporary tables and permanent tables.

A value inserted into the referencing column(s) is matched against the values of the referenced table and referenced columns using the given match type. There are three match types: `MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE`, which is also the default. `MATCH FULL` will not allow one column of a multicolumn foreign key to be null unless all foreign key columns are null. `MATCH SIMPLE` allows some foreign key columns to be null while other parts of the foreign key are not null. `MATCH PARTIAL` is not yet implemented.

In addition, when the data in the referenced columns is changed, certain actions are performed on the data in this table's columns. The `ON DELETE` clause specifies the action to perform when a referenced row in the referenced table is being deleted. Likewise, the `ON UPDATE` clause specifies the action to perform when a referenced column in the referenced table is being updated to a new value. If the row is updated, but the referenced column is not actually changed, no action is done. Referential actions other than the `NO ACTION` check cannot be deferred, even if the constraint is declared deferrable. There are the following possible actions for each clause:

#### `NO ACTION`

Produce an error indicating that the deletion or update would create a foreign key constraint violation. If the constraint is deferred, this error will be produced at constraint check time if there still exist any referencing rows. This is the default action.

#### `RESTRICT`

Produce an error indicating that the deletion or update would create a foreign key constraint violation. This is the same as `NO ACTION` except that the check is not deferrable.

#### `CASCADE`

Delete any rows referencing the deleted row, or update the value of the referencing column to the new value of the referenced column, respectively.

#### `SET NULL`

Set the referencing column(s) to null.

#### `SET DEFAULT`

Set the referencing column(s) to their default values.

If the referenced column(s) are changed frequently, it might be wise to add an index to the foreign key column so that referential actions associated with the foreign key column can be performed more efficiently.

#### `DEFERRABLE`

#### `NOT DEFERRABLE`

This controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the `SET CONSTRAINTS` command). `NOT DEFERRABLE` is the default. Only foreign key constraints currently accept this clause. All other constraint types are not deferrable.

INITIALLY IMMEDIATE

INITIALLY DEFERRED

If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is `INITIALLY IMMEDIATE`, it is checked after each statement. This is the default. If the constraint is `INITIALLY DEFERRED`, it is checked only at the end of the transaction. The constraint check time can be altered with the *SET CONSTRAINTS* command.

WITH ( *storage\_parameter* [= *value*] [, ... ] )

This clause specifies optional storage parameters for a table or index; see *Storage Parameters* for more information. The `WITH` clause for a table can also include `oids=true` (or just `oids`) to specify that rows of the new table should have OIDs (object identifiers) assigned to them, or `oids=false` to specify that the rows should not have OIDs. If `oids` is not specified, the default setting depends upon the `default_with_oids` configuration parameter. (If the new table inherits from any tables that have OIDs, then `oids=true` is forced even if the command says `oids=false`.)

If `oids=false` is specified or implied, the new table does not store OIDs and no OID will be assigned for a row inserted into it. This is generally considered worthwhile, since it will reduce OID consumption and thereby postpone the wraparound of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which makes them considerably less useful. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row (on most machines), slightly improving performance.

To remove OIDs from a table after it has been created, use *ALTER TABLE*.

WITH OIDS

WITHOUT OIDS

These are obsolescent syntaxes equivalent to `WITH (oids)` and `WITH (oids=false)`, respectively. If you wish to give both an `oids` setting and storage parameters, you must use the `WITH ( ... )` syntax; see above.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic *TRUNCATE* is done at each commit.

DROP

The temporary table will be dropped at the end of the current transaction block.

TABLESPACE *tablespace*

The *tablespace* is the name of the tablespace in which the new table is to be created. If not specified, `default_tablespace` is consulted, or `temp_tablespaces` if the table is temporary.

USING INDEX TABLESPACE *tablespace*

This clause allows selection of the tablespace in which the index associated with a `UNIQUE` or `PRIMARY KEY` constraint will be created. If not specified, `default_tablespace` is consulted, or `temp_tablespaces` if the table is temporary.

## Storage Parameters

The `WITH` clause can specify *storage parameters* for tables, and for indexes associated with a `UNIQUE` or `PRIMARY KEY` constraint. Storage parameters for indexes are documented in *CREATE INDEX*. The only storage parameter currently available for tables is:

`FILLFACTOR`

The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate.

## Notes

Using OIDs in new applications is not recommended: where possible, using a `SERIAL` or other sequence generator as the table's primary key is preferred. However, if your application does make use of OIDs to identify specific rows of a table, it is recommended to create a unique constraint on the `oid` column of that table, to ensure that OIDs in the table will indeed uniquely identify rows even after counter wraparound. Avoid assuming that OIDs are unique across tables; if you need a database-wide unique identifier, use the combination of `tableoid` and row OID for the purpose.

**Tip:** The use of `oids=false` is not recommended for tables with no primary key, since without either an OID or a unique data key, it is difficult to identify specific rows.

PostgreSQL automatically creates an index for each unique constraint and primary key constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. (See *CREATE INDEX* for more information.)

Unique constraints and primary keys are not inherited in the current implementation. This makes the combination of inheritance and unique constraints rather dysfunctional.

A table cannot have more than 1600 columns. (In practice, the effective limit is usually lower because of tuple-length constraints.)

## Examples

Create table `films` and table `distributors`:

```
CREATE TABLE films (
    code          char(5) CONSTRAINT firstkey PRIMARY KEY,
    title         varchar(40) NOT NULL,
    did           integer NOT NULL,
    date_prod     date,
    kind          varchar(10),
    len           interval hour to minute
);

CREATE TABLE distributors (
    did           integer PRIMARY KEY DEFAULT nextval('serial'),
    name          varchar(40) NOT NULL CHECK (name <> "")
);
```

Create a table with a 2-dimensional array:

```
CREATE TABLE array_int (
    vector        int[][]
);
```

Define a unique table constraint for the table `films`. Unique table constraints can be defined on one or more columns of the table:

```
CREATE TABLE films (
    code          char(5),
    title         varchar(40),
    did           integer,
    date_prod     date,
    kind          varchar(10),
    len           interval hour to minute,
    CONSTRAINT production UNIQUE(date_prod)
);
```

Define a check column constraint:

```
CREATE TABLE distributors (
    did           integer CHECK (did > 100),
    name          varchar(40)
);
```

Define a check table constraint:

```
CREATE TABLE distributors (
    did           integer,
```

```

        name      varchar(40)
        CONSTRAINT con1 CHECK (did > 100 AND name <> '')
    );

```

Define a primary key table constraint for the table `films`:

```

CREATE TABLE films (
    code      char(5),
    title     varchar(40),
    did       integer,
    date_prod date,
    kind      varchar(10),
    len       interval hour to minute,
    CONSTRAINT code_title PRIMARY KEY(code,title)
);

```

Define a primary key constraint for table `distributors`. The following two examples are equivalent, the first using the table constraint syntax, the second the column constraint syntax:

```

CREATE TABLE distributors (
    did       integer,
    name      varchar(40),
    PRIMARY KEY(did)
);

CREATE TABLE distributors (
    did       integer PRIMARY KEY,
    name      varchar(40)
);

```

Assign a literal constant default value for the column `name`, arrange for the default value of column `did` to be generated by selecting the next value of a sequence object, and make the default value of `modtime` be the time at which the row is inserted:

```

CREATE TABLE distributors (
    name      varchar(40) DEFAULT 'Luso Films',
    did       integer DEFAULT nextval('distributors_serial'),
    modtime   timestamp DEFAULT current_timestamp
);

```

Define two NOT NULL column constraints on the table `distributors`, one of which is explicitly given a name:

```

CREATE TABLE distributors (
    did       integer CONSTRAINT no_null NOT NULL,
    name      varchar(40) NOT NULL
);

```

Define a unique constraint for the `name` column:

```
CREATE TABLE distributors (
    did      integer,
    name     varchar(40) UNIQUE
);
```

The same, specified as a table constraint:

```
CREATE TABLE distributors (
    did      integer,
    name     varchar(40),
    UNIQUE(name)
);
```

Create the same table, specifying 70% fill factor for both the table and its unique index:

```
CREATE TABLE distributors (
    did      integer,
    name     varchar(40),
    UNIQUE(name) WITH (fillfactor=70)
)
WITH (fillfactor=70);
```

Create table `cinemas` in tablespace `diskvol1`:

```
CREATE TABLE cinemas (
    id serial,
    name text,
    location text
) TABLESPACE diskvol1;
```

## Compatibility

The `CREATE TABLE` command conforms to the SQL standard, with exceptions listed below.

### Temporary Tables

Although the syntax of `CREATE TEMPORARY TABLE` resembles that of the SQL standard, the effect is not the same. In the standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. PostgreSQL instead requires each session to issue its own `CREATE TEMPORARY TABLE` command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

The standard's definition of the behavior of temporary tables is widely ignored. PostgreSQL's behavior on this point is similar to that of several other SQL databases.

The standard's distinction between global and local temporary tables is not in PostgreSQL, since that distinction depends on the concept of modules, which PostgreSQL does not have. For compatibility's sake, PostgreSQL will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they have no effect.

The `ON COMMIT` clause for temporary tables also resembles the SQL standard, but has some differences. If the `ON COMMIT` clause is omitted, SQL specifies that the default behavior is `ON COMMIT DELETE ROWS`. However, the default behavior in PostgreSQL is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in SQL.

## Column Check Constraints

The SQL standard says that `CHECK` column constraints can only refer to the column they apply to; only `CHECK` table constraints can refer to multiple columns. PostgreSQL does not enforce this restriction; it treats column and table check constraints alike.

## NULL “Constraint”

The `NULL` “constraint” (actually a non-constraint) is a PostgreSQL extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is simply noise.

## Inheritance

Multiple inheritance via the `INHERITS` clause is a PostgreSQL language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by PostgreSQL.

## Zero-column tables

PostgreSQL allows a table of no columns to be created (for example, `CREATE TABLE foo();`). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for `ALTER TABLE DROP COLUMN`, so it seems cleaner to ignore this spec restriction.

## WITH clause

The `WITH` clause is a PostgreSQL extension; neither storage parameters nor OIDs are in the standard.

## **Tablespaces**

The PostgreSQL concept of tablespaces is not part of the standard. Hence, the clauses `TABLESPACE` and `USING INDEX TABLESPACE` are extensions.

## **See Also**

*ALTER TABLE, DROP TABLE, CREATE TABLESPACE*

# CREATE TABLE AS

## Name

CREATE TABLE AS — define a new table from the results of a query

## Synopsis

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } ] TABLE table_name
    [ (column_name [, ...] ) ]
    [ WITH ( storage_parameter [= value] [, ...] ) | WITH OIDS | WITHOUT OIDS ]
    [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
    [ TABLESPACE tablespace ]
    AS query
```

## Description

CREATE TABLE AS creates a table and fills it with data computed by a SELECT command. The table columns have the names and data types associated with the output columns of the SELECT (except that you can override the column names by giving an explicit list of new column names).

CREATE TABLE AS bears some resemblance to creating a view, but it is really quite different: it creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query. In contrast, a view re-evaluates its defining SELECT statement whenever it is queried.

## Parameters

GLOBAL or LOCAL

Ignored for compatibility. Refer to *CREATE TABLE* for details.

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to *CREATE TABLE* for details.

*table\_name*

The name (optionally schema-qualified) of the table to be created.

*column\_name*

The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query. If the table is created from an EXECUTE command, a column name list cannot be specified.

WITH ( *storage\_parameter* [= *value*] [, ... ] )

This clause specifies optional storage parameters for the new table; see *Storage Parameters* for more information. The WITH clause can also include OIDS=TRUE (or just OIDS) to specify that rows of the new table should have OIDs (object identifiers) assigned to them, or OIDS=FALSE to specify that the rows should not have OIDs. See *CREATE TABLE* for more information.

WITH OIDS

WITHOUT OIDS

These are obsolescent syntaxes equivalent to WITH (OIDS) and WITH (OIDS=FALSE), respectively. If you wish to give both an OIDS setting and storage parameters, you must use the WITH ( ... ) syntax; see above.

ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using ON COMMIT. The three options are:

PRESERVE ROWS

No special action is taken at the ends of transactions. This is the default behavior.

DELETE ROWS

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic *TRUNCATE* is done at each commit.

DROP

The temporary table will be dropped at the end of the current transaction block.

TABLESPACE *tablespace*

The *tablespace* is the name of the tablespace in which the new table is to be created. If not specified, *default\_tablespace* is consulted, or *temp\_tablespaces* if the table is temporary.

*query*

A *SELECT* or *VALUES* command, or an *EXECUTE* command that runs a prepared *SELECT* or *VALUES* query.

## Notes

This command is functionally similar to *SELECT INTO*, but it is preferred since it is less likely to be confused with other uses of the *SELECT INTO* syntax. Furthermore, *CREATE TABLE AS* offers a superset of the functionality offered by *SELECT INTO*.

Prior to PostgreSQL 8.0, *CREATE TABLE AS* always included OIDs in the table it created. As of PostgreSQL 8.0, the *CREATE TABLE AS* command allows the user to explicitly specify whether OIDs should be included. If the presence of OIDs is not explicitly specified, the *default\_with\_oids* configuration variable is used. As of PostgreSQL 8.1, this variable is false by default, so the default behavior is not identical to pre-8.0 releases. Applications that require OIDs in the table created by *CREATE TABLE AS* should explicitly specify WITH (OIDS) to ensure proper behavior.

## Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
CREATE TABLE films_recent AS
  SELECT * FROM films WHERE date_prod >= '2002-01-01';
```

Create a new temporary table `films_recent`, consisting of only recent entries from the table `films`, using a prepared statement. The new table has OIDs and will be dropped at commit:

```
PREPARE recentfilms(date) AS
  SELECT * FROM films WHERE date_prod > $1;
CREATE TEMP TABLE films_recent WITH (OIDS) ON COMMIT DROP AS
  EXECUTE recentfilms('2002-01-01');
```

## Compatibility

CREATE TABLE AS conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in PostgreSQL, these parentheses are optional.
- The standard defines a `WITH [ NO ] DATA` clause; this is not currently implemented by PostgreSQL. The behavior provided by PostgreSQL is equivalent to the standard's `WITH DATA` case. `WITH NO DATA` can be simulated by appending `LIMIT 0` to the query.
- PostgreSQL handles temporary tables in a way rather different from the standard; see *CREATE TABLE* for details.
- The `WITH` clause is a PostgreSQL extension; neither storage parameters nor OIDs are in the standard.
- The PostgreSQL concept of tablespaces is not part of the standard. Hence, the clause `TABLESPACE` is an extension.

# CREATE TABLESPACE

## Name

CREATE TABLESPACE — define a new tablespace

## Synopsis

```
CREATE TABLESPACE tablespacename [ OWNER username ] LOCATION 'directory'
```

## Description

CREATE TABLESPACE registers a new cluster-wide tablespace. The tablespace name must be distinct from the name of any existing tablespace in the database cluster.

A tablespace allows superusers to define an alternative location on the file system where the data files containing database objects (such as tables and indexes) can reside.

A user with appropriate privileges can pass *tablespacename* to CREATE DATABASE, CREATE TABLE, CREATE INDEX or ADD CONSTRAINT to have the data files for these objects stored within the specified tablespace.

## Parameters

*tablespacename*

The name of a tablespace to be created. The name cannot begin with `pg_`, as such names are reserved for system tablespaces.

*username*

The name of the user who will own the tablespace. If omitted, defaults to the user executing the command. Only superusers can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

*directory*

The directory that will be used for the tablespace. The directory must be empty and must be owned by the PostgreSQL system user. The directory must be specified by an absolute path name.

## Notes

Tablespaces are only supported on systems that support symbolic links.

CREATE TABLESPACE cannot be executed inside a transaction block.

## Examples

Create a tablespace dbspace at /data/dbs:

```
CREATE TABLESPACE dbspace LOCATION '/data/dbs';
```

Create a tablespace indexspace at /data/indexes owned by user genevieve:

```
CREATE TABLESPACE indexspace OWNER genevieve LOCATION '/data/indexes';
```

## Compatibility

CREATE TABLESPACE is a PostgreSQL extension.

## See Also

*CREATE DATABASE, CREATE TABLE, CREATE INDEX, DROP TABLESPACE, ALTER TABLESPACE*

# CREATE TEXT SEARCH CONFIGURATION

## Name

CREATE TEXT SEARCH CONFIGURATION — define a new text search configuration

## Synopsis

```
CREATE TEXT SEARCH CONFIGURATION name (  
    PARSER = parser_name |  
    COPY = source_config  
)
```

## Description

CREATE TEXT SEARCH CONFIGURATION creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent ALTER TEXT SEARCH CONFIGURATION commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.

If a schema name is given then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to Chapter 12 for further information.

## Parameters

*name*

The name of the text search configuration to be created. The name can be schema-qualified.

*parser\_name*

The name of the text search parser to use for this configuration.

*source\_config*

The name of an existing text search configuration to copy.

## **Notes**

The `PARSER` and `COPY` options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

## **Compatibility**

There is no `CREATE TEXT SEARCH CONFIGURATION` statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH CONFIGURATION, DROP TEXT SEARCH CONFIGURATION*

# CREATE TEXT SEARCH DICTIONARY

## Name

CREATE TEXT SEARCH DICTIONARY — define a new text search dictionary

## Synopsis

```
CREATE TEXT SEARCH DICTIONARY name (  
    TEMPLATE = template  
    [, option = value [, ... ]]  
)
```

## Description

CREATE TEXT SEARCH DICTIONARY creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to Chapter 12 for further information.

## Parameters

*name*

The name of the text search dictionary to be created. The name can be schema-qualified.

*template*

The name of the text search template that will define the basic behavior of this dictionary.

*option*

The name of a template-specific option to be set for this dictionary.

*value*

The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

## Examples

The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.

```
CREATE TEXT SEARCH DICTIONARY my_russian (  
    template = snowball,  
    language = russian,  
    stopwords = myrussian  
);
```

## Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

*ALTER TEXT SEARCH DICTIONARY*, *DROP TEXT SEARCH DICTIONARY*

# CREATE TEXT SEARCH PARSER

## Name

CREATE TEXT SEARCH PARSER — define a new text search parser

## Synopsis

```
CREATE TEXT SEARCH PARSER name (  
    START = start_function ,  
    GETTOKEN = gettoken_function ,  
    END = end_function ,  
    LEXTYPES = lextypes_function  
    [, HEADLINE = headline_function ]  
)
```

## Description

CREATE TEXT SEARCH PARSER creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH PARSER. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)

Refer to Chapter 12 for further information.

## Parameters

*name*

The name of the text search parser to be created. The name can be schema-qualified.

*start\_function*

The name of the start function for the parser.

*gettoken\_function*

The name of the get-next-token function for the parser.

*end\_function*

The name of the end function for the parser.

*lextypes\_function*

The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).

*headline\_function*

The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required.

The arguments can appear in any order, not only the one shown above.

## Compatibility

There is no `CREATE TEXT SEARCH PARSER` statement in the SQL standard.

## See Also

*ALTER TEXT SEARCH PARSER, DROP TEXT SEARCH PARSER*

# CREATE TEXT SEARCH TEMPLATE

## Name

CREATE TEXT SEARCH TEMPLATE — define a new text search template

## Synopsis

```
CREATE TEXT SEARCH TEMPLATE name (  
    [ INIT = init_function , ]  
    LEXIZE = lexize_function  
)
```

## Description

CREATE TEXT SEARCH TEMPLATE creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use CREATE TEXT SEARCH TEMPLATE. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the “unsafe” aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to Chapter 12 for further information.

## Parameters

*name*

The name of the text search template to be created. The name can be schema-qualified.

*init\_function*

The name of the init function for the template.

*lexize\_function*

The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the one shown above.

## **Compatibility**

There is no `CREATE TEXT SEARCH TEMPLATE` statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH TEMPLATE, DROP TEXT SEARCH TEMPLATE*

# CREATE TRIGGER

## Name

CREATE TRIGGER — define a new trigger

## Synopsis

```
CREATE TRIGGER name { BEFORE | AFTER } { event [ OR ... ] }  
  ON table [ FOR [ EACH ] { ROW | STATEMENT } ]  
  EXECUTE PROCEDURE funcname ( arguments )
```

## Description

CREATE TRIGGER creates a new trigger. The trigger will be associated with the specified table and will execute the specified function *funcname* when certain events occur.

The trigger can be specified to fire either before the operation is attempted on a row (before constraints are checked and the INSERT, UPDATE, or DELETE is attempted) or after the operation has completed (after constraints are checked and the INSERT, UPDATE, or DELETE has completed). If the trigger fires before the event, the trigger can skip the operation for the current row, or change the row being inserted (for INSERT and UPDATE operations only). If the trigger fires after the event, all changes, including the last insertion, update, or deletion, are “visible” to the trigger.

A trigger that is marked FOR EACH ROW is called once for every row that the operation modifies. For example, a DELETE that affects 10 rows will cause any ON DELETE triggers on the target relation to be called 10 separate times, once for each deleted row. In contrast, a trigger that is marked FOR EACH STATEMENT only executes once for any given operation, regardless of how many rows it modifies (in particular, an operation that modifies zero rows will still result in the execution of any applicable FOR EACH STATEMENT triggers).

If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.

SELECT does not modify any rows so you cannot create SELECT triggers. Rules and views are more appropriate in such cases.

Refer to Chapter 35 for more information about triggers.

## Parameters

*name*

The name to give the new trigger. This must be distinct from the name of any other trigger for the same table.

BEFORE

AFTER

Determines whether the function is called before or after the event.

*event*

One of INSERT, UPDATE, or DELETE; this specifies the event that will fire the trigger. Multiple events can be specified using OR.

*table*

The name (optionally schema-qualified) of the table the trigger is for.

FOR EACH ROW

FOR EACH STATEMENT

This specifies whether the trigger procedure should be fired once for every row affected by the trigger event, or just once per SQL statement. If neither is specified, FOR EACH STATEMENT is the default.

*funcname*

A user-supplied function that is declared as taking no arguments and returning type trigger, which is executed when the trigger fires.

*arguments*

An optional comma-separated list of arguments to be provided to the function when the trigger is executed. The arguments are literal string constants. Simple names and numeric constants can be written here, too, but they will all be converted to strings. Please check the description of the implementation language of the trigger function about how the trigger arguments are accessible within the function; it might be different from normal function arguments.

## Notes

To create a trigger on a table, the user must have the TRIGGER privilege on the table.

In PostgreSQL versions before 7.3, it was necessary to declare trigger functions as returning the placeholder type opaque, rather than trigger. To support loading of old dump files, CREATE TRIGGER will accept a function declared as returning opaque, but it will issue a notice and change the function's declared return type to trigger.

Use DROP TRIGGER to remove a trigger.

## Examples

Section 35.4 contains a complete example.

## Compatibility

The `CREATE TRIGGER` statement in PostgreSQL implements a subset of the SQL standard. The following functionality is currently missing:

- SQL allows triggers to fire on updates to specific columns (e.g., `AFTER UPDATE OF col1, col2`).
- SQL allows you to define aliases for the “old” and “new” rows or tables for use in the definition of the triggered action (e.g., `CREATE TRIGGER ... ON tablename REFERENCING OLD ROW AS somename NEW ROW AS othername ...`). Since PostgreSQL allows trigger procedures to be written in any number of user-defined languages, access to the data is handled in a language-specific way.
- PostgreSQL only allows the execution of a user-defined function for the triggered action. The standard allows the execution of a number of other SQL commands, such as `CREATE TABLE` as the triggered action. This limitation is not hard to work around by creating a user-defined function that executes the desired commands.

SQL specifies that multiple triggers should be fired in time-of-creation order. PostgreSQL uses name order, which was judged to be more convenient.

SQL specifies that `BEFORE DELETE` triggers on cascaded deletes fire *after* the cascaded `DELETE` completes. The PostgreSQL behavior is for `BEFORE DELETE` to always fire before the delete action, even a cascading one. This is considered more consistent. There is also unpredictable behavior when `BEFORE` triggers modify rows that are later to be modified by referential actions. This can lead to constraint violations or stored data that does not honor the referential constraint.

The ability to specify multiple actions for a single trigger using `OR` is a PostgreSQL extension of the SQL standard.

# CREATE TYPE

## Name

CREATE TYPE — define a new data type

## Synopsis

```
CREATE TYPE name AS
    ( attribute_name data_type [, ... ] )

CREATE TYPE name AS ENUM
    ( 'label' [, ... ] )

CREATE TYPE name (
    INPUT = input_function,
    OUTPUT = output_function
    [ , RECEIVE = receive_function ]
    [ , SEND = send_function ]
    [ , TYPMOD_IN = type_modifier_input_function ]
    [ , TYPMOD_OUT = type_modifier_output_function ]
    [ , ANALYZE = analyze_function ]
    [ , INTERNALLENGTH = { internallength | VARIABLE } ]
    [ , PASSEDBYVALUE ]
    [ , ALIGNMENT = alignment ]
    [ , STORAGE = storage ]
    [ , DEFAULT = default ]
    [ , ELEMENT = element ]
    [ , DELIMITER = delimiter ]
)

CREATE TYPE name
```

## Description

CREATE TYPE registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. (Because tables have associated data types, the type name must also be distinct from the name of any existing table in the same schema.)

## Composite Types

The first form of CREATE TYPE creates a composite type. The composite type is specified by a list of attribute names and data types. This is essentially the same as the row type of a table, but using CREATE

TYPE avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful as the argument or return type of a function.

## Enumerated Types

The second form of CREATE TYPE creates an enumerated (enum) type, as described in Section 8.7. Enum types take a list of one or more quoted labels, each of which must be less than NAMEDATALEN bytes long (64 in a standard PostgreSQL build).

## Base Types

The third form of CREATE TYPE creates a new base type (scalar type). The parameters can appear in any order, not only that illustrated above, and most are optional. You must register two or more functions (using CREATE FUNCTION) before defining the type. The support functions *input\_function* and *output\_function* are required, while the functions *receive\_function*, *send\_function*, *type\_modifier\_input\_function*, *type\_modifier\_output\_function* and *analyze\_function* are optional. Generally these functions have to be coded in C or another low-level language.

The *input\_function* converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. *output\_function* performs the reverse transformation. The input function can be declared as taking one argument of type *cstring*, or as taking three arguments of types *cstring*, *oid*, *integer*. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the *typmod* of the destination column, if known (-1 will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which might need to reject NULL inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type *cstring*. Output functions are not invoked for NULL values.

The optional *receive\_function* converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function can be declared as taking one argument of type *internal*, or as taking three arguments of types *internal*, *oid*, *integer*. The first argument is a pointer to a *StringInfo* buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared STRICT; if it is not, it will be called with a NULL first parameter when reading a NULL input value. The function must still return NULL in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which might need to reject NULL inputs.) Similarly, the optional *send\_function* converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type *bytea*. Send functions are not invoked for NULL values.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a *shell type*, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, `CREATE TYPE` with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

The optional `type_modifier_input_function` and `type_modifier_output_function` are needed if the type supports modifiers, that is optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. PostgreSQL allows user-defined types to take one or more simple constants or identifiers as modifiers; however, this information must be capable of being packed into a single non-negative integer value for storage in the system catalogs. The `type_modifier_input_function` is passed the declared modifier(s) in the form of a `cstring` array. It must check the values for validity (throwing an error if they are wrong), and if they are correct, return a single non-negative integer value that will be stored as the column “typmod”. Type modifiers will be rejected if the type does not have a `type_modifier_input_function`. The `type_modifier_output_function` converts the internal integer typmod value back to the correct form for user display. It must return a `cstring` value that is the exact string to append to the type name; for example `numeric`’s function might return `(30,2)`. It is allowed to omit the `type_modifier_output_function`, in which case the default display format is just the stored typmod value enclosed in parentheses.

The optional `analyze_function` performs type-specific statistics collection for columns of the data type. By default, `ANALYZE` will attempt to gather statistics using the type’s “equals” and “less-than” operators, if there is a default b-tree operator class for the type. For non-scalar types this behavior is likely to be unsuitable, so it can be overridden by specifying a custom analysis function. The analysis function must be declared to take a single argument of type `internal`, and return a `boolean` result. The detailed API for analysis functions appears in `src/include/commands/vacuum.h`.

While the details of the new type’s internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to PostgreSQL. Foremost of these is `internallength`. Base data types can be fixed-length, in which case `internallength` is a positive integer, or variable length, indicated by setting `internallength` to `VARIABLE`. (Internally, this is represented by setting `typelen` to -1.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. You cannot pass by value types whose internal representation is larger than the size of the `Datum` type (4 bytes on most machines, 8 bytes on a few).

The `alignment` parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The `storage` parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it’s still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages

moving the value out of the main table. (Data items with this storage strategy might still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

A default value can be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default can be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (`int4`), specify `ELEMENT = int4`. More details about array types appear below.

To indicate the delimiter to be used between values in the external representation of arrays of this type, *delimiter* can be set to a specific character. The default delimiter is the comma (`,`). Note that the delimiter is associated with the array element type, not the array type itself.

## Array Types

Whenever a user-defined type is created, PostgreSQL automatically creates an associated array type, whose name consists of the base type's name prepended with an underscore, and truncated if necessary to keep it less than `NAMEDATALEN` bytes long. (If the name so generated collides with an existing type name, the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`. The array type tracks any changes in its element type's owner or schema, and is dropped if the element type is.

You might reasonably ask why there is an `ELEMENT` option, if the system makes the correct array type automatically. The only case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type `point` is represented as just two floating-point numbers, which it allows to be accessed as `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by `array_in` and `array_out`. For historical reasons (i.e., this is clearly wrong but it's far too late to change it), subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

## Parameters

*name*

The name (optionally schema-qualified) of a type to be created.

*attribute\_name*

The name of an attribute (column) for the composite type.

*data\_type*

The name of an existing data type to become a column of the composite type.

*label*

A string literal representing the textual label associated with one value of an enum type.

*input\_function*

The name of a function that converts data from the type's external textual form to its internal form.

*output\_function*

The name of a function that converts data from the type's internal form to its external textual form.

*receive\_function*

The name of a function that converts data from the type's external binary form to its internal form.

*send\_function*

The name of a function that converts data from the type's internal form to its external binary form.

*type\_modifier\_input\_function*

The name of a function that converts numeric modifier(s) for the type into internal form.

*type\_modifier\_output\_function*

The name of a function that converts the internal form of the type's modifier(s) to external textual form.

*analyze\_function*

The name of a function that performs statistical analysis for the data type.

*internallength*

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

*alignment*

The storage alignment requirement of the data type. If specified, it must be `char`, `int2`, `int4`, or `double`; the default is `int4`.

*storage*

The storage strategy for the data type. If specified, must be `plain`, `external`, `extended`, or `main`; the default is `plain`.

*default*

The default value for the data type. If this is omitted, the default is null.

*element*

The type being created is an array; this specifies the type of the array elements.

*delimiter*

The delimiter character to be used between values in arrays made of this type.

## Notes

Because there are no restrictions on use of a data type once it's been created, creating a base type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require “secret” information to be used while converting it to or from external form.

Before PostgreSQL version 8.3, the name of a generated array type was always exactly the element type's name with one underscore character (`_`) prepended. (Type names were therefore restricted in length to one less character than other names.) While this is still usually the case, the array type name may vary from this in case of maximum-length names or collisions with user type names that begin with underscore. Writing code that depends on this convention is therefore deprecated. Instead, use `pg_type.typarray` to locate the array type associated with a given type.

It may be advisable to avoid using type and table names that begin with underscore. While the server will change generated array type names to avoid collisions with user-given names, there is still risk of confusion, particularly with old client software that may assume that type names beginning with underscores always represent arrays.

Before PostgreSQL version 8.2, the syntax `CREATE TYPE name` did not exist. The way to create a new base type was to create its input function first. In this approach, PostgreSQL will first see the name of the new data type as the return type of the input function. The shell type is implicitly created in this situation, and then it can be referenced in the definitions of the remaining I/O functions. This approach still works, but is deprecated and might be disallowed in some future release. Also, to avoid accidentally cluttering the catalogs with shell types as a result of simple typos in function definitions, a shell type will only be made this way when the input function is written in C.

In PostgreSQL versions before 7.3, it was customary to avoid creating a shell type at all, by replacing the functions' forward references to the type name with the placeholder pseudotype `opaque`. The `cstring` arguments and results also had to be declared as `opaque` before 7.3. To support loading of old dump files, `CREATE TYPE` will accept I/O functions declared using `opaque`, but it will issue a notice and change the function declarations to use the correct types.

## Examples

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT foid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates an enumerated type and uses it in a table definition:

```
CREATE TYPE bug_status AS ENUM ('new', 'open', 'closed');

CREATE TABLE bug (
    id serial,
```

```

        description text,
        status bug_status
    );

```

This example creates the base data type `box` and then uses the type in a table definition:

```

CREATE TYPE box;

CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS ... ;
CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS ... ;

CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function
);

CREATE TABLE myboxes (
    id integer,
    description box
);

```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```

CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function,
    ELEMENT = float4
);

```

which would allow a `box` value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```

CREATE TYPE bigobj (
    INPUT = lo_filein, OUTPUT = lo_fileout,
    INTERNALLENGTH = VARIABLE
);

CREATE TABLE big_objs (
    id integer,
    obj bigobj
);

```

More examples, including suitable input and output functions, are in Section 34.11.

## Compatibility

This `CREATE TYPE` command is a PostgreSQL extension. There is a `CREATE TYPE` statement in the SQL standard that is rather different in detail.

## See Also

*CREATE FUNCTION, DROP TYPE, ALTER TYPE, CREATE DOMAIN*

# CREATE USER

## Name

CREATE USER — define a new database role

## Synopsis

```
CREATE USER name [ [ WITH ] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| IN ROLE rolename [, ...]
| IN GROUP rolename [, ...]
| ROLE rolename [, ...]
| ADMIN rolename [, ...]
| USER rolename [, ...]
| SYSID uid
```

## Description

CREATE USER is now an alias for *CREATE ROLE*. The only difference is that when the command is spelled CREATE USER, LOGIN is assumed by default, whereas NOLOGIN is assumed when the command is spelled CREATE ROLE.

## Compatibility

The CREATE USER statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

## See Also

*CREATE ROLE*

# CREATE VIEW

## Name

CREATE VIEW — define a new view

## Synopsis

```
CREATE [ OR REPLACE ] [ TEMP | TEMPORARY ] VIEW name [ ( column_name [, ...] ) ]  
AS query
```

## Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. You can only replace a view with a new query that generates the identical set of columns (i.e., same column names and data types).

If a schema name is given (for example, CREATE VIEW myschema.myview ...) then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name cannot be given when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, or index in the same schema.

## Parameters

TEMPORARY or TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names.

If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

*name*

The name (optionally schema-qualified) of a view to be created.

*column\_name*

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

*query*

A SELECT or VALUES command which will provide the columns and rows of the view.

## Notes

Currently, views are read only: the system will not allow an insert, update, or delete on a view. You can get the effect of an updatable view by creating rules that rewrite inserts, etc. on the view into appropriate actions on other tables. For more information see *CREATE RULE*.

Use the *DROP VIEW* statement to drop views.

Be careful that the names and types of the view's columns will be assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form in two ways: the column name defaults to ?column?, and the column data type defaults to unknown. If you want a string literal in a view's result, use something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

Access to tables referenced in the view is determined by permissions of the view owner. However, functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call all functions used by the view.

## Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS
  SELECT *
  FROM films
  WHERE kind = 'Comedy';
```

## Compatibility

The SQL standard specifies some additional capabilities for the *CREATE VIEW* statement:

```
CREATE VIEW name [ ( column_name [, ...] ) ]
  AS query
  [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

The optional clauses for the full SQL command are:

CHECK OPTION

This option has to do with updatable views. All *INSERT* and *UPDATE* commands on the view will be checked to ensure data satisfy the view-defining condition (that is, the new data would be visible through the view). If they do not, the update will be rejected.

LOCAL

Check for integrity on this view.

CASCADED

Check for integrity on this view and on any dependent view. CASCADED is assumed if neither CASCADED nor LOCAL is specified.

CREATE OR REPLACE VIEW is a PostgreSQL language extension. So is the concept of a temporary view.

*ALTER VIEW, DROP VIEW*

# DEALLOCATE

## Name

DEALLOCATE — deallocate a prepared statement

## Synopsis

```
DEALLOCATE [ PREPARE ] { name | ALL }
```

## Description

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see *PREPARE*.

## Parameters

PREPARE

This key word is ignored.

*name*

The name of the prepared statement to deallocate.

ALL

Deallocate all prepared statements.

## Compatibility

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

## See Also

*EXECUTE*, *PREPARE*

# DECLARE

## Name

DECLARE — define a cursor

## Synopsis

```
DECLARE name [ BINARY ] [ INSENSITIVE ] [ [ NO ] SCROLL ]  
        CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

## Description

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. After the cursor is created, rows are fetched from it using *FETCH*.

## Parameters

*name*

The name of the cursor to be created.

BINARY

Causes the cursor to return data in binary rather than in text format.

INSENSITIVE

Indicates that data retrieved from the cursor should be unaffected by updates to the table(s) underlying the cursor that occur after the cursor is created. In PostgreSQL, this is the default behavior; so this key word has no effect and is only accepted for compatibility with the SQL standard.

SCROLL

NO SCROLL

SCROLL specifies that the cursor can be used to retrieve rows in a nonsequential fashion (e.g., backward). Depending upon the complexity of the query's execution plan, specifying SCROLL might impose a performance penalty on the query's execution time. NO SCROLL specifies that the cursor cannot be used to retrieve rows in a nonsequential fashion. The default is to allow scrolling in some cases; this is not the same as specifying SCROLL. See *Notes* for details.

WITH HOLD

WITHOUT HOLD

WITH HOLD specifies that the cursor can continue to be used after the transaction that created it successfully commits. WITHOUT HOLD specifies that the cursor cannot be used outside of the transaction that created it. If neither WITHOUT HOLD nor WITH HOLD is specified, WITHOUT HOLD is the default.

*query*

A *SELECT* or *VALUES* command which will provide the rows to be returned by the cursor.

The key words `BINARY`, `INSENSITIVE`, and `SCROLL` can appear in any order.

## Notes

Normal cursors return data in text format, the same as a *SELECT* would produce. The `BINARY` option specifies that the cursor should return data in binary format. This reduces conversion effort for both the server and client, at the cost of more programmer effort to deal with platform-dependent binary data formats. As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor, whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including `psql`, are not prepared to handle binary cursors and expect data to come back in the text format.

**Note:** When the client application uses the “extended query” protocol to issue a `FETCH` command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore PostgreSQL reports an error if such a command is used outside a transaction block. Use *BEGIN*, *COMMIT* and *ROLLBACK* to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

`WITH HOLD` may not be specified when the query includes `FOR UPDATE` or `FOR SHARE`.

The `SCROLL` option should be specified when defining a cursor that will be used to fetch backwards. This is required by the SQL standard. However, for compatibility with earlier versions, PostgreSQL will allow backward fetches without `SCROLL`, if the cursor’s query plan is simple enough that no extra overhead is needed to support it. However, application developers are advised not to rely on using backward fetches from a cursor that has not been created with `SCROLL`. If `NO SCROLL` is specified, then backward fetches are disallowed in any case.

If the cursor’s query includes `FOR UPDATE` or `FOR SHARE`, then returned rows are locked at the time they are first fetched, in the same way as for a regular *SELECT* command with these options. In addition, the returned rows will be the most up-to-date versions; therefore these options provide the equivalent of what the SQL standard calls a “sensitive cursor”. It is often wise to use `FOR UPDATE` if the cursor is intended to be used with `UPDATE ... WHERE CURRENT OF` or `DELETE ... WHERE CURRENT OF`, since this will prevent other sessions from changing the rows between the time they are fetched and the time they are

updated. Without `FOR UPDATE`, a subsequent `WHERE CURRENT OF` command will have no effect if the row was changed meanwhile.

`SCROLL` may not be specified when the query includes `FOR UPDATE` or `FOR SHARE`.

The SQL standard only makes provisions for cursors in embedded SQL. The PostgreSQL server does not implement an `OPEN` statement for cursors; a cursor is considered to be open when it is declared. However, ECPG, the embedded SQL preprocessor for PostgreSQL, supports the standard SQL cursor conventions, including those involving `DECLARE` and `OPEN` statements.

You can see all available cursors by querying the `pg_cursors` system view.

## Examples

To declare a cursor:

```
DECLARE liahona CURSOR FOR SELECT * FROM films;
```

See *FETCH* for more examples of cursor usage.

## Compatibility

The SQL standard says that it is implementation-dependent whether cursors are sensitive to concurrent updates of the underlying data by default. In PostgreSQL, cursors are insensitive by default, and can be made sensitive by specifying `FOR UPDATE`. Other products may work differently.

The SQL standard allows cursors only in embedded SQL and in modules. PostgreSQL permits cursors to be used interactively.

Binary cursors are a PostgreSQL extension.

*CLOSE*, *FETCH*, *MOVE*

# DELETE

## Name

DELETE — delete rows of a table

## Synopsis

```
DELETE FROM [ ONLY ] table [ [ AS ] alias ]  
    [ USING usinglist ]  
    [ WHERE condition | WHERE CURRENT OF cursor_name ]  
    [ RETURNING * | output_expression [ AS output_name ] [, ...] ]
```

## Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

**Tip:** *TRUNCATE* is a PostgreSQL extension that provides a faster mechanism to remove all rows from a table.

By default, DELETE will delete rows in the specified table and all its child tables. If you wish to delete only from the specific table mentioned, you must use the ONLY clause.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes DELETE to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in USING, can be computed. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the DELETE privilege on the table to delete from it, as well as the SELECT privilege for any table in the USING clause or whose values are read in the *condition*.

## Parameters

ONLY

If specified, delete rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

*table*

The name (optionally schema-qualified) of an existing table.

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `DELETE FROM foo AS f`, the remainder of the `DELETE` statement must refer to this table as `f` not `foo`.

*usinglist*

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition. This is similar to the list of tables that can be specified in the *FROM Clause* of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table in the *usinglist*, unless you wish to set up a self-join.

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be deleted.

*cursor\_name*

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a simple (non-join, non-aggregate) query on the `DELETE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition.

*output\_expression*

An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the *table* or table(s) listed in `USING`. Write `*` to return all columns.

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, a `DELETE` command returns a command tag of the form

```
DELETE count
```

The *count* is the number of rows deleted. If *count* is 0, no rows matched the *condition* (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

## Notes

PostgreSQL lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to delete all films produced by a given producer, one can do:

```
DELETE FROM films USING producers
```

```
WHERE producer_id = producers.id AND producers.name = 'foo';
```

What is essentially happening here is a join between `films` and `producers`, with all successfully joined `films` rows being marked for deletion. This syntax is not standard. A more standard way to do it is:

```
DELETE FROM films
  WHERE producer_id IN (SELECT id FROM producers WHERE name = 'foo');
```

In some cases the join style is easier to write or faster to execute than the sub-select style.

## Examples

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table `films`:

```
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```

Delete the row of `tasks` on which the cursor `c_tasks` is currently positioned:

```
DELETE FROM tasks WHERE CURRENT OF c_tasks;
```

## Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are PostgreSQL extensions.

# DISCARD

## Name

DISCARD — discard session state

## Synopsis

```
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

## Description

DISCARD releases internal resources associated with a database session. These resources are normally released at the end of the session.

DISCARD TEMP drops all temporary tables created in the current session. DISCARD PLANS releases all internally cached query plans. DISCARD ALL resets a session to its original state, discarding temporary resources and resetting session-local configuration changes.

## Parameters

TEMPORARY or TEMP

Drops all temporary tables created in the current session.

PLANS

Releases all cached query plans.

ALL

Releases all temporary resources associated with the current session and resets the session to its initial state. This has the same effect as executing the following sequence of statements:

```
SET SESSION AUTHORIZATION DEFAULT;  
RESET ALL;  
DEALLOCATE ALL;  
CLOSE ALL;  
UNLISTEN *;  
DISCARD PLANS;  
DISCARD TEMP;
```

## Notes

DISCARD ALL cannot be executed inside a transaction block.

## Compatibility

`DISCARD` is a PostgreSQL extension.

# DROP AGGREGATE

## Name

DROP AGGREGATE — remove an aggregate function

## Synopsis

```
DROP AGGREGATE [ IF EXISTS ] name ( type [ , ... ] ) [ CASCADE | RESTRICT ]
```

## Description

DROP AGGREGATE removes an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

## Parameters

IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing aggregate function.

*type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of input data types.

CASCADE

Automatically drop objects that depend on the aggregate function.

RESTRICT

Refuse to drop the aggregate function if any objects depend on it. This is the default.

## Examples

To remove the aggregate function `myavg` for type `integer`:

```
DROP AGGREGATE myavg(integer);
```

## **Compatibility**

There is no `DROP AGGREGATE` statement in the SQL standard.

## **See Also**

*ALTER AGGREGATE, CREATE AGGREGATE*

# DROP CAST

## Name

DROP CAST — remove a cast

## Synopsis

```
DROP CAST [ IF EXISTS ] (sourcetype AS targettype) [ CASCADE | RESTRICT ]
```

## Description

DROP CAST removes a previously defined cast.

To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

## Parameters

IF EXISTS

Do not throw an error if the cast does not exist. A notice is issued in this case.

*sourcetype*

The name of the source data type of the cast.

*targettype*

The name of the target data type of the cast.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on casts.

## Examples

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

## **Compatibility**

The `DROP CAST` command conforms to the SQL standard.

## **See Also**

*CREATE CAST*

# DROP CONVERSION

## Name

DROP CONVERSION — remove a conversion

## Synopsis

```
DROP CONVERSION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP CONVERSION removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

## Parameters

IF EXISTS

Do not throw an error if the conversion does not exist. A notice is issued in this case.

*name*

The name of the conversion. The conversion name can be schema-qualified.

CASCADE

RESTRICT

These key words do not have any effect, since there are no dependencies on conversions.

## Examples

To drop the conversion named `myname`:

```
DROP CONVERSION myname;
```

## Compatibility

There is no DROP CONVERSION statement in the SQL standard.

## **See Also**

*ALTER CONVERSION, CREATE CONVERSION*

# DROP DATABASE

## Name

`DROP DATABASE` — remove a database

## Synopsis

```
DROP DATABASE [ IF EXISTS ] name
```

## Description

`DROP DATABASE` drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. Also, it cannot be executed while you or anyone else are connected to the target database. (Connect to `postgres` or any other database to issue this command.)

`DROP DATABASE` cannot be undone. Use it with care!

## Parameters

`IF EXISTS`

Do not throw an error if the database does not exist. A notice is issued in this case.

*name*

The name of the database to remove.

## Notes

`DROP DATABASE` cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program *dropdb* instead, which is a wrapper around this command.

## Compatibility

There is no `DROP DATABASE` statement in the SQL standard.

## See Also

`CREATE DATABASE`

# DROP DOMAIN

## Name

`DROP DOMAIN` — remove a domain

## Synopsis

```
DROP DOMAIN [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP DOMAIN` removes a domain. Only the owner of a domain can remove it.

## Parameters

`IF EXISTS`

Do not throw an error if the domain does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing domain.

`CASCADE`

Automatically drop objects that depend on the domain (such as table columns).

`RESTRICT`

Refuse to drop the domain if any objects depend on it. This is the default.

## Examples

To remove the domain `box`:

```
DROP DOMAIN box;
```

## Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a PostgreSQL extension.

## **See Also**

*CREATE DOMAIN, ALTER DOMAIN*

# DROP FUNCTION

## Name

DROP FUNCTION — remove a function

## Synopsis

```
DROP FUNCTION [ IF EXISTS ] name ( [ argmode ] [ argname ] argtype [, ...] )  
[ CASCADE | RESTRICT ]
```

## Description

DROP FUNCTION removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions can exist with the same name and different argument lists.

## Parameters

IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing function.

*argmode*

The mode of an argument: either IN, OUT, or INOUT. If omitted, the default is IN. Note that DROP FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN and INOUT arguments.

*argname*

The name of an argument. Note that DROP FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any.

CASCADE

Automatically drop objects that depend on the function (such as operators or triggers).

RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.

## Examples

This command removes the square root function:

```
DROP FUNCTION sqrt(integer);
```

## Compatibility

A `DROP FUNCTION` statement is defined in the SQL standard, but it is not compatible with this command.

## See Also

*CREATE FUNCTION*, *ALTER FUNCTION*

# DROP GROUP

## Name

`DROP GROUP` — remove a database role

## Synopsis

```
DROP GROUP [ IF EXISTS ] name [, ...]
```

## Description

`DROP GROUP` is now an alias for *DROP ROLE*.

## Compatibility

There is no `DROP GROUP` statement in the SQL standard.

## See Also

*DROP ROLE*

# DROP INDEX

## Name

`DROP INDEX` — remove an index

## Synopsis

```
DROP INDEX [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP INDEX` drops an existing index from the database system. To execute this command you must be the owner of the index.

## Parameters

`IF EXISTS`

Do not throw an error if the index does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an index to remove.

`CASCADE`

Automatically drop objects that depend on the index.

`RESTRICT`

Refuse to drop the index if any objects depend on it. This is the default.

## Examples

This command will remove the index `title_idx`:

```
DROP INDEX title_idx;
```

## Compatibility

`DROP INDEX` is a PostgreSQL language extension. There are no provisions for indexes in the SQL standard.

## **See Also**

*CREATE INDEX*

# DROP LANGUAGE

## Name

`DROP LANGUAGE` — remove a procedural language

## Synopsis

```
DROP [ PROCEDURAL ] LANGUAGE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

`DROP LANGUAGE` removes the definition of a previously registered procedural language. You must be a superuser or the owner of the language to use `DROP LANGUAGE`.

## Parameters

`IF EXISTS`

Do not throw an error if the language does not exist. A notice is issued in this case.

*name*

The name of an existing procedural language. For backward compatibility, the name can be enclosed by single quotes.

`CASCADE`

Automatically drop objects that depend on the language (such as functions in the language).

`RESTRICT`

Refuse to drop the language if any objects depend on it. This is the default.

## Examples

This command removes the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

## Compatibility

There is no `DROP LANGUAGE` statement in the SQL standard.

## **See Also**

*ALTER LANGUAGE*, *CREATE LANGUAGE*, droplang

# DROP OPERATOR

## Name

DROP OPERATOR — remove an operator

## Synopsis

```
DROP OPERATOR [ IF EXISTS ] name ( { lefttype | NONE } , { righttype | NONE } ) [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

## Parameters

IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator.

*lefttype*

The data type of the operator's left operand; write NONE if the operator has no left operand.

*righttype*

The data type of the operator's right operand; write NONE if the operator has no right operand.

CASCADE

Automatically drop objects that depend on the operator.

RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

## Examples

Remove the power operator  $a^b$  for type integer:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator  $\sim b$  for type bit:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator `x!` for type `bigint`:

```
DROP OPERATOR ! (bigint, none);
```

## Compatibility

There is no `DROP OPERATOR` statement in the SQL standard.

## See Also

*CREATE OPERATOR*, *ALTER OPERATOR*

# DROP OPERATOR CLASS

## Name

DROP OPERATOR CLASS — remove an operator class

## Synopsis

```
DROP OPERATOR CLASS [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR CLASS drops an existing operator class. To execute this command you must be the owner of the operator class.

DROP OPERATOR CLASS does not drop any of the operators or functions referenced by the class. If there are any indexes depending on the operator class, you will need to specify CASCADE for the drop to complete.

## Parameters

IF EXISTS

Do not throw an error if the operator class does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator class.

*index\_method*

The name of the index access method the operator class is for.

CASCADE

Automatically drop objects that depend on the operator class.

RESTRICT

Refuse to drop the operator class if any objects depend on it. This is the default.

## Notes

DROP OPERATOR CLASS will not drop the operator family containing the class, even if there is nothing else left in the family (in particular, in the case where the family was implicitly created by CREATE OPERATOR CLASS). An empty operator family is harmless, but for the sake of tidiness you might wish to remove the family with DROP OPERATOR FAMILY; or perhaps better, use DROP OPERATOR FAMILY in the first place.

## Examples

Remove the B-tree operator class `widget_ops`:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add `CASCADE` to drop such indexes along with the operator class.

## Compatibility

There is no `DROP OPERATOR CLASS` statement in the SQL standard.

## See Also

*ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR FAMILY*

# DROP OPERATOR FAMILY

## Name

DROP OPERATOR FAMILY — remove an operator family

## Synopsis

```
DROP OPERATOR FAMILY [ IF EXISTS ] name USING index_method [ CASCADE | RESTRICT ]
```

## Description

DROP OPERATOR FAMILY drops an existing operator family. To execute this command you must be the owner of the operator family.

DROP OPERATOR FAMILY includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify CASCADE for the drop to complete.

## Parameters

IF EXISTS

Do not throw an error if the operator family does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing operator family.

*index\_method*

The name of the index access method the operator family is for.

CASCADE

Automatically drop objects that depend on the operator family.

RESTRICT

Refuse to drop the operator family if any objects depend on it. This is the default.

## Examples

Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use operator classes within the family. Add CASCADE to drop such indexes along with the operator family.

## **Compatibility**

There is no `DROP OPERATOR FAMILY` statement in the SQL standard.

## **See Also**

*ALTER OPERATOR FAMILY, CREATE OPERATOR FAMILY, ALTER OPERATOR CLASS, CREATE OPERATOR CLASS, DROP OPERATOR CLASS*

# DROP OWNED

## Name

`DROP OWNED` — remove database objects owned by a database role

## Synopsis

```
DROP OWNED BY name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP OWNED` drops all the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database will also be revoked.

## Parameters

*name*

The name of a role whose objects will be dropped, and whose privileges will be revoked.

`CASCADE`

Automatically drop objects that depend on the affected objects.

`RESTRICT`

Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

## Notes

`DROP OWNED` is often used to prepare for the removal of one or more roles. Because `DROP OWNED` only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the `CASCADE` option might make the command recurse to objects owned by other users.

The `REASSIGN OWNED` command is an alternative that reassigns the ownership of all the database objects owned by one or more roles.

## Compatibility

The `DROP OWNED` statement is a PostgreSQL extension.

## **See Also**

*REASSIGN OWNED, DROP ROLE*

# DROP ROLE

## Name

`DROP ROLE` — remove a database role

## Synopsis

```
DROP ROLE [ IF EXISTS ] name [, ...]
```

## Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself; to drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database of the cluster; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted. The *REASSIGN OWNED* and *DROP OWNED* commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

## Parameters

`IF EXISTS`

Do not throw an error if the role does not exist. A notice is issued in this case.

*name*

The name of the role to remove.

## Notes

PostgreSQL includes a program *dropuser* that has the same functionality as this command (in fact, it calls this command) but can be run from the command shell.

## Examples

To drop a role:

```
DROP ROLE jonathan;
```

## **Compatibility**

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than PostgreSQL uses.

## **See Also**

*CREATE ROLE, ALTER ROLE, SET ROLE*

# DROP RULE

## Name

`DROP RULE` — remove a rewrite rule

## Synopsis

```
DROP RULE [ IF EXISTS ] name ON relation [ CASCADE | RESTRICT ]
```

## Description

`DROP RULE` drops a rewrite rule.

## Parameters

`IF EXISTS`

Do not throw an error if the rule does not exist. A notice is issued in this case.

*name*

The name of the rule to drop.

*relation*

The name (optionally schema-qualified) of the table or view that the rule applies to.

`CASCADE`

Automatically drop objects that depend on the rule.

`RESTRICT`

Refuse to drop the rule if any objects depend on it. This is the default.

## Examples

To drop the rewrite rule `newrule`:

```
DROP RULE newrule ON mytable;
```

## Compatibility

There is no `DROP RULE` statement in the SQL standard.

## **See Also**

*CREATE RULE*

# DROP SCHEMA

## Name

`DROP SCHEMA` — remove a schema

## Synopsis

```
DROP SCHEMA [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP SCHEMA` removes schemas from the database.

A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if he does not own some of the objects within the schema.

## Parameters

`IF EXISTS`

Do not throw an error if the schema does not exist. A notice is issued in this case.

*name*

The name of a schema.

`CASCADE`

Automatically drop objects (tables, functions, etc.) that are contained in the schema.

`RESTRICT`

Refuse to drop the schema if it contains any objects. This is the default.

## Examples

To remove schema `mystuff` from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

## Compatibility

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command, and apart from the `IF EXISTS` option, which is a PostgreSQL extension.

## See Also

*ALTER SCHEMA*, *CREATE SCHEMA*

# DROP SEQUENCE

## Name

`DROP SEQUENCE` — remove a sequence

## Synopsis

```
DROP SEQUENCE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP SEQUENCE` removes sequence number generators. A sequence can only be dropped by its owner or a superuser.

## Parameters

`IF EXISTS`

Do not throw an error if the sequence does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of a sequence.

`CASCADE`

Automatically drop objects that depend on the sequence.

`RESTRICT`

Refuse to drop the sequence if any objects depend on it. This is the default.

## Examples

To remove the sequence `serial`:

```
DROP SEQUENCE serial;
```

## Compatibility

`DROP SEQUENCE` conforms to the SQL standard, except that the standard only allows one sequence to be dropped per command, and apart from the `IF EXISTS` option, which is a PostgreSQL extension.

## **See Also**

*CREATE SEQUENCE, ALTER SEQUENCE*

# DROP TABLE

## Name

DROP TABLE — remove a table

## Synopsis

```
DROP TABLE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

DROP TABLE removes tables from the database. Only its owner can drop a table. To empty a table of rows without destroying the table, use *DELETE* or *TRUNCATE*.

DROP TABLE always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view or a foreign-key constraint of another table, CASCADE must be specified. (CASCADE will remove a dependent view entirely, but in the foreign-key case it will only remove the foreign-key constraint, not the other table entirely.)

## Parameters

IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the table to drop.

CASCADE

Automatically drop objects that depend on the table (such as views).

RESTRICT

Refuse to drop the table if any objects depend on it. This is the default.

## Examples

To destroy two tables, `films` and `distributors`:

```
DROP TABLE films, distributors;
```

## Compatibility

This command conforms to the SQL standard, except that the standard only allows one table to be dropped per command, and apart from the `IF EXISTS` option, which is a PostgreSQL extension.

## See Also

*ALTER TABLE*, *CREATE TABLE*

# DROP TABLESPACE

## Name

DROP TABLESPACE — remove a tablespace

## Synopsis

```
DROP TABLESPACE [ IF EXISTS ] tablespacename
```

## Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases might still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the `temp_tablespaces` setting of any active session, the DROP might fail due to temporary files residing in the tablespace.

## Parameters

IF EXISTS

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

*tablespacename*

The name of a tablespace.

## Notes

DROP TABLESPACE cannot be executed inside a transaction block.

## Examples

To remove tablespace `mystuff` from the system:

```
DROP TABLESPACE mystuff;
```

## Compatibility

`DROP TABLESPACE` is a PostgreSQL extension.

## See Also

*CREATE TABLESPACE*, *ALTER TABLESPACE*

# DROP TEXT SEARCH CONFIGURATION

## Name

DROP TEXT SEARCH CONFIGURATION — remove a text search configuration

## Synopsis

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH CONFIGURATION drops an existing text search configuration. To execute this command you must be the owner of the configuration.

## Parameters

IF EXISTS

Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search configuration.

CASCADE

Automatically drop objects that depend on the text search configuration.

RESTRICT

Refuse to drop the text search configuration if any objects depend on it. This is the default.

## Examples

Remove the text search configuration `my_english`:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add `CASCADE` to drop such indexes along with the text search configuration.

## Compatibility

There is no DROP TEXT SEARCH CONFIGURATION statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH CONFIGURATION, CREATE TEXT SEARCH CONFIGURATION*

# DROP TEXT SEARCH DICTIONARY

## Name

DROP TEXT SEARCH DICTIONARY — remove a text search dictionary

## Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH DICTIONARY drops an existing text search dictionary. To execute this command you must be the owner of the dictionary.

## Parameters

IF EXISTS

Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search dictionary.

CASCADE

Automatically drop objects that depend on the text search dictionary.

RESTRICT

Refuse to drop the text search dictionary if any objects depend on it. This is the default.

## Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

## Compatibility

There is no DROP TEXT SEARCH DICTIONARY statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH DICTIONARY, CREATE TEXT SEARCH DICTIONARY*

# DROP TEXT SEARCH PARSER

## Name

`DROP TEXT SEARCH PARSER` — remove a text search parser

## Synopsis

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

`DROP TEXT SEARCH PARSER` drops an existing text search parser. You must be a superuser to use this command.

## Parameters

`IF EXISTS`

Do not throw an error if the text search parser does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search parser.

`CASCADE`

Automatically drop objects that depend on the text search parser.

`RESTRICT`

Refuse to drop the text search parser if any objects depend on it. This is the default.

## Examples

Remove the text search parser `my_parser`:

```
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add `CASCADE` to drop such configurations along with the parser.

## Compatibility

There is no `DROP TEXT SEARCH PARSER` statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH PARSER, CREATE TEXT SEARCH PARSER*

# DROP TEXT SEARCH TEMPLATE

## Name

DROP TEXT SEARCH TEMPLATE — remove a text search template

## Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] name [ CASCADE | RESTRICT ]
```

## Description

DROP TEXT SEARCH TEMPLATE drops an existing text search template. You must be a superuser to use this command.

## Parameters

IF EXISTS

Do not throw an error if the text search template does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of an existing text search template.

CASCADE

Automatically drop objects that depend on the text search template.

RESTRICT

Refuse to drop the text search template if any objects depend on it. This is the default.

## Examples

Remove the text search template `thesaurus`:

```
DROP TEXT SEARCH TEMPLATE thesaurus;
```

This command will not succeed if there are any existing text search dictionaries that use the template. Add `CASCADE` to drop such dictionaries along with the template.

## Compatibility

There is no DROP TEXT SEARCH TEMPLATE statement in the SQL standard.

## **See Also**

*ALTER TEXT SEARCH TEMPLATE, CREATE TEXT SEARCH TEMPLATE*

# DROP TRIGGER

## Name

DROP TRIGGER — remove a trigger

## Synopsis

```
DROP TRIGGER [ IF EXISTS ] name ON table [ CASCADE | RESTRICT ]
```

## Description

DROP TRIGGER removes an existing trigger definition. To execute this command, the current user must be the owner of the table for which the trigger is defined.

## Parameters

IF EXISTS

Do not throw an error if the trigger does not exist. A notice is issued in this case.

*name*

The name of the trigger to remove.

*table*

The name (optionally schema-qualified) of the table for which the trigger is defined.

CASCADE

Automatically drop objects that depend on the trigger.

RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

## Examples

Destroy the trigger `if_dist_exists` on the table `films`:

```
DROP TRIGGER if_dist_exists ON films;
```

## Compatibility

The `DROP TRIGGER` statement in PostgreSQL is incompatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply `DROP TRIGGER name`.

## See Also

*CREATE TRIGGER*

# DROP TYPE

## Name

`DROP TYPE` — remove a data type

## Synopsis

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP TYPE` removes a user-defined data type. Only the owner of a type can remove it.

## Parameters

`IF EXISTS`

Do not throw an error if the type does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the data type to remove.

`CASCADE`

Automatically drop objects that depend on the type (such as table columns, functions, operators).

`RESTRICT`

Refuse to drop the type if any objects depend on it. This is the default.

## Examples

To remove the data type `box`:

```
DROP TYPE box;
```

## Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a PostgreSQL extension. But note that the `CREATE TYPE` command and the data type extension mechanisms in PostgreSQL differ from the SQL standard.

## **See Also**

*CREATE TYPE, ALTER TYPE*

# DROP USER

## Name

`DROP USER` — remove a database role

## Synopsis

```
DROP USER [ IF EXISTS ] name [, ...]
```

## Description

`DROP USER` is now an alias for *DROP ROLE*.

## Compatibility

The `DROP USER` statement is a PostgreSQL extension. The SQL standard leaves the definition of users to the implementation.

## See Also

*DROP ROLE*

# DROP VIEW

## Name

`DROP VIEW` — remove a view

## Synopsis

```
DROP VIEW [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP VIEW` drops an existing view. To execute this command you must be the owner of the view.

## Parameters

`IF EXISTS`

Do not throw an error if the view does not exist. A notice is issued in this case.

*name*

The name (optionally schema-qualified) of the view to remove.

`CASCADE`

Automatically drop objects that depend on the view (such as other views).

`RESTRICT`

Refuse to drop the view if any objects depend on it. This is the default.

## Examples

This command will remove the view called `kinds`:

```
DROP VIEW kinds;
```

## Compatibility

This command conforms to the SQL standard, except that the standard only allows one view to be dropped per command, and apart from the `IF EXISTS` option, which is a PostgreSQL extension.

## **See Also**

*ALTER VIEW, CREATE VIEW*

# END

## Name

END — commit the current transaction

## Synopsis

```
END [ WORK | TRANSACTION ]
```

## Description

END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a PostgreSQL extension that is equivalent to *COMMIT*.

## Parameters

WORK  
TRANSACTION

Optional key words. They have no effect.

## Notes

Use *ROLLBACK* to abort a transaction.

Issuing END when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To commit the current transaction and make all changes permanent:

```
END;
```

## Compatibility

END is a PostgreSQL extension that provides functionality equivalent to *COMMIT*, which is specified in the SQL standard.

## **See Also**

*BEGIN, COMMIT, ROLLBACK*

# EXECUTE

## Name

EXECUTE — execute a prepared statement

## Synopsis

```
EXECUTE name [ ( parameter [, ...] ) ]
```

## Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.

If the PREPARE statement that created the statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see *PREPARE*.

## Parameters

*name*

The name of the prepared statement to execute.

*parameter*

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

## Outputs

The command tag returned by EXECUTE is that of the prepared statement, and not EXECUTE.

## Examples

Examples are given in the *Examples* section of the *PREPARE* documentation.

## **Compatibility**

The SQL standard includes an `EXECUTE` statement, but it is only for use in embedded SQL. This version of the `EXECUTE` statement also uses a somewhat different syntax.

## **See Also**

*DEALLOCATE, PREPARE*

# EXPLAIN

## Name

EXPLAIN — show the execution plan of a statement

## Synopsis

```
EXPLAIN [ ANALYZE ] [ VERBOSE ] statement
```

## Description

This command displays the execution plan that the PostgreSQL planner generates for the supplied statement. The execution plan shows how the table(s) referenced by the statement will be scanned — by plain sequential scan, index scan, etc. — and if multiple tables are referenced, what join algorithms will be used to bring together the required rows from each input table.

The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement (measured in units of disk page fetches). Actually two numbers are shown: the start-up time before the first row can be returned, and the total time to return all the rows. For most queries the total time is what matters, but in contexts such as a subquery in `EXISTS`, the planner will choose the smallest start-up time instead of the smallest total time (since the executor will stop after getting one row, anyway). Also, if you limit the number of rows to return with a `LIMIT` clause, the planner makes an appropriate interpolation between the endpoint costs to estimate which plan is really the cheapest.

The `ANALYZE` option causes the statement to be actually executed, not only planned. The total elapsed time expended within each plan node (in milliseconds) and total number of rows it actually returned are added to the display. This is useful for seeing whether the planner's estimates are close to reality.

**Important:** Keep in mind that the statement is actually executed when the `ANALYZE` option is used. Although `EXPLAIN` will discard any output that a `SELECT` would return, other side effects of the statement will happen as usual. If you wish to use `EXPLAIN ANALYZE` on an `INSERT`, `UPDATE`, `DELETE`, or `EXECUTE` statement without letting the command affect your data, use this approach:

```
BEGIN;  
EXPLAIN ANALYZE ...;  
ROLLBACK;
```

## Parameters

### ANALYZE

Carry out the command and show the actual run times.

### VERBOSE

Show the full internal representation of the plan tree, rather than just a summary. Usually this option is only useful for specialized debugging purposes. The `VERBOSE` output is either pretty-printed or not, depending on the setting of the `explain_pretty_print` configuration parameter.

### statement

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `VALUES`, `EXECUTE`, or `DECLARE` statement, whose execution plan you wish to see.

## Notes

There is only sparse documentation on the optimizer's use of cost information in PostgreSQL. Refer to Section 14.1 for more information.

In order to allow the PostgreSQL query planner to make reasonably informed decisions when optimizing queries, the `ANALYZE` statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan might be chosen.

Genetic query optimization (GEQO) randomly tests execution plans. Therefore, when the number of join relations exceeds `geqo_threshold` causing genetic query optimization to be used, the execution plan is likely to change each time the statement is executed.

In order to measure the run-time cost of each node in the execution plan, the current implementation of `EXPLAIN ANALYZE` can add considerable profiling overhead to query execution. As a result, running `EXPLAIN ANALYZE` on a query can sometimes take significantly longer than executing the query normally. The amount of overhead depends on the nature of the query.

## Examples

To show the plan for a simple query on a table with a single `integer` column and 10000 rows:

```
EXPLAIN SELECT * FROM foo;
```

```

                                QUERY PLAN
-----
Seq Scan on foo  (cost=0.00..155.00 rows=10000 width=4)
(1 row)
```

If there is an index and we use a query with an indexable `WHERE` condition, `EXPLAIN` might show a different plan:

```
EXPLAIN SELECT * FROM foo WHERE i = 4;
```

QUERY PLAN

```
-----
Index Scan using fi on foo  (cost=0.00..5.98 rows=1 width=4)
  Index Cond: (i = 4)
(2 rows)
```

Here is an example of a query plan for a query using an aggregate function:

```
EXPLAIN SELECT sum(i) FROM foo WHERE i < 10;
```

QUERY PLAN

```
-----
Aggregate  (cost=23.93..23.93 rows=1 width=4)
  -> Index Scan using fi on foo  (cost=0.00..23.92 rows=6 width=4)
      Index Cond: (i < 10)
(3 rows)
```

Here is an example of using `EXPLAIN EXECUTE` to display the execution plan for a prepared query:

```
PREPARE query(int, int) AS SELECT sum(bar) FROM test
  WHERE id > $1 AND id < $2
  GROUP BY foo;
```

```
EXPLAIN ANALYZE EXECUTE query(100, 200);
```

QUERY PLAN

```
-----
HashAggregate  (cost=39.53..39.53 rows=1 width=8) (actual time=0.661..0.672 rows=7 loops=1)
  -> Index Scan using test_pkey on test  (cost=0.00..32.97 rows=1311 width=8) (actual time=0.000..0.001 rows=7 loops=1)
      Index Cond: ((id > $1) AND (id < $2))
  Total runtime: 0.851 ms
(4 rows)
```

Of course, the specific numbers shown here depend on the actual contents of the tables involved. Also note that the numbers, and even the selected query strategy, might vary between PostgreSQL releases due to planner improvements. In addition, the `ANALYZE` command uses random sampling to estimate data statistics; therefore, it is possible for cost estimates to change after a fresh run of `ANALYZE`, even if the actual distribution of data in the table has not changed.

## Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

## **See Also**

*ANALYZE*

# FETCH

## Name

FETCH — retrieve rows from a query using a cursor

## Synopsis

```
FETCH [ direction { FROM | IN } ] cursorname
```

where *direction* can be empty or one of:

```
NEXT
PRIOR
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
BACKWARD
BACKWARD count
BACKWARD ALL
```

## Description

FETCH retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If FETCH runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward. FETCH ALL or FETCH BACKWARD ALL will always leave the cursor positioned after the last row or before the first row.

The forms NEXT, PRIOR, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD and BACKWARD retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row (or after/before all rows, if the *count* exceeds the number of rows available).

RELATIVE 0, FORWARD 0, and BACKWARD 0 all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row; in which case, no row is returned.

## Parameters

*direction*

*direction* defines the fetch direction and number of rows to fetch. It can be one of the following:

NEXT

Fetch the next row. This is the default if *direction* is omitted.

PRIOR

Fetch the prior row.

FIRST

Fetch the first row of the query (same as ABSOLUTE 1).

LAST

Fetch the last row of the query (same as ABSOLUTE -1).

ABSOLUTE *count*

Fetch the *count*'th row of the query, or the  $\text{abs}(\text{count})$ 'th row from the end if *count* is negative. Position before first row or after last row if *count* is out of range; in particular, ABSOLUTE 0 positions before the first row.

RELATIVE *count*

Fetch the *count*'th succeeding row, or the  $\text{abs}(\text{count})$ 'th prior row if *count* is negative. RELATIVE 0 re-fetches the current row, if any.

*count*

Fetch the next *count* rows (same as FORWARD *count*).

ALL

Fetch all remaining rows (same as FORWARD ALL).

FORWARD

Fetch the next row (same as NEXT).

FORWARD *count*

Fetch the next *count* rows. FORWARD 0 re-fetches the current row.

FORWARD ALL

Fetch all remaining rows.

BACKWARD

Fetch the prior row (same as PRIOR).

BACKWARD *count*

Fetch the prior *count* rows (scanning backwards). BACKWARD 0 re-fetches the current row.

BACKWARD ALL

Fetch all prior rows (scanning backwards).

*count*

*count* is a possibly-signed integer constant, determining the location or number of rows to fetch. For FORWARD and BACKWARD cases, specifying a negative *count* is equivalent to changing the sense of FORWARD and BACKWARD.

*cursorname*

An open cursor's name.

## Outputs

On successful completion, a FETCH command returns a command tag of the form

```
FETCH count
```

The *count* is the number of rows fetched (possibly zero). Note that in psql, the command tag will not actually be displayed, since psql displays the fetched rows instead.

## Notes

The cursor should be declared with the SCROLL option if one intends to use any variants of FETCH other than FETCH NEXT or FETCH FORWARD with a positive count. For simple queries PostgreSQL will allow backwards fetch from cursors not declared with SCROLL, but this behavior is best not relied on. If the cursor is declared with NO SCROLL, no backward fetches are allowed.

ABSOLUTE fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway. Negative absolute fetches are even worse: the query must be read to the end to find the last row, and then traversed backward from there. However, rewinding to the start of the query (as with FETCH ABSOLUTE 0) is fast.

DECLARE is used to define a cursor. Use MOVE to change cursor position without retrieving data.

## Examples

The following example traverses a table using a cursor:

```
BEGIN WORK;

-- Set up a cursor:
DECLARE liahona SCROLL CURSOR FOR SELECT * FROM films;

-- Fetch the first 5 rows in the cursor liahona:
FETCH FORWARD 5 FROM liahona;
```

code	title	did	date_prod	kind	len
BL101	The Third Man	101	1949-12-23	Drama	01:44
BL102	The African Queen	101	1951-08-11	Romantic	01:43
JL201	Une Femme est une Femme	102	1961-03-12	Romantic	01:25

```

P_301 | Vertigo          | 103 | 1958-11-14 | Action | 02:08
P_302 | Becket              | 103 | 1964-02-03 | Drama  | 02:28

-- Fetch the previous row:
FETCH PRIOR FROM liahona;

code | title | did | date_prod | kind | len
-----+-----+-----+-----+-----+-----
P_301 | Vertigo | 103 | 1958-11-14 | Action | 02:08

-- Close the cursor and end the transaction:
CLOSE liahona;
COMMIT WORK;
```

## Compatibility

The SQL standard defines `FETCH` for use in embedded SQL only. The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD` and `BACKWARD`, as well as the forms `FETCH count` and `FETCH ALL`, in which `FORWARD` is implicit, are PostgreSQL extensions.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN` is an extension.

TO { [ GROUP ] rolename | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT role [, ...] TO rolename [, ...] [ WITH ADMIN OPTION ]
```

## Description

The GRANT command has two basic variants: one that grants privileges on a database object (table, view, sequence, database, function, procedural language, schema, or tablespace), and one that grants membership in a role. These variants are similar in many ways, but they are different enough to be described separately.

As of PostgreSQL 8.1, the concepts of users and groups have been unified into a single kind of entity called a role. It is therefore no longer necessary to use the keyword `GROUP` to identify whether a grantee is a user or a group. `GROUP` is still allowed in the command, but it is a noise word.

## GRANT on Database Objects

This variant of the `GRANT` command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word `PUBLIC` indicates that the privileges are to be granted to all roles, including those that might be created later. `PUBLIC` can be thought of as an implicitly defined group that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`.

If `WITH GRANT OPTION` is specified, the recipient of the privilege can in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to `PUBLIC`.

There is no need to grant privileges to the owner of an object (usually the user that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of his own privileges for safety.) The right to drop an object, or to alter its definition in any way is not described by a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. The owner implicitly has all grant options for the object, too.

Depending on the type of object, the initial default privileges might include granting some privileges to `PUBLIC`. The default is no public access for tables, schemas, and tablespaces; `CONNECT` privilege and `TEMP` table creation privilege for databases; `EXECUTE` privilege for functions; and `USAGE` privilege for languages. The object owner can of course revoke these privileges. (For maximum security, issue the `REVOKE` in the same transaction that creates the object; then there is no window in which another user can use the object.)

The possible privileges are:

### SELECT

Allows *SELECT* from any column of the specified table, view, or sequence. Also allows the use of *COPY TO*. For sequences, this privilege also allows the use of the `currval` function.

### INSERT

Allows *INSERT* of a new row into the specified table. Also allows *COPY FROM*.

### UPDATE

Allows *UPDATE* of any column of the specified table. `SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE` also require this privilege (besides the `SELECT` privilege). For sequences, this privilege allows the use of the `nextval` and `setval` functions.

### DELETE

Allows *DELETE* of a row from the specified table.

### REFERENCES

To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced tables.

**TRIGGER**

Allows the creation of a trigger on the specified table. (See the *CREATE TRIGGER* statement.)

**CREATE**

For databases, allows new schemas to be created within the database.

For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object *and* have this privilege for the containing schema.

For tablespaces, allows tables, indexes, and temporary files to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

**CONNECT**

Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by `pg_hba.conf`).

**TEMPORARY****TEMP**

Allows temporary tables to be created while using the database.

**EXECUTE**

Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

**USAGE**

For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.

For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to “look up” objects within the schema. Without this permission, it is still possible to see the object names, e.g. by querying the system tables. Also, after revoking this permission, existing backends might have statements that have previously performed this lookup, so this is not a completely secure way to prevent object access.

For sequences, this privilege allows the use of the `currval` and `nextval` functions.

**ALL PRIVILEGES**

Grant all of the available privileges at once. The `PRIVILEGES` key word is optional in PostgreSQL, though it is required by strict SQL.

The privileges required by other commands are listed on the reference page of the respective command.

**GRANT on Roles**

This variant of the `GRANT` command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If `WITH ADMIN OPTION` is specified, the member can in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. However,

database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`. Note also that this form of the command does not allow the noise word `GROUP`.

## Notes

The *REVOKE* command is used to revoke access privileges.

When a non-owner of an object attempts to `GRANT` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will grant only those privileges for which the user has grant options. The `GRANT ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

It should be noted that database superusers can access all objects regardless of object privilege settings. This is comparable to the rights of `root` in a Unix system. As with `root`, it's unwise to operate as a superuser except when absolutely necessary.

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. (For role membership, the membership appears to have been granted by the containing role itself.)

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can grant privileges on `t1` to `u2`, but those privileges will appear to have been granted directly by `g1`. Any other member of role `g1` could revoke them later.

If the role executing `GRANT` holds the required privileges indirectly via more than one role membership path, it is unspecified which containing role will be recorded as having done the grant. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `GRANT` as.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on sequence must be set separately.

Currently, PostgreSQL does not support granting or revoking privileges for individual columns of a table. One possible workaround is to create a view having just the desired columns and then grant privileges to that view.

Use `psql's \z` command to obtain information about existing privileges, for example:

```
=> \z mytable
Access privileges for database "lusitania"
Schema | Name | Type | Access privileges
-----+-----+-----+-----
public | mytable | table | {miriam=arwdxt/miriam,=r/miriam,admin=arw/miriam}
```

(1 row)

The entries shown by \z are interpreted thus:

```

rolename=xxxx -- privileges granted to a role
=xxxx -- privileges granted to PUBLIC

r -- SELECT ("read")
w -- UPDATE ("write")
a -- INSERT ("append")
d -- DELETE
x -- REFERENCES
t -- TRIGGER
X -- EXECUTE
U -- USAGE
C -- CREATE
c -- CONNECT
T -- TEMPORARY
arwdxt -- ALL PRIVILEGES (for tables)
* -- grant option for preceding privilege

/yyyy -- role that granted this privilege

```

The above example display would be seen by user `miriam` after creating table `mytable` and doing:

```

GRANT SELECT ON mytable TO PUBLIC;
GRANT SELECT, UPDATE, INSERT ON mytable TO admin;

```

If the “Access privileges” column is empty for a given object, it means the object has default privileges (that is, its privileges column is null). Default privileges always include all privileges for the owner, and can include some privileges for `PUBLIC` depending on the object type, as explained above. The first `GRANT` or `REVOKE` on an object will instantiate the default privileges (producing, for example, `{miriam=arwdxt/miriam}`) and then modify them per the specified request.

Notice that the owner’s implicit grant options are not marked in the access privileges display. A `*` will appear only when grant options have been explicitly granted to someone.

## Examples

Grant insert privilege to all users on table `films`:

```

GRANT INSERT ON films TO PUBLIC;

```

Grant all available privileges to user `manuel` on view `kinds`:

```

GRANT ALL PRIVILEGES ON kinds TO manuel;

```

Note that while the above will indeed grant all privileges if executed by a superuser or the owner of `kinds`, when executed by someone else it will only grant those permissions for which the someone else has grant options.

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```

## Compatibility

According to the SQL standard, the `PRIVILEGES` key word in `ALL PRIVILEGES` is required. The SQL standard does not support setting the privileges on more than one object per command.

PostgreSQL allows an object owner to revoke his own ordinary privileges: for example, a table owner can make the table read-only to himself by revoking his own `INSERT`, `UPDATE`, and `DELETE` privileges. This is not possible according to the SQL standard. The reason is that PostgreSQL treats the owner's privileges as having been granted by the owner to himself; therefore he can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed entity “`_SYSTEM`”. Not being “`_SYSTEM`”, the owner cannot revoke these rights.

PostgreSQL does not support the SQL-standard functionality of setting privileges for individual columns.

The SQL standard provides for a `USAGE` privilege on other kinds of objects: character sets, collations, translations, domains.

Privileges on databases, tablespaces, schemas, and languages are PostgreSQL extensions.

*REVOKE*

# INSERT

## Name

INSERT — create new rows in a table

## Synopsis

```
INSERT INTO table [ ( column [, ...] ) ]  
    { DEFAULT VALUES | VALUES ( { expression | DEFAULT } [, ...] ) [, ...] | query }  
    [ RETURNING * | output_expression [ AS output_name ] [, ...] ]
```

## Description

INSERT inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order; or the first *N* column names, if there are only *N* columns supplied by the VALUES clause or *query*. The values supplied by the VALUES clause or *query* are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is none.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

The optional RETURNING clause causes INSERT to compute and return value(s) based on each row actually inserted. This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have INSERT privilege on a table in order to insert into it, and SELECT privilege on it to use RETURNING. If you use the *query* clause to insert rows from a query, you also need to have SELECT privilege on any table used in the query.

## Parameters

*table*

The name (optionally schema-qualified) of an existing table.

*column*

The name of a column in *table*. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.)

**DEFAULT VALUES**

All columns will be filled with their default values.

*expression*

An expression or value to assign to the corresponding *column*.

**DEFAULT**

The corresponding *column* will be filled with its default value.

*query*

A query (*SELECT* statement) that supplies the rows to be inserted. Refer to the *SELECT* statement for a description of the syntax.

*output\_expression*

An expression to be computed and returned by the *INSERT* command after each row is inserted. The expression can use any column names of the *table*. Write *\** to return all columns of the inserted row(s).

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, an *INSERT* command returns a command tag of the form

```
INSERT oid count
```

The *count* is the number of rows inserted. If *count* is exactly one, and the target table has OIDs, then *oid* is the OID assigned to the inserted row. Otherwise *oid* is zero.

If the *INSERT* command contains a *RETURNING* clause, the result will be similar to that of a *SELECT* statement containing the columns and values defined in the *RETURNING* list, computed over the row(s) inserted by the command.

## Examples

Insert a single row into table *films*:

```
INSERT INTO films VALUES
    ('UA502', 'Bananas', 105, '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the *len* column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the date columns rather than specifying a value:

```
INSERT INTO films VALUES
    ('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes');
INSERT INTO films (code, title, did, date_prod, kind)
    VALUES ('T_601', 'Yojimbo', 106, DEFAULT, 'Drama');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
    ('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
    ('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

This example inserts into array columns:

```
-- Create an empty 3x3 gameboard for noughts-and-crosses
INSERT INTO tictactoe (game, board[1:3][1:3])
    VALUES (1, '{{" "," "," "," "},{ " "," "," "," "},{ " "," "," "," "}}');
-- The subscripts in the above example aren't really needed
INSERT INTO tictactoe (game, board)
    VALUES (2, '{{X," "," "," "},{ " ",O," "},{ " ",X," "}}');
```

Insert a single row into table `distributors`, returning the sequence number generated by the `DEFAULT` clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
    RETURNING did;
```

## Compatibility

`INSERT` conforms to the SQL standard, except that the `RETURNING` clause is a PostgreSQL extension. Also, the case in which a column name list is omitted, but not all the columns are filled from the `VALUES` clause or *query*, is disallowed by the standard.

Possible limitations of the *query* clause are documented under *SELECT*.

# LISTEN

## Name

LISTEN — listen for a notification

## Synopsis

LISTEN *name*

## Description

LISTEN registers the current session as a listener on the notification condition *name*. If the current session is already registered as a listener for this notification condition, nothing is done.

Whenever the command NOTIFY *name* is invoked, either by this session or another one connected to the same database, all the sessions currently listening on that notification condition are notified, and each will in turn notify its connected client application. See the discussion of NOTIFY for more information.

A session can be unregistered for a given notify condition with the UNLISTEN command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which PostgreSQL application programming interface it uses. With the libpq library, the application issues LISTEN as an ordinary SQL command, and then must periodically call the function PQnotifies to find out whether any notification events have been received. Other interfaces such as libpqtc1 provide higher-level methods for handling notify events; indeed, with libpqtc1 the application programmer should not even issue LISTEN or UNLISTEN directly. See the documentation for the interface you are using for more details.

NOTIFY contains a more extensive discussion of the use of LISTEN and NOTIFY.

## Parameters

*name*

Name of a notify condition (any identifier).

## Examples

Configure and execute a listen/notify sequence from psql:

```
LISTEN virtual;  
NOTIFY virtual;  
Asynchronous notification "virtual" received from server process with PID 8448.
```

## **Compatibility**

There is no `LISTEN` statement in the SQL standard.

## **See Also**

*NOTIFY, UNLISTEN*

# LOAD

## Name

LOAD — load or reload a shared library file

## Synopsis

```
LOAD 'filename'
```

## Description

This command loads a shared library file into the PostgreSQL server's address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the *CREATE FUNCTION* command.

The file name is specified in the same way as for shared library names in *CREATE FUNCTION*; in particular, one can rely on a search path and automatic addition of the system's standard shared library file name extension. See Section 34.9 for more information on this topic.

Non-superusers can only apply `LOAD` to library files located in `$libdir/plugins/` — the specified *filename* must begin with exactly that string. (It is the database administrator's responsibility to ensure that only “safe” libraries are installed there.)

## Compatibility

LOAD is a PostgreSQL extension.

## See Also

*CREATE FUNCTION*

# LOCK

## Name

LOCK — lock a table

## Synopsis

```
LOCK [ TABLE ] name [, ...] [ IN lockmode MODE ] [ NOWAIT ]
```

where *lockmode* is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE  
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

## Description

LOCK TABLE obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If NOWAIT is specified, LOCK TABLE does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. (There is no UNLOCK TABLE command; locks are always released at transaction end.)

When acquiring locks automatically for commands that reference tables, PostgreSQL always uses the least restrictive lock mode possible. LOCK TABLE provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the Read Committed isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain SHARE lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because SHARE lock mode conflicts with the ROW EXCLUSIVE lock acquired by writers, and your LOCK TABLE *name* IN SHARE MODE statement will wait until any concurrent holders of ROW EXCLUSIVE mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the Serializable isolation level, you have to execute the LOCK TABLE statement before executing any SELECT or data modification statement. A serializable transaction's view of data will be frozen when its first SELECT or data modification statement begins. A LOCK TABLE later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use SHARE ROW EXCLUSIVE lock mode instead of SHARE mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire SHARE mode, and then be unable to also acquire ROW EXCLUSIVE mode to actually perform their updates. (Note that a transaction's own locks never conflict, so a transaction can acquire ROW EXCLUSIVE mode when it holds SHARE mode — but not if anyone else holds SHARE mode.) To avoid deadlocks, make sure all transactions acquire locks

on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

More information about the lock modes and locking strategies can be found in Section 13.3.

## Parameters

*name*

The name (optionally schema-qualified) of an existing table to lock.

The command `LOCK TABLE a, b;` is equivalent to `LOCK TABLE a; LOCK TABLE b;`. The tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

*lockmode*

The lock mode specifies which locks this lock conflicts with. Lock modes are described in Section 13.3.

If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used.

`NOWAIT`

Specifies that `LOCK TABLE` should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

## Notes

`LOCK TABLE ... IN ACCESS SHARE MODE` requires `SELECT` privileges on the target table. All other forms of `LOCK` require `UPDATE` and/or `DELETE` privileges.

`LOCK TABLE` is useful only inside a transaction block (`BEGIN/COMMIT` pair), since the lock is dropped as soon as the transaction ends. A `LOCK TABLE` command appearing outside any transaction block forms a self-contained transaction, so the lock will be dropped as soon as it is obtained.

`LOCK TABLE` only deals with table-level locks, and so the mode names involving `ROW` are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, `ROW EXCLUSIVE` mode is a sharable table lock. Keep in mind that all the lock modes have identical semantics so far as `LOCK TABLE` is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see Section 13.3.2 and the *FOR UPDATE/FOR SHARE Clause* in the `SELECT` reference documentation.

## Examples

Obtain a `SHARE` lock on a primary key table when going to perform inserts into a foreign key table:

```
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
  WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
```

```
INSERT INTO films_user_comments VALUES
  (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a primary key table when going to perform a delete operation:

```
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
  (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

## Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. PostgreSQL supports that too; see *SET TRANSACTION* for details.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the PostgreSQL lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

# MOVE

## Name

MOVE — position a cursor

## Synopsis

```
MOVE [ direction { FROM | IN } ] cursorname
```

## Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the FETCH command, except it only positions the cursor and does not return rows.

Refer to *FETCH* for details on syntax and usage.

## Outputs

On successful completion, a MOVE command returns a command tag of the form

```
MOVE count
```

The *count* is the number of rows that a FETCH command with the same parameters would have returned (possibly zero).

## Examples

```
BEGIN WORK;
DECLARE liahona CURSOR FOR SELECT * FROM films;

-- Skip the first 5 rows:
MOVE FORWARD 5 IN liahona;
MOVE 5

-- Fetch the 6th row from the cursor liahona:
FETCH 1 FROM liahona;
  code | title   | did | date_prod | kind | len
-----+-----+-----+-----+-----+-----
  P_303 | 48 Hrs   | 103 | 1982-10-22 | Action | 01:37
(1 row)

-- Close the cursor liahona and end the transaction:
CLOSE liahona;
COMMIT WORK;
```

## **Compatibility**

There is no *MOVE* statement in the SQL standard.

## **See Also**

*CLOSE, DECLARE, FETCH*

# NOTIFY

## Name

NOTIFY — generate a notification

## Synopsis

NOTIFY *name*

## Description

The `NOTIFY` command sends a notification event to each client application that has previously executed `LISTEN name` for the specified notification name in the current database.

`NOTIFY` provides a simple form of signal or interprocess communication mechanism for a collection of processes accessing the same PostgreSQL database. Higher-level mechanisms can be built by using tables in the database to pass additional data (beyond a mere notification name) from notifier to listener(s).

The information passed to the client for a notification event includes the notification name and the notifying session's server process PID. It is up to the database designer to define the notification names that will be used in a given database and what each one means.

Commonly, the notification name is the same as the name of some table in the database, and the notify event essentially means, "I changed this table, take a look at it to see what's new". But no such association is enforced by the `NOTIFY` and `LISTEN` commands. For example, a database designer could use several different notification names to signal different sorts of changes to a single table.

When `NOTIFY` is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the `NOTIFY` in a rule that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

`NOTIFY` interacts with SQL transactions in some important ways. Firstly, if a `NOTIFY` is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including `NOTIFY`. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot "take back" a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using `NOTIFY` for real-time signaling should try to keep their transactions short.

`NOTIFY` behaves like Unix signals in one important respect: if the same notification name is signaled multiple times in quick succession, recipients might get only one notification event for several executions of `NOTIFY`. So it is a bad idea to depend on the number of notifications received. Instead, use `NOTIFY`

to wake up applications that need to pay attention to something, and use a database object (such as a sequence) to keep track of what happened or how many times it happened.

It is common for a client that executes `NOTIFY` to be listening on the same notification name itself. In that case it will get back a notification event, just like all the other listening sessions. Depending on the application logic, this could result in useless work, for example, reading a database table to find the same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether the notifying session's server process PID (supplied in the notification event message) is the same as one's own session's PID (available from `libpq`). When they are the same, the notification event is one's own work bouncing back, and can be ignored. (Despite what was said in the preceding paragraph, this is a safe technique. PostgreSQL keeps self-notifications separate from notifications arriving from other sessions, so you cannot miss an outside notification by ignoring your own notifications.)

## Parameters

*name*

Name of the notification to be signaled (any identifier).

## Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;  
NOTIFY virtual;  
Asynchronous notification "virtual" received from server process with PID 8448.
```

## Compatibility

There is no `NOTIFY` statement in the SQL standard.

## See Also

*LISTEN*, *UNLISTEN*

# PREPARE

## Name

PREPARE — prepare a statement for execution

## Synopsis

```
PREPARE name [ ( datatype [, ...] ) ] AS statement
```

## Description

PREPARE creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the PREPARE statement is executed, the specified statement is parsed, rewritten, and planned. When an EXECUTE command is subsequently issued, the prepared statement need only be executed. Thus, the parsing, rewriting, and planning stages are only performed once, instead of every time the statement is executed.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using \$1, \$2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as `unknown`, the type is inferred from the context in which the parameter is used (if possible). When executing the statement, specify the actual values for these parameters in the EXECUTE statement. Refer to *EXECUTE* for more information about that.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. The prepared statement can be manually cleaned up using the *DEALLOCATE* command.

Prepared statements have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

## Parameters

*name*

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

*datatype*

The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as `unknown`, it will be inferred from the context in which the parameter is used. To refer to the parameters in the prepared statement itself, use `$1`, `$2`, etc.

*statement*

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `VALUES` statement.

## Notes

In some situations, the query plan produced for a prepared statement will be inferior to the query plan that would have been chosen if the statement had been submitted and executed normally. This is because when the statement is planned and the planner attempts to determine the optimal query plan, the actual values of any parameters specified in the statement are unavailable. PostgreSQL collects statistics on the distribution of data in the table, and can use constant values in a statement to make guesses about the likely result of executing the statement. Since this data is unavailable when planning prepared statements with parameters, the chosen plan might be suboptimal. To examine the query plan PostgreSQL has chosen for a prepared statement, use *EXPLAIN*.

For more information on query planning and the statistics collected by PostgreSQL for that purpose, see the *ANALYZE* documentation.

You can see all available prepared statements of a session by querying the `pg_prepared_statements` system view.

## Examples

Create a prepared statement for an `INSERT` statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS
    INSERT INTO foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then execute it:

```
PREPARE usrrptplan (int) AS
    SELECT * FROM users u, logs l WHERE u.usrid=$1 AND u.usrid=l.usrid
    AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

Note that the data type of the second parameter is not specified, so it is inferred from the context in which `$2` is used.

## Compatibility

The SQL standard includes a `PREPARE` statement, but it is only for use in embedded SQL. This version of the `PREPARE` statement also uses a somewhat different syntax.

## See Also

*DEALLOCATE, EXECUTE*

# PREPARE TRANSACTION

## Name

PREPARE TRANSACTION — prepare the current transaction for two-phase commit

## Synopsis

```
PREPARE TRANSACTION transaction_id
```

## Description

PREPARE TRANSACTION prepares the current transaction for two-phase commit. After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a very high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with *COMMIT PREPARED* or *ROLLBACK PREPARED*, respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, PREPARE TRANSACTION is not unlike a ROLLBACK command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the PREPARE TRANSACTION command fails for any reason, it becomes a ROLLBACK: the current transaction is canceled.

## Parameters

*transaction\_id*

An arbitrary identifier that later identifies this transaction for COMMIT PREPARED or ROLLBACK PREPARED. The identifier must be written as a string literal, and must be less than 200 bytes long. It must not be the same as the identifier used for any currently prepared transaction.

## Notes

This command must be used inside a transaction block. Use *BEGIN* to start one.

It is not currently allowed to PREPARE a transaction that has executed any operations involving temporary tables, created any cursors WITH HOLD, or executed LISTEN or UNLISTEN. Those features are too tightly tied to the current session to be useful in a transaction to be prepared.

If the transaction modified any run-time parameters with SET (without the LOCAL option), those effects persist after PREPARE TRANSACTION, and will not be affected by any later COMMIT PREPARED

or `ROLLBACK PREPARED`. Thus, in this one respect `PREPARE TRANSACTION` acts more like `COMMIT` than `ROLLBACK`.

All currently available prepared transactions are listed in the `pg_prepared_xacts` system view.

From a performance standpoint, it is unwise to leave transactions in the prepared state for a long time: this will for instance interfere with the ability of `VACUUM` to reclaim storage. Keep in mind also that the transaction continues to hold whatever locks it held. The intended usage of the feature is that a prepared transaction will normally be committed or rolled back as soon as an external transaction manager has verified that other databases are also prepared to commit.

If you make any serious use of prepared transactions, you will probably want to increase the value of `max_prepared_transactions`, as the default setting is quite small (to avoid wasting resources for those who don't use it). It is recommendable to make it at least equal to `max_connections`, so that every session can have a prepared transaction pending.

## Examples

Prepare the current transaction for two-phase commit, using `foobar` as the transaction identifier:

```
PREPARE TRANSACTION 'foobar';
```

## See Also

*COMMIT PREPARED, ROLLBACK PREPARED*

# REASSIGN OWNED

## Name

REASSIGN OWNED — change the ownership of database objects owned by a database role

## Synopsis

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```

## Description

REASSIGN OWNED instructs the system to change the ownership of the database objects owned by one of the *old\_roles*, to *new\_role*.

## Parameters

*old\_role*

The name of a role. The ownership of all the objects in the current database owned by this role will be reassigned to *new\_role*.

*new\_role*

The name of the role that will be made the new owner of the affected objects.

## Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

The *DROP OWNED* command is an alternative that drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect the privileges granted to the *old\_roles* in objects that are not owned by them. Use *DROP OWNED* to revoke those privileges.

## Compatibility

The REASSIGN OWNED statement is a PostgreSQL extension.

## **See Also**

*DROP OWNED, DROP ROLE*

# REINDEX

## Name

REINDEX — rebuild indexes

## Synopsis

```
REINDEX { INDEX | TABLE | DATABASE | SYSTEM } name [ FORCE ]
```

## Description

REINDEX rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use REINDEX:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes can become corrupted due to software bugs or hardware failures. REINDEX provides a recovery method.
- An index has become “bloated”, that it contains many empty or nearly-empty pages. This can occur with B-tree indexes in PostgreSQL under certain uncommon access patterns. REINDEX provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages. See Section 23.2 for more information.
- You have altered a storage parameter (such as fillfactor) for an index, and wish to ensure that the change has taken full effect.
- An index build with the CONCURRENTLY option failed, leaving an “invalid” index. Such indexes are useless but it can be convenient to use REINDEX to rebuild them. Note that REINDEX will not perform a concurrent build. To build the index without interfering with production you should drop the index and reissue the CREATE INDEX CONCURRENTLY command.

## Parameters

INDEX

Recreate the specified index.

TABLE

Recreate all indexes of the specified table. If the table has a secondary “TOAST” table, that is reindexed as well.

## DATABASE

Recreate all indexes within the current database. Indexes on shared system catalogs are skipped except in stand-alone mode (see below). This form of `REINDEX` cannot be executed inside a transaction block.

## SYSTEM

Recreate all indexes on system catalogs within the current database. Indexes on user tables are not processed. Also, indexes on shared system catalogs are skipped except in stand-alone mode (see below). This form of `REINDEX` cannot be executed inside a transaction block.

*name*

The name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database, so their parameter must match the current database's name.

## FORCE

This is an obsolete option; it is ignored if specified.

## Notes

If you suspect corruption of an index on a user table, you can simply rebuild that index, or all indexes on the table, using `REINDEX INDEX` or `REINDEX TABLE`.

Things are more difficult if you need to recover from corruption of an index on a system table. In this case it's important for the system to not have used any of the suspect indexes itself. (Indeed, in this sort of scenario you might find that server processes are crashing immediately at start-up, due to reliance on the corrupted indexes.) To recover safely, the server must be started with the `-P` option, which prevents it from using indexes for system catalog lookups.

One way to do this is to shut down the server and start a single-user PostgreSQL server with the `-P` option included on its command line. Then, `REINDEX DATABASE`, `REINDEX SYSTEM`, `REINDEX TABLE`, or `REINDEX INDEX` can be issued, depending on how much you want to reconstruct. If in doubt, use `REINDEX SYSTEM` to select reconstruction of all system indexes in the database. Then quit the single-user server session and restart the regular server. See the `postgres` reference page for more information about how to interact with the single-user server interface.

Alternatively, a regular server session can be started with `-P` included in its command line options. The method for doing this varies across clients, but in all libpq-based clients, it is possible to set the `PGOPTIONS` environment variable to `-P` before starting the client. Note that while this method does not require locking out other clients, it might still be wise to prevent other users from connecting to the damaged database until repairs have been completed.

If corruption is suspected in the indexes of any of the shared system catalogs (which are `pg_authid`, `pg_auth_members`, `pg_database`, `pg_pltemplate`, `pg_shdepend`, `pg_shdescription`, and `pg_tablespace`), then a standalone server must be used to repair it. `REINDEX` will not process shared catalogs in multiuser mode.

For all indexes except the shared system catalogs, `REINDEX` is crash-safe and transaction-safe. `REINDEX` is not crash-safe for shared indexes, which is why this case is disallowed during normal operation. If a failure occurs while reindexing one of these catalogs in standalone mode, it will not be possible to restart

the regular server until the problem is rectified. (The typical symptom of a partially rebuilt shared index is “index is not a btree” errors.)

REINDEX is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. REINDEX locks out writes but not reads of the index’s parent table. It also takes an exclusive lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, DROP INDEX momentarily takes exclusive lock on the parent table, blocking both writes and reads. The subsequent CREATE INDEX locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads might be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a database requires being the owner of the database (note that the owner can therefore rebuild indexes of tables owned by other users). Of course, superusers can always reindex anything.

Prior to PostgreSQL 8.1, REINDEX DATABASE processed only system indexes, not all indexes as one would expect from the name. This has been changed to reduce the surprise factor. The old behavior is available as REINDEX SYSTEM.

Prior to PostgreSQL 7.4, REINDEX TABLE did not automatically process TOAST tables, and so those had to be reindexed by separate commands. This is still possible, but redundant.

## Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table my\_table:

```
REINDEX TABLE my_table;
```

Rebuild all indexes in a particular database, without trusting the system indexes to be valid already:

```
$ export PGOPTIONS="-P"
$ psql broken_db
...
broken_db=> REINDEX DATABASE broken_db;
broken_db=> \q
```

## Compatibility

There is no REINDEX command in the SQL standard.

# RELEASE SAVEPOINT

## Name

RELEASE SAVEPOINT — destroy a previously defined savepoint

## Synopsis

```
RELEASE [ SAVEPOINT ] savepoint_name
```

## Description

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see *ROLLBACK TO SAVEPOINT*.) Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established after the named savepoint was established.

## Parameters

*savepoint\_name*

The name of the savepoint to destroy.

## Notes

Specifying a savepoint name that was not previously defined is an error.

It is not possible to release a savepoint when the transaction is in an aborted state.

If multiple savepoints have the same name, only the one that was most recently defined is released.

## Examples

To establish and later destroy a savepoint:

```
BEGIN;  
  INSERT INTO table1 VALUES (3);  
  SAVEPOINT my_savepoint;  
  INSERT INTO table1 VALUES (4);  
  RELEASE SAVEPOINT my_savepoint;
```

`COMMIT;`

The above transaction will insert both 3 and 4.

## **Compatibility**

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but PostgreSQL allows it to be omitted.

## **See Also**

*BEGIN, COMMIT, ROLLBACK, ROLLBACK TO SAVEPOINT, SAVEPOINT*

# RESET

## Name

RESET — restore the value of a run-time parameter to the default value

## Synopsis

```
RESET configuration_parameter
RESET ALL
```

## Description

RESET restores run-time parameters to their default values. RESET is an alternative spelling for

```
SET configuration_parameter TO DEFAULT
```

Refer to *SET* for details.

The default value is defined as the value that the parameter would have had, if no SET had ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the configuration file, command-line options, or per-database or per-user default settings. This is subtly different from defining it as “the value that the parameter had at session start”, because if the value came from the configuration file, it will be reset to whatever is specified by the configuration file now. See Chapter 18 for details.

The transactional behavior of RESET is the same as SET: its effects will be undone by transaction rollback.

## Parameters

*configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in Chapter 18 and on the *SET* reference page.

ALL

Resets all settable run-time parameters to default values.

## Examples

Set the `timezone` configuration variable to its default value:

```
RESET timezone;
```

## Compatibility

RESET is a PostgreSQL extension.

## See Also

*SET, SHOW*

# REVOKE

## Name

REVOKE — remove access privileges

## Synopsis

```
REVOKE [ GRANT OPTION FOR ]
    { { SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRIGGER }
      [, ...] | ALL [ PRIVILEGES ] }
ON [ TABLE ] tablename [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { { USAGE | SELECT | UPDATE }
      [, ...] | ALL [ PRIVILEGES ] }
ON SEQUENCE sequencename [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { { CREATE | CONNECT | TEMPORARY | TEMP } [, ...] | ALL [ PRIVILEGES ] }
ON DATABASE dbname [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { EXECUTE | ALL [ PRIVILEGES ] }
ON FUNCTION funcname ( [ [ argmode ] [ argname ] argtype [, ...] ] ) [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { USAGE | ALL [ PRIVILEGES ] }
ON LANGUAGE langname [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { { CREATE | USAGE } [, ...] | ALL [ PRIVILEGES ] }
ON SCHEMA schemaname [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
    { CREATE | ALL [ PRIVILEGES ] }
ON TABLESPACE tablespacename [, ...]
FROM { [ GROUP ] rolename | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]
```

```

REVOKE [ ADMIN OPTION FOR ]
       role [, ...] FROM rolename [, ...]
       [ CASCADE | RESTRICT ]

```

## Description

The `REVOKE` command revokes previously granted privileges from one or more roles. The key word `PUBLIC` refers to the implicitly defined group of all roles.

See the description of the `GRANT` command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`. Thus, for example, revoking `SELECT` privilege from `PUBLIC` does not necessarily mean that all roles have lost `SELECT` privilege on the object: those who have it granted directly or via another role will still have it.

If `GRANT OPTION FOR` is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a user holds a privilege with grant option and has granted it to other users then the privileges held by those other users are called dependent privileges. If the privilege or the grant option held by the first user is being revoked and dependent privileges exist, those dependent privileges are also revoked if `CASCADE` is specified; if it is not, the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of users that is traceable to the user that is the subject of this `REVOKE` command. Thus, the affected users might effectively keep the privilege if it was also granted through other users.

When revoking membership in a role, `GRANT OPTION` is instead called `ADMIN OPTION`, but the behavior is similar. Note also that this form of the command does not allow the noise word `GROUP`.

## Notes

Use `psql`'s `\z` command to display the privileges granted on existing objects. See `GRANT` for information about the format.

A user can only revoke privileges that were granted directly by that user. If, for example, user A has granted a privilege with grant option to user B, and user B has in turned granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the `CASCADE` option so that the privilege is in turn revoked from user C. For another example, if both A and B have granted the same privilege to C, A can revoke his own grant but not B's grant, so C will still effectively have the privilege.

When a non-owner of an object attempts to `REVOKE` privileges on the object, the command will fail outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command will proceed, but it will revoke only those privileges for which the user has grant options. The `REVOKE ALL PRIVILEGES` forms will issue a warning message if no grant options are held, while the other forms will issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since the owner is always treated as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of `CASCADE` as stated above.

`REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the command is performed as though it were issued by the containing role that actually owns the object or holds the privileges `WITH GRANT OPTION`. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can revoke privileges on `t1` that are recorded as being granted by `g1`. This would include grants made by `u1` as well as by other members of role `g1`.

If the role executing `REVOKE` holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use `SET ROLE` to become the specific role you want to do the `REVOKE` as. Failure to do so might lead to revoking privileges other than the ones you intended, or not revoking anything at all.

## Examples

Revoke insert privilege for the public on table `films`:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from user `manuel` on view `kinds`:

```
REVOKE ALL PRIVILEGES ON kinds FROM manuel;
```

Note that this actually means “revoke all privileges that I granted”.

Revoke membership in role `admins` from user `joe`:

```
REVOKE admins FROM joe;
```

## Compatibility

The compatibility notes of the *GRANT* command apply analogously to `REVOKE`. The keyword `RESTRICT` or `CASCADE` is required according to the standard, but PostgreSQL assumes `RESTRICT` by default.

## See Also

*GRANT*

# ROLLBACK

## Name

ROLLBACK — abort the current transaction

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ]
```

## Description

ROLLBACK rolls back the current transaction and causes all the updates made by the transaction to be discarded.

## Parameters

WORK

TRANSACTION

Optional key words. They have no effect.

## Notes

Use *COMMIT* to successfully terminate a transaction.

Issuing ROLLBACK when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To abort all changes:

```
ROLLBACK;
```

## Compatibility

The SQL standard only specifies the two forms ROLLBACK and ROLLBACK WORK. Otherwise, this command is fully conforming.

## **See Also**

*BEGIN, COMMIT, ROLLBACK TO SAVEPOINT*

# ROLLBACK PREPARED

## Name

ROLLBACK PREPARED — cancel a transaction that was earlier prepared for two-phase commit

## Synopsis

```
ROLLBACK PREPARED transaction_id
```

## Description

ROLLBACK PREPARED rolls back a transaction that is in prepared state.

## Parameters

*transaction\_id*

The transaction identifier of the transaction that is to be rolled back.

## Notes

To roll back a prepared transaction, you must be either the same user that executed the transaction originally, or a superuser. But you do not have to be in the same session that executed the transaction.

This command cannot be executed inside a transaction block. The prepared transaction is rolled back immediately.

All currently available prepared transactions are listed in the `pg_prepared_xacts` system view.

## Examples

Roll back the transaction identified by the transaction identifier `foobar`:

```
ROLLBACK PREPARED 'foobar';
```

## See Also

*PREPARE TRANSACTION*, *COMMIT PREPARED*

# ROLLBACK TO SAVEPOINT

## Name

ROLLBACK TO SAVEPOINT — roll back to a savepoint

## Synopsis

```
ROLLBACK [ WORK | TRANSACTION ] TO [ SAVEPOINT ] savepoint_name
```

## Description

Roll back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

## Parameters

*savepoint\_name*

The savepoint to roll back to.

## Notes

Use *RELEASE SAVEPOINT* to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a *FETCH* command inside a savepoint that is later rolled back, the cursor position remains at the position that *FETCH* left it pointing to (that is, *FETCH* is not rolled back). Closing a cursor is not undone by rolling back, either. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using *ROLLBACK TO SAVEPOINT*, the cursor can no longer be used.

## Examples

To undo the effects of the commands executed after *my\_savepoint* was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by savepoint rollback:

```
BEGIN;

DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;

SAVEPOINT foo;

FETCH 1 FROM foo;
   ?column?
-----
          1

ROLLBACK TO SAVEPOINT foo;

FETCH 1 FROM foo;
   ?column?
-----
          2

COMMIT;
```

## Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but PostgreSQL and Oracle allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [ NO ] CHAIN` which is not currently supported by PostgreSQL. Otherwise, this command conforms to the SQL standard.

## See Also

*BEGIN, COMMIT, RELEASE SAVEPOINT, ROLLBACK, SAVEPOINT*

# SAVEPOINT

## Name

SAVEPOINT — define a new savepoint within the current transaction

## Synopsis

SAVEPOINT *savepoint\_name*

## Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

## Parameters

*savepoint\_name*

The name to give to the new savepoint.

## Notes

Use *ROLLBACK TO SAVEPOINT* to rollback to a savepoint. Use *RELEASE SAVEPOINT* to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

## Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;  
    INSERT INTO table1 VALUES (1);  
    SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (2);  
    ROLLBACK TO SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (3);  
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;  
    INSERT INTO table1 VALUES (3);  
    SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (4);  
    RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

## Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In PostgreSQL, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to `ROLLBACK TO SAVEPOINT` and `RELEASE SAVEPOINT`.) Otherwise, `SAVEPOINT` is fully SQL conforming.

# SELECT

## Name

SELECT — retrieve rows from a table or view

## Synopsis

```
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]  
      * | expression [ AS output_name ] [, ...]  
      [ FROM from_item [, ...] ]  
      [ WHERE condition ]  
      [ GROUP BY expression [, ...] ]  
      [ HAVING condition [, ...] ]  
      [ { UNION | INTERSECT | EXCEPT } [ ALL ] select ]  
      [ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...] ]  
      [ LIMIT { count | ALL } ]  
      [ OFFSET start ]  
      [ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ] [...] ]
```

where *from\_item* can be one of:

```
[ ONLY ] table_name [ * ] [ [ AS ] alias [ ( column_alias [, ...] ) ] ]  
( select ) [ AS ] alias [ ( column_alias [, ...] ) ]  
function_name ( [ argument [, ...] ] ) [ AS ] alias [ ( column_alias [, ...] | column_definition ) ]  
function_name ( [ argument [, ...] ] ) AS ( column_definition [, ...] )  
from_item [ NATURAL ] join_type from_item [ ON join_condition | USING ( join_column [, ...] ) ]
```

## Description

SELECT retrieves rows from zero or more tables. The general processing of SELECT is as follows:

1. All elements in the FROM list are computed. (Each element in the FROM list is a real or virtual table.)  
If more than one element is specified in the FROM list, they are cross-joined together. (See *FROM Clause* below.)
2. If the WHERE clause is specified, all rows that do not satisfy the condition are eliminated from the output. (See *WHERE Clause* below.)
3. If the GROUP BY clause is specified, the output is divided into groups of rows that match on one or more values. If the HAVING clause is present, it eliminates groups that do not satisfy the given condition. (See *GROUP BY Clause* and *HAVING Clause* below.)
4. The actual output rows are computed using the SELECT output expressions for each selected row. (See *SELECT List* below.)
5. Using the operators UNION, INTERSECT, and EXCEPT, the output of more than one SELECT statement can be combined to form a single result set. The UNION operator returns all rows that are in one or both of the result sets. The INTERSECT operator returns all rows that are strictly in both result sets.

The `EXCEPT` operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless `ALL` is specified. (See *UNION Clause*, *INTERSECT Clause*, and *EXCEPT Clause* below.)

6. If the `ORDER BY` clause is specified, the returned rows are sorted in the specified order. If `ORDER BY` is not given, the rows are returned in whatever order the system finds fastest to produce. (See *ORDER BY Clause* below.)
7. `DISTINCT` eliminates duplicate rows from the result. `DISTINCT ON` eliminates rows that match on all the specified expressions. `ALL` (the default) will return all candidate rows, including duplicates. (See *DISTINCT Clause* below.)
8. If the `LIMIT` or `OFFSET` clause is specified, the `SELECT` statement only returns a subset of the result rows. (See *LIMIT Clause* below.)
9. If `FOR UPDATE` or `FOR SHARE` is specified, the `SELECT` statement locks the selected rows against concurrent updates. (See *FOR UPDATE/FOR SHARE Clause* below.)

You must have `SELECT` privilege on a table to read its values. The use of `FOR UPDATE` or `FOR SHARE` requires `UPDATE` privilege as well.

## Parameters

### FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added to restrict the returned rows to a small subset of the Cartesian product.

The `FROM` clause can contain the following elements:

*table\_name*

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables (if any) are scanned. `*` can be appended to the table name to indicate that descendant tables are to be scanned, but in the current version, this is the default behavior. (In releases before 7.1, `ONLY` was the default behavior.) The default behavior can be modified by changing the `sql_inheritance` configuration option.

*alias*

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

*select*

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be

surrounded by parentheses, and an alias *must* be provided for it. A *VALUES* command can also be used here.

*function\_name*

Function calls can appear in the *FROM* clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though its output were created as a temporary table for the duration of this single *SELECT* command. An alias can also be used. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type. If the function has been defined as returning the *record* data type, then an alias or the key word *AS* must be present, followed by a column definition list in the form ( *column\_name data\_type* [, ...] ). The column definition list must match the actual number and types of columns returned by the function.

*join\_type*

One of

- [ *INNER* ] *JOIN*
- *LEFT* [ *OUTER* ] *JOIN*
- *RIGHT* [ *OUTER* ] *JOIN*
- *FULL* [ *OUTER* ] *JOIN*
- *CROSS JOIN*

For the *INNER* and *OUTER* join types, a join condition must be specified, namely exactly one of *NATURAL*, *ON join\_condition*, or *USING (join\_column [, ...])*. See below for the meaning. For *CROSS JOIN*, none of these clauses can appear.

A *JOIN* clause combines two *FROM* items. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, *JOINS* nest left-to-right. In any case *JOIN* binds more tightly than the commas separating *FROM* items.

*CROSS JOIN* and *INNER JOIN* produce a simple Cartesian product, the same result as you get from listing the two items at the top level of *FROM*, but restricted by the join condition (if any). *CROSS JOIN* is equivalent to *INNER JOIN ON (TRUE)*, that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you couldn't do with plain *FROM* and *WHERE*.

*LEFT OUTER JOIN* returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the *JOIN* clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, *RIGHT OUTER JOIN* returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a *LEFT OUTER JOIN* by switching the left and right inputs.

*FULL OUTER JOIN* returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

ON *join\_condition*

*join\_condition* is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in a join are considered to match.

USING ( *join\_column* [, ...] )

A clause of the form `USING ( a, b, ... )` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b ....` Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

NATURAL

`NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have the same names.

## WHERE Clause

The optional `WHERE` clause has the general form

`WHERE condition`

where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

## GROUP BY Clause

The optional `GROUP BY` clause has the general form

`GROUP BY expression [, ...]`

`GROUP BY` will condense into a single row all selected rows that share the same values for the grouped expressions. *expression* can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group (whereas without `GROUP BY`, an aggregate produces a single value computed across all the selected rows). When `GROUP BY` is present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions, since there would be more than one possible value to return for an ungrouped column.

## HAVING Clause

The optional `HAVING` clause has the general form

`HAVING condition`

where *condition* is the same as specified for the WHERE clause.

HAVING eliminates group rows that do not satisfy the condition. HAVING is different from WHERE: WHERE filters individual rows before the application of GROUP BY, while HAVING filters group rows created by GROUP BY. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function.

The presence of HAVING turns a query into a grouped query even if there is no GROUP BY clause. This is the same as what happens when the query contains aggregate functions but no GROUP BY clause. All the selected rows are considered to form a single group, and the SELECT list and HAVING clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the HAVING condition is true, zero rows if it is not true.

## SELECT List

The SELECT list (between the key words SELECT and FROM) specifies expressions that form the output rows of the SELECT statement. The expressions can (and usually do) refer to columns computed in the FROM clause. Using the clause AS *output\_name*, another name can be specified for an output column. This name is primarily used to label the column for display. It can also be used to refer to the column's value in ORDER BY and GROUP BY clauses, but not in the WHERE or HAVING clauses; there you must write out the expression instead.

Instead of an expression, \* can be written in the output list as a shorthand for all the columns of the selected rows. Also, one can write *table\_name.\** as a shorthand for the columns coming from just that table.

## UNION Clause

The UNION clause has this general form:

```
select_statement UNION [ ALL ] select_statement
```

*select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR UPDATE, or FOR SHARE clause. (ORDER BY and LIMIT can be attached to a subexpression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the UNION, not to its right-hand input expression.)

The UNION operator computes the set union of the rows returned by the involved SELECT statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two SELECT statements that represent the direct operands of the UNION must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of UNION does not contain any duplicate rows unless the ALL option is specified. ALL prevents elimination of duplicates. (Therefore, UNION ALL is usually significantly quicker than UNION; use ALL when you can.)

Multiple UNION operators in the same SELECT statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, FOR UPDATE and FOR SHARE cannot be specified either for a UNION result or for any input of a UNION.

## INTERSECT Clause

The `INTERSECT` clause has this general form:

```
select_statement INTERSECT [ ALL ] select_statement
```

*select\_statement* is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR UPDATE`, or `FOR SHARE` clause.

The `INTERSECT` operator computes the set intersection of the rows returned by the involved `SELECT` statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of `INTERSECT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\min(m,n)$  times in the result set.

Multiple `INTERSECT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A UNION B INTERSECT C` will be read as `A UNION (B INTERSECT C)`.

Currently, `FOR UPDATE` and `FOR SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

## EXCEPT Clause

The `EXCEPT` clause has this general form:

```
select_statement EXCEPT [ ALL ] select_statement
```

*select\_statement* is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR UPDATE`, or `FOR SHARE` clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left `SELECT` statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\max(m-n,0)$  times in the result set.

Multiple `EXCEPT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR UPDATE` and `FOR SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

## ORDER BY Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...]
```

The `ORDER BY` clause causes the result rows to be sorted according to the specified expression(s). If two rows are equal according to the leftmost expression, they are compared according to the next expression

and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

Each *expression* can be the name or ordinal number of an output column (SELECT list item), or it can be an arbitrary expression formed from input-column values.

The ordinal number refers to the ordinal (left-to-right) position of the result column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to a result column using the AS clause.

It is also possible to use arbitrary expressions in the ORDER BY clause, including columns that do not appear in the SELECT result list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an ORDER BY clause applying to the result of a UNION, INTERSECT, or EXCEPT clause can only specify an output column name or number, not an expression.

If an ORDER BY expression is a simple name that matches both a result column name and an input column name, ORDER BY will interpret it as the result column name. This is the opposite of the choice that GROUP BY will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one can add the key word ASC (ascending) or DESC (descending) after any expression in the ORDER BY clause. If not specified, ASC is assumed by default. Alternatively, a specific ordering operator name can be specified in the USING clause. An ordering operator must be a less-than or greater-than member of some B-tree operator family. ASC is usually equivalent to USING < and DESC is usually equivalent to USING >. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If NULLS LAST is specified, null values sort after all non-null values; if NULLS FIRST is specified, null values sort before all non-null values. If neither is specified, the default behavior is NULLS LAST when ASC is specified or implied, and NULLS FIRST when DESC is specified (thus, the default is to act as though nulls are larger than non-nulls). When USING is specified, the default nulls ordering depends on whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example ORDER BY x, y DESC does not mean the same thing as ORDER BY x DESC, y DESC.

Character-string data is sorted according to the locale-specific collation order that was established when the database cluster was initialized.

## DISTINCT Clause

If DISTINCT is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). ALL specifies the opposite: all rows are kept; that is the default.

DISTINCT ON ( *expression* [, ...] ) keeps only the first row of each set of rows where the given expressions evaluate to equal. The DISTINCT ON expressions are interpreted using the same rules as for ORDER BY (see above). Note that the “first row” of each set is unpredictable unless ORDER BY is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

## LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }
      OFFSET start
```

*count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, *start* rows are skipped before starting to count the *count* rows to be returned.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you might be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result *will give inconsistent results* unless you enforce a predictable result ordering with `ORDER BY`. This is not a bug; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

It is even possible for repeated executions of the same `LIMIT` query to return different subsets of the rows of a table, if there is not an `ORDER BY` to enforce selection of a deterministic subset. Again, this is not a bug; determinism of the results is simply not guaranteed in such a case.

## FOR UPDATE/FOR SHARE Clause

The `FOR UPDATE` clause has this form:

```
FOR UPDATE [ OF table_name [, ...] ] [ NOWAIT ]
```

The closely related `FOR SHARE` clause has this form:

```
FOR SHARE [ OF table_name [, ...] ] [ NOWAIT ]
```

`FOR UPDATE` causes the rows retrieved by the `SELECT` statement to be locked as though for update. This prevents them from being modified or deleted by other transactions until the current transaction ends. That is, other transactions that attempt `UPDATE`, `DELETE`, or `SELECT FOR UPDATE` of these rows will be

blocked until the current transaction ends. Also, if an `UPDATE`, `DELETE`, or `SELECT FOR UPDATE` from another transaction has already locked a selected row or rows, `SELECT FOR UPDATE` will wait for the other transaction to complete, and will then lock and return the updated row (or no row, if the row was deleted). For further discussion see Chapter 13.

To prevent the operation from waiting for other transactions to commit, use the `NOWAIT` option. `SELECT FOR UPDATE NOWAIT` reports an error, rather than waiting, if a selected row cannot be locked immediately. Note that `NOWAIT` applies only to the row-level lock(s) — the required `ROW SHARE` table-level lock is still taken in the ordinary way (see Chapter 13). You can use the `NOWAIT` option of `LOCK` if you need to acquire the table-level lock without waiting.

`FOR SHARE` behaves similarly, except that it acquires a shared rather than exclusive lock on each retrieved row. A shared lock blocks other transactions from performing `UPDATE`, `DELETE`, or `SELECT FOR UPDATE` on these rows, but it does not prevent them from performing `SELECT FOR SHARE`.

If specific tables are named in `FOR UPDATE` or `FOR SHARE`, then only rows coming from those tables are locked; any other tables used in the `SELECT` are simply read as usual. A `FOR UPDATE` or `FOR SHARE` clause without a table list affects all tables used in the command. If `FOR UPDATE` or `FOR SHARE` is applied to a view or sub-query, it affects all tables used in the view or sub-query.

Multiple `FOR UPDATE` and `FOR SHARE` clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both `FOR UPDATE` and `FOR SHARE` clauses, then it is processed as `FOR UPDATE`. Similarly, a table is processed as `NOWAIT` if that is specified in any of the clauses affecting it.

`FOR UPDATE` and `FOR SHARE` cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

### Caution

Avoid locking a row and then modifying it within a later savepoint or PL/pgSQL exception block. A subsequent rollback would cause the lock to be lost. For example:

```
BEGIN;
SELECT * FROM mytable WHERE key = 1 FOR UPDATE;
SAVEPOINT s;
UPDATE mytable SET ... WHERE key = 1;
ROLLBACK TO s;
```

After the `ROLLBACK`, the row is effectively unlocked, rather than returned to its pre-savepoint state of being locked but not modified. This hazard occurs if a row locked in the current transaction is updated or deleted, or if a shared lock is upgraded to exclusive: in all these cases, the former lock state is forgotten. If the transaction is then rolled back to a state between the original locking command and the subsequent change, the row will appear not to be locked at all. This is an implementation deficiency which will be addressed in a future release of PostgreSQL.

## Caution

It is possible for a `SELECT` command using both `LIMIT` and `FOR UPDATE/SHARE` clauses to return fewer rows than specified by `LIMIT`. This is because `LIMIT` is applied first. The command selects the specified number of rows, but might then block trying to obtain lock on one or more of them. Once the `SELECT` unblocks, the row might have been deleted or updated so that it does not meet the query `WHERE` condition anymore, in which case it will not be returned.

## Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind
FROM distributors d, films f
WHERE f.did = d.did
```

title	did	name	date_prod	kind
The Third Man	101	British Lion	1949-12-23	Drama
The African Queen	101	British Lion	1951-08-11	Romantic
...				

To sum the column `len` of all films and group the results by `kind`:

```
SELECT kind, sum(len) AS total FROM films GROUP BY kind;
```

kind	total
Action	07:34
Comedy	02:58
Drama	14:28
Musical	06:42
Romantic	04:38

To sum the column `len` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(len) AS total
FROM films
GROUP BY kind
HAVING sum(len) < interval '5 hours';
```

kind	total
Comedy	02:58

Romantic | 04:38

The following two examples are identical ways of sorting the individual results according to the contents of the second column (name):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

did	name
-----+-----	
109	20th Century Fox
110	Bavaria Atelier
101	British Lion
107	Columbia
102	Jean Luc Godard
113	Luso films
104	Mosfilm
103	Paramount
106	Toho
105	United Artists
111	Walt Disney
112	Warner Bros.
108	Westward

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter W in each table. Only distinct rows are wanted, so the key word `ALL` is omitted.

distributors:	actors:
did   name	id   name
-----+-----	-----+-----
108   Westward	1   Woody Allen
111   Walt Disney	2   Warren Beatty
112   Warner Bros.	3   Walter Matthau
...	...

```
SELECT distributors.name
  FROM distributors
 WHERE distributors.name LIKE 'W%'
UNION
SELECT actors.name
  FROM actors
 WHERE actors.name LIKE 'W%';
```

name	
-----	
Walt Disney	
Walter Matthau	
Warner Bros.	
Warren Beatty	

```
Westward
Woody Allen
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors AS $$
    SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors(111);
 did |      name
-----+-----
 111 | Walt Disney
```

```
CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS $$
    SELECT * FROM distributors WHERE did = $1;
$$ LANGUAGE SQL;
```

```
SELECT * FROM distributors_2(111) AS (f1 int, f2 text);
 f1 |      f2
-----+-----
 111 | Walt Disney
```

## Compatibility

Of course, the `SELECT` statement is compatible with the SQL standard. But there are some extensions and some missing features.

### Omitted `FROM` Clauses

PostgreSQL allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions:

```
SELECT 2+2;

?column?
-----
      4
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For example, the following query is invalid:

```
SELECT distributors.* WHERE distributors.name = 'Westward';
```

PostgreSQL releases prior to 8.1 would accept queries of this form, and add an implicit entry to the query's `FROM` clause for each table referenced by the query. This is no longer the default behavior, because it does not comply with the SQL standard, and is considered by many to be error-prone. For compatibility with applications that rely on this behavior the `add_missing_from` configuration variable can be enabled.

## The `AS` Key Word

In the SQL standard, the optional key word `AS` is just noise and can be omitted without affecting the meaning. The PostgreSQL parser requires this key word when renaming output columns because the type extensibility features lead to parsing ambiguities without it. `AS` is optional in `FROM` items, however.

## Namespace Available to `GROUP BY` and `ORDER BY`

In the SQL-92 standard, an `ORDER BY` clause can only use result column names or numbers, while a `GROUP BY` clause can only use expressions based on input column names. PostgreSQL extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). PostgreSQL also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as result-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, PostgreSQL will interpret an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

## Nonstandard Clauses

The clauses `DISTINCT ON`, `LIMIT`, and `OFFSET` are not defined in the SQL standard.

# SELECT INTO

## Name

SELECT INTO — define a new table from the results of a query

## Synopsis

```
SELECT [ ALL | DISTINCT [ ON ( expression [, ...] ) ] ]  
      * | expression [ AS output_name ] [, ...]  
INTO [ TEMPORARY | TEMP ] [ TABLE ] new_table  
[ FROM from_item [, ...] ]  
[ WHERE condition ]  
[ GROUP BY expression [, ...] ]  
[ HAVING condition [, ...] ]  
[ { UNION | INTERSECT | EXCEPT } [ ALL ] select ]  
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...] ]  
[ LIMIT { count | ALL } ]  
[ OFFSET start ]  
[ FOR { UPDATE | SHARE } [ OF table_name [, ...] ] [ NOWAIT ] [...] ]
```

## Description

SELECT INTO creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal SELECT. The new table's columns have the names and data types associated with the output columns of the SELECT.

## Parameters

TEMPORARY or TEMP

If specified, the table is created as a temporary table. Refer to *CREATE TABLE* for details.

*new\_table*

The name (optionally schema-qualified) of the table to be created.

All other parameters are described in detail under *SELECT*.

## Notes

*CREATE TABLE AS* is functionally similar to SELECT INTO. CREATE TABLE AS is the recommended syntax, since this form of SELECT INTO is not available in ECPG or PL/pgSQL, because they interpret the INTO clause differently. Furthermore, CREATE TABLE AS offers a superset of the functionality provided by SELECT INTO.

Prior to PostgreSQL 8.1, the table created by `SELECT INTO` included OIDs by default. In PostgreSQL 8.1, this is not the case — to include OIDs in the new table, the `default_with_oids` configuration variable must be enabled. Alternatively, `CREATE TABLE AS` can be used with the `WITH OIDS` clause.

## Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >= '2002-01-01';
```

## Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. This indeed is the usage found in ECPG (see Chapter 32) and PL/pgSQL (see Chapter 38). The PostgreSQL usage of `SELECT INTO` to represent table creation is historical. It is best to use `CREATE TABLE AS` for this purpose in new code.

*CREATE TABLE AS*

# SET

## Name

SET — change a run-time parameter

## Synopsis

```
SET [ SESSION | LOCAL ] configuration_parameter { TO | = } { value | 'value' | DEFAULT }  
SET [ SESSION | LOCAL ] TIME ZONE { timezone | LOCAL | DEFAULT }
```

## Description

The `SET` command changes run-time configuration parameters. Many of the run-time parameters listed in Chapter 18 can be changed on-the-fly with `SET`. (But some require superuser privileges to change, and others cannot be changed after server or session start.) `SET` only affects the value used by the current session.

If `SET` (or equivalently `SET SESSION`) is issued within a transaction that is later aborted, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

The effects of `SET` or `SET LOCAL` are also canceled by rolling back to a savepoint that is earlier than the command.

If `SET LOCAL` is used within a function that has a `SET` option for the same variable (see *CREATE FUNCTION*), the effects of the `SET LOCAL` command disappear at function exit; that is, the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while still having the convenience of using the `SET` option to save and restore the caller's value. However, a regular `SET` command overrides any surrounding function's `SET` option; its effects will persist unless rolled back.

**Note:** In PostgreSQL versions 8.0 through 8.2, the effects of a `SET LOCAL` would be canceled by releasing an earlier savepoint, or by successful exit from a PL/pgSQL exception block. This behavior has been changed because it was deemed unintuitive.

## Parameters

### SESSION

Specifies that the command takes effect for the current session. (This is the default if neither `SESSION` nor `LOCAL` appears.)

### LOCAL

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside a `BEGIN` block, since the transaction will end immediately.

### *configuration\_parameter*

Name of a settable run-time parameter. Available parameters are documented in Chapter 18 and below.

### *value*

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these, as appropriate for the particular parameter. `DEFAULT` can be written to specify resetting the parameter to its default value (that is, whatever value it would have had if no `SET` had been executed in the current session).

Besides the configuration parameters documented in Chapter 18, there are a few that can only be adjusted using the `SET` command or that have a special syntax:

### NAMES

`SET NAMES value` is an alias for `SET client_encoding TO value`.

### SEED

Sets the internal seed for the random number generator (the function `random`). Allowed values are floating-point numbers between 0 and 1, which are then multiplied by  $2^{31}-1$ .

The seed can also be set by invoking the function `setseed`:

```
SELECT setseed(value);
```

### TIME ZONE

`SET TIME ZONE value` is an alias for `SET timezone TO value`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Here are examples of valid values:

```
'PST8PDT'
```

The time zone for Berkeley, California.

```
'Europe/Rome'
```

The time zone for Italy.

```
-7
```

The time zone 7 hours west from UTC (equivalent to PDT). Positive values are east from UTC.

```
INTERVAL '-08:00' HOUR TO MINUTE
```

The time zone 8 hours west from UTC (equivalent to PST).

LOCAL  
DEFAULT

Set the time zone to your local time zone (that is, the server's default value of `timezone`; if this has not been explicitly set anywhere, it will be the zone that the server's operating system defaults to).

See Section 8.5.3 for more information about time zones.

## Notes

The function `set_config` provides equivalent functionality; see Section 9.23. Also, it is possible to UPDATE the `pg_settings` system view to perform the equivalent of SET.

## Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Set the style of date to traditional POSTGRES with “day before month” input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for Berkeley, California:

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

## Compatibility

SET TIME ZONE extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while PostgreSQL allows more flexible time-zone specifications. All other SET features are PostgreSQL extensions.

*RESET, SHOW*

# SET CONSTRAINTS

## Name

`SET CONSTRAINTS` — set constraint checking modes for the current transaction

## Synopsis

```
SET CONSTRAINTS { ALL | name [, ...] } { DEFERRED | IMMEDIATE }
```

## Description

`SET CONSTRAINTS` sets the behavior of constraint checking within the current transaction. `IMMEDIATE` constraints are checked at the end of each statement. `DEFERRED` constraints are not checked until transaction commit. Each constraint has its own `IMMEDIATE` or `DEFERRED` mode.

Upon creation, a constraint is given one of three characteristics: `DEFERRABLE INITIALLY DEFERRED`, `DEFERRABLE INITIALLY IMMEDIATE`, or `NOT DEFERRABLE`. The third class is always `IMMEDIATE` and is not affected by the `SET CONSTRAINTS` command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by `SET CONSTRAINTS`.

`SET CONSTRAINTS` with a list of constraint names changes the mode of just those constraints (which must all be deferrable). The current schema search path is used to find the first matching name if no schema name is specified. `SET CONSTRAINTS ALL` changes the mode of all deferrable constraints.

When `SET CONSTRAINTS` changes the mode of a constraint from `DEFERRED` to `IMMEDIATE`, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the `SET CONSTRAINTS` command. If any such constraint is violated, the `SET CONSTRAINTS` fails (and does not change the constraint mode). Thus, `SET CONSTRAINTS` can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only foreign key constraints are affected by this setting. Check and unique constraints are always effectively not deferrable. Triggers that are declared as “constraint triggers” are also affected.

## Notes

This command only alters the behavior of constraints within the current transaction. Thus, if you execute this command outside of a transaction block (`BEGIN/COMMIT` pair), it will not appear to have any effect.

## Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in PostgreSQL, it only applies to foreign-key constraints.

# SET ROLE

## Name

`SET ROLE` — set the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] ROLE rolename
SET [ SESSION | LOCAL ] ROLE NONE
RESET ROLE
```

## Description

This command sets the current user identifier of the current SQL session to be *rolename*. The role name can be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified *rolename* must be a role that the current session user is a member of. (If the session user is a superuser, any role can be selected.)

The `SESSION` and `LOCAL` modifiers act the same as for the regular `SET` command.

The `NONE` and `RESET` forms reset the current user identifier to be the current session user identifier. These forms can be executed by any user.

## Notes

Using this command, it is possible to either add privileges or restrict one's privileges. If the session user role has the `INHERITS` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the `NOINHERITS` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, she loses her superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

`SET ROLE` cannot be used within a `SECURITY DEFINER` function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```

 session_user | current_user
-----+-----
peter        | peter

```

```
SET ROLE 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```

 session_user | current_user
-----+-----
peter        | paul

```

## Compatibility

PostgreSQL allows identifier syntax ("`rolename`"), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The `SESSION` and `LOCAL` modifiers are a PostgreSQL extension, as is the `RESET` syntax.

## See Also

*SET SESSION AUTHORIZATION*

# SET SESSION AUTHORIZATION

## Name

SET SESSION AUTHORIZATION — set the session user identifier and the current user identifier of the current session

## Synopsis

```
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION username
SET [ SESSION | LOCAL ] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

## Description

This command sets the session user identifier and the current user identifier of the current SQL session to be *username*. The user name can be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session user identifier is initially set to be the (possibly authenticated) user name provided by the client. The current user identifier is normally equal to the session user identifier, but might change temporarily in the context of `SECURITY DEFINER` functions and similar mechanisms; it can also be changed by `SET ROLE`. The current user identifier is relevant for permission checking.

The session user identifier can be changed only if the initial session user (the *authenticated user*) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `SESSION` and `LOCAL` modifiers act the same as for the regular `SET` command.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms can be executed by any user.

## Notes

SET SESSION AUTHORIZATION cannot be used within a SECURITY DEFINER function.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
```

```
 session_user | current_user
-----+-----
peter        | peter
```

```
SET SESSION AUTHORIZATION 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
```

```

 session_user | current_user
-----+-----
paul          | paul

```

## Compatibility

The SQL standard allows some other expressions to appear in place of the literal *username*, but these options are not important in practice. PostgreSQL allows identifier syntax ("*username*"), which SQL does not. SQL does not allow this command during a transaction; PostgreSQL does not make this restriction because there is no reason to. The `SESSION` and `LOCAL` modifiers are a PostgreSQL extension, as is the `RESET` syntax.

The privileges necessary to execute this command are left implementation-defined by the standard.

## See Also

*SET ROLE*

# SET TRANSACTION

## Name

SET TRANSACTION — set the characteristics of the current transaction

## Synopsis

```
SET TRANSACTION transaction_mode [, ...]
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode [, ...]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED }
READ WRITE | READ ONLY
```

## Description

The SET TRANSACTION command sets the characteristics of the current transaction. It has no effect on any subsequent transactions. SET SESSION CHARACTERISTICS sets the default transaction characteristics for subsequent transactions of a session. These defaults can be overridden by SET TRANSACTION for an individual transaction.

The available transaction characteristics are the transaction isolation level and the transaction access mode (read/write or read-only).

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently:

READ COMMITTED

A statement can only see rows committed before it began. This is the default.

SERIALIZABLE

All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

The SQL standard defines two additional levels, READ UNCOMMITTED and REPEATABLE READ. In PostgreSQL READ UNCOMMITTED is treated as READ COMMITTED, while REPEATABLE READ is treated as SERIALIZABLE.

The transaction isolation level cannot be changed after the first query or data-modification statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) of a transaction has been executed. See Chapter 13 for more information about transaction isolation and concurrency control.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: INSERT, UPDATE, DELETE, and COPY FROM if the table they would write to is not a temporary table; all CREATE, ALTER, and DROP commands; COMMENT, GRANT, REVOKE, TRUNCATE; and EXPLAIN ANALYZE and

EXECUTE if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

## Notes

If SET TRANSACTION is executed without a prior START TRANSACTION or BEGIN, it will appear to have no effect, since the transaction will immediately end.

It is possible to dispense with SET TRANSACTION by instead specifying the desired *transaction\_modes* in BEGIN or START TRANSACTION.

The session default transaction modes can also be set by setting the configuration parameters `default_transaction_isolation` and `default_transaction_read_only`. (In fact SET SESSION CHARACTERISTICS is just a verbose equivalent for setting these variables with SET.) This means the defaults can be set in the configuration file, via ALTER DATABASE, etc. Consult Chapter 18 for more information.

## Compatibility

Both commands are defined in the SQL standard. `SERIALIZABLE` is the default transaction isolation level in the standard. In PostgreSQL the default is ordinarily `READ COMMITTED`, but you can change it as mentioned above. Because of lack of predicate locking, the `SERIALIZABLE` level is not truly serializable. See Chapter 13 for details.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the PostgreSQL server.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons PostgreSQL allows the commas to be omitted.

# SHOW

## Name

SHOW — show the value of a run-time parameter

## Synopsis

```
SHOW name
SHOW ALL
```

## Description

SHOW will display the current setting of run-time parameters. These variables can be set using the SET statement, by editing the `postgresql.conf` configuration file, through the `PGOPTIONS` environmental variable (when using libpq or a libpq-based application), or through command-line flags when starting the `postgres` server. See Chapter 18 for details.

## Parameters

*name*

The name of a run-time parameter. Available parameters are documented in Chapter 18 and on the SET reference page. In addition, there are a few parameters that can be shown but not set:

SERVER\_VERSION

Shows the server's version number.

SERVER\_ENCODING

Shows the server-side character set encoding. At present, this parameter can be shown but not set, because the encoding is determined at database creation time.

LC\_COLLATE

Shows the database's locale setting for collation (text ordering). At present, this parameter can be shown but not set, because the setting is determined at `initdb` time.

LC\_CTYPE

Shows the database's locale setting for character classification. At present, this parameter can be shown but not set, because the setting is determined at `initdb` time.

IS\_SUPERUSER

True if the current role has superuser privileges.

ALL

Show the values of all configuration parameters, with descriptions.

Notes

The function `current_setting` produces equivalent output; see Section 9.23. Also, the `pg_settings` system view produces the same information.

Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
DateStyle
-----
ISO, MDY
(1 row)
```

Show the current setting of the parameter `geqo`:

```
SHOW geqo;
geqo
-----
on
(1 row)
```

Show all settings:

```
SHOW ALL;
name | setting |
-----+-----+
add_missing_from | off | Automatically adds missing
allow_system_table_mods | off | Allows modifications of
.
.
.
work_mem | 1024 | Sets the maximum memory
zero_damaged_pages | off | Continues processing pas
(146 rows)
```

## Compatibility

The *SHOW* command is a PostgreSQL extension.

## See Also

*SET*, *RESET*

# START TRANSACTION

## Name

START TRANSACTION — start a transaction block

## Synopsis

```
START TRANSACTION [ transaction_mode [, ...] ]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED }  
READ WRITE | READ ONLY
```

## Description

This command begins a new transaction block. If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if *SET TRANSACTION* was executed. This is the same as the *BEGIN* command.

## Parameters

Refer to *SET TRANSACTION* for information on the meaning of the parameters to this statement.

## Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. PostgreSQL’s behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called “autocommit”. Other relational database systems might offer an autocommit feature as a convenience.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons PostgreSQL allows the commas to be omitted.

See also the compatibility section of *SET TRANSACTION*.

## See Also

*BEGIN*, *COMMIT*, *ROLLBACK*, *SAVEPOINT*, *SET TRANSACTION*

# TRUNCATE

## Name

TRUNCATE — empty a table or set of tables

## Synopsis

```
TRUNCATE [ TABLE ] name [, ...] [ CASCADE | RESTRICT ]
```

## Description

TRUNCATE quickly removes all rows from a set of tables. It has the same effect as an unqualified DELETE on each table, but since it does not actually scan the tables it is faster. Furthermore, it reclaims disk space immediately, rather than requiring a subsequent VACUUM operation. This is most useful on large tables.

## Parameters

*name*

The name (optionally schema-qualified) of a table to be truncated.

CASCADE

Automatically truncate all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to CASCADE.

RESTRICT

Refuse to truncate if any of the tables have foreign-key references from tables that are not to be truncated. This is the default.

## Notes

Only the owner of a table can TRUNCATE it.

TRUNCATE cannot be used on a table that has foreign-key references from other tables, unless all such tables are also truncated in the same command. Checking validity in such cases would require table scans, and the whole point is not to do one. The CASCADE option can be used to automatically include all dependent tables — but be very careful when using this option, or else you might lose data you did not intend to!

TRUNCATE will not run any ON DELETE triggers that might exist for the tables.

## Warning

`TRUNCATE` is not MVCC-safe (see Chapter 13 for general information about MVCC). After truncation, the table will appear empty to all concurrent transactions, even if they are using a snapshot taken before the truncation occurred. This will only be an issue for a transaction that did not access the truncated table before the truncation happened — any transaction that has done so would hold at least an `ACCESS SHARE` lock, which would block `TRUNCATE` until that transaction completes. So truncation will not cause any apparent inconsistency in the table contents for successive queries on the same table, but it could cause visible inconsistency between the contents of the truncated table and other tables in the database.

`TRUNCATE` is transaction-safe, however: the truncation will be safely rolled back if the surrounding transaction does not commit.

## Examples

Truncate the tables `bigtable` and `fattable`:

```
TRUNCATE bigtable, fattable;
```

Truncate the table `othertable`, and cascade to any tables that reference `othertable` via foreign-key constraints:

```
TRUNCATE othertable CASCADE;
```

## Compatibility

There is no `TRUNCATE` command in the SQL standard.

# UNLISTEN

## Name

UNLISTEN — stop listening for a notification

## Synopsis

```
UNLISTEN { name | * }
```

## Description

UNLISTEN is used to remove an existing registration for NOTIFY events. UNLISTEN cancels any existing registration of the current PostgreSQL session as a listener on the notification *name*. The special wildcard \* cancels all listener registrations for the current session.

*NOTIFY* contains a more extensive discussion of the use of LISTEN and NOTIFY.

## Parameters

*name*

Name of a notification (any identifier).

\*

All current listen registrations for this session are cleared.

## Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, UNLISTEN \* is automatically executed.

## Examples

To make a registration:

```
LISTEN virtual;
```

```
NOTIFY virtual;
```

```
Asynchronous notification "virtual" received from server process with PID 8448.
```

Once UNLISTEN has been executed, further NOTIFY commands will be ignored:

```
UNLISTEN virtual;  
NOTIFY virtual;  
-- no NOTIFY event is received
```

## Compatibility

There is no `UNLISTEN` command in the SQL standard.

## See Also

*LISTEN*, *NOTIFY*

# UPDATE

## Name

UPDATE — update rows of a table

## Synopsis

```
UPDATE [ ONLY ] table [ [ AS ] alias ]
    SET { column = { expression | DEFAULT } |
        ( column [, ...] ) = ( { expression | DEFAULT } [, ...] ) } [, ...]
[ FROM fromlist ]
[ WHERE condition | WHERE CURRENT OF cursor_name ]
[ RETURNING * | output_expression [ AS output_name ] [, ...] ]
```

## Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

By default, UPDATE will update rows in the specified table and all its subtables. If you wish to only update the specific table mentioned, you must use the ONLY clause.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

The optional RETURNING clause causes UPDATE to compute and return value(s) based on each row actually updated. Any expression using the table's columns, and/or columns of other tables mentioned in FROM, can be computed. The new (post-update) values of the table's columns are used. The syntax of the RETURNING list is identical to that of the output list of SELECT.

You must have the UPDATE privilege on the table to update it, as well as the SELECT privilege to any table whose values are read in the *expressions* or *condition*.

## Parameters

*table*

The name (optionally schema-qualified) of the table to update.

*alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given UPDATE foo AS f, the remainder of the UPDATE statement must refer to this table as f not foo.

*column*

The name of a column in *table*. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column — for example, `UPDATE tab SET tab.col = 1` is invalid.

*expression*

An expression to assign to the column. The expression can use the old values of this and other columns in the table.

## DEFAULT

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

*fromlist*

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition and the update expressions. This is similar to the list of tables that can be specified in the *FROM Clause* of a `SELECT` statement. Note that the target table must not appear in the *fromlist*, unless you intend a self-join (in which case it must appear with an alias in the *fromlist*).

*condition*

An expression that returns a value of type `boolean`. Only rows for which this expression returns `true` will be updated.

*cursor\_name*

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from this cursor. The cursor must be a simple (non-join, non-aggregate) query on the `UPDATE`'s target table. Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition.

*output\_expression*

An expression to be computed and returned by the `UPDATE` command after each row is updated. The expression can use any column names of the *table* or table(s) listed in `FROM`. Write `*` to return all columns.

*output\_name*

A name to use for a returned column.

## Outputs

On successful completion, an `UPDATE` command returns a command tag of the form

```
UPDATE count
```

The *count* is the number of rows updated. If *count* is 0, no rows matched the *condition* (this is not considered an error).

If the `UPDATE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) updated by the command.

## Notes

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the *fromlist*, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row shouldn't join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

## Examples

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films`:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table `weather`:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
  WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Perform the same operation and return the updated entries:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi = temp_lo+15, prcp = DEFAULT
  WHERE city = 'San Francisco' AND date = '2003-07-03'
  RETURNING temp_lo, temp_hi, prcp;
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1, temp_lo+15, DEFAULT)
  WHERE city = 'San Francisco' AND date = '2003-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax:

```
UPDATE employees SET sales_count = sales_count + 1 FROM accounts
  WHERE accounts.name = 'Acme Corporation'
  AND employees.id = accounts.sales_person;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
  (SELECT sales_person FROM accounts WHERE name = 'Acme Corporation');
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints:

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

Change the `kind` column of the table `films` in the row on which the cursor `c_films` is currently positioned:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

## Compatibility

This command conforms to the SQL standard, except that the `FROM` and `RETURNING` clauses are PostgreSQL extensions.

According to the standard, the column-list syntax should allow a list of columns to be assigned from a single row-valued expression, such as a sub-select:

```
UPDATE accounts SET (contact_last_name, contact_first_name) =
    (SELECT last_name, first_name FROM salesmen
     WHERE salesmen.id = accounts.sales_id);
```

This is not currently implemented — the source must be a list of independent expressions.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how PostgreSQL interprets `FROM`. Be careful when porting applications that use this extension.

# VACUUM

## Name

VACUUM — garbage-collect and optionally analyze a database

## Synopsis

```
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] [ table ]
VACUUM [ FULL ] [ FREEZE ] [ VERBOSE ] ANALYZE [ table [ (column [, ...] ) ] ]
```

## Description

VACUUM reclaims storage occupied by dead tuples. In normal PostgreSQL operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present until a VACUUM is done. Therefore it's necessary to do VACUUM periodically, especially on frequently-updated tables.

With no parameter, VACUUM processes every table in the current database. With a parameter, VACUUM processes only that table.

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See ANALYZE for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. VACUUM FULL does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. This form is much slower and requires an exclusive lock on each table while it is being processed.

## Parameters

FULL

Selects “full” vacuum, which can reclaim more space, but takes much longer and exclusively locks the table.

FREEZE

Selects aggressive “freezing” of tuples. Specifying FREEZE is equivalent to performing VACUUM with the vacuum\_freeze\_min\_age parameter set to zero. The FREEZE option is deprecated and will be removed in a future release; set the parameter instead.

VERBOSE

Prints a detailed vacuum activity report for each table. Can be used to help determine appropriate settings for max\_fsm\_pages, max\_fsm\_relations, and default\_statistics\_target.

ANALYZE

Updates statistics used by the planner to determine the most efficient way to execute a query.

*table*

The name (optionally schema-qualified) of a specific table to vacuum. Defaults to all tables in the current database.

*column*

The name of a specific column to analyze. Defaults to all columns.

## Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

## Notes

`VACUUM` cannot be executed inside a transaction block.

We recommend that active production databases be vacuumed frequently (at least nightly), in order to remove dead rows. After adding or deleting a large number of rows, it might be a good idea to issue a `VACUUM ANALYZE` command for the affected table. This will update the system catalogs with the results of all recent changes, and allow the PostgreSQL query planner to make better choices in planning queries.

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` will usually shrink the table more than a plain `VACUUM` would. The `FULL` option does not shrink indexes; a periodic `REINDEX` is still recommended. In fact, it is often faster to drop all indexes, `VACUUM FULL`, and recreate the indexes.

`VACUUM` causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based vacuum delay feature. See Section 18.4.4 for details.

PostgreSQL includes an “autovacuum” facility which can automate routine vacuum maintenance. For more information about automatic and manual vacuuming, see Section 23.1.

## Examples

The following is an example from running `VACUUM` on a table in the regression database:

```
regression=# VACUUM VERBOSE ANALYZE onek;
INFO:  vacuuming "public.onek"
INFO:  index "onek_unique1" now contains 1000 tuples in 14 pages
DETAIL:  3000 index tuples were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.01s/0.08u sec elapsed 0.18 sec.
INFO:  index "onek_unique2" now contains 1000 tuples in 16 pages
DETAIL:  3000 index tuples were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.00s/0.07u sec elapsed 0.23 sec.
```

```
INFO:  index "onek_hundred" now contains 1000 tuples in 13 pages
DETAIL:  3000 index tuples were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.01s/0.08u sec elapsed 0.17 sec.
INFO:  index "onek_stringul" now contains 1000 tuples in 48 pages
DETAIL:  3000 index tuples were removed.
0 index pages have been deleted, 0 are currently reusable.
CPU 0.01s/0.09u sec elapsed 0.59 sec.
INFO:  "onek": removed 3000 tuples in 108 pages
DETAIL:  CPU 0.01s/0.06u sec elapsed 0.07 sec.
INFO:  "onek": found 3000 removable, 1000 nonremovable tuples in 143 pages
DETAIL:  0 dead tuples cannot be removed yet.
There were 0 unused item pointers.
0 pages are entirely empty.
CPU 0.07s/0.39u sec elapsed 1.56 sec.
INFO:  analyzing "public.onek"
INFO:  "onek": 36 pages, 1000 rows sampled, 1000 estimated total rows
VACUUM
```

## Compatibility

There is no VACUUM statement in the SQL standard.

*vacuumdb, Cost-Based Vacuum Delay, The Auto-Vacuum Daemon*

# VALUES

## Name

VALUES — compute a set of rows

## Synopsis

```
VALUES ( expression [, ...] ) [, ...]  
    [ ORDER BY sort_expression [ ASC | DESC | USING operator ] [, ...] ]  
    [ LIMIT { count | ALL } ]  
    [ OFFSET start ]
```

## Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a “constant table” within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table’s columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION (see Section 10.5).

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT, and OFFSET clauses with a VALUES command.

## Parameters

*expression*

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an *expression* can be replaced by DEFAULT to indicate that the destination column’s default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

*sort\_expression*

An expression or integer constant indicating how to sort the result rows. This expression can refer to the columns of the VALUES result as column1, column2, etc. For more details see *ORDER BY Clause*.

*operator*

A sorting operator. For details see *ORDER BY Clause*.

*count*

The maximum number of rows to return. For details see *LIMIT Clause*.

*start*

The number of rows to skip before starting to return rows. For details see *LIMIT Clause*.

## Notes

VALUES lists with very large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

## Examples

A bare VALUES command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It's effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82 minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.*
FROM films f, (VALUES('MGM', 'Horror'), ('UA', 'Sci-Fi')) AS t (studio, kind)
WHERE f.studio = t.studio AND f.kind = t.kind;

UPDATE employees SET salary = salary * v.increase
FROM (VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno, target, increase)
WHERE employees.depno = v.depno AND employees.sales >= v.target;
```

Note that an `AS` clause is required when `VALUES` is used in a `FROM` clause, just as is true for `SELECT`. It is not required that the `AS` clause specify names for all the columns, but it's good practice to do so. (The default column names for `VALUES` are `column1`, `column2`, etc in PostgreSQL, but these names might be different in other database systems.)

When `VALUES` is used in `INSERT`, the values are all automatically coerced to the data type of the corresponding destination column. When it's used in other contexts, it might be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines
WHERE ip_address IN (VALUES('192.168.0.1'::inet), ('192.168.0.10'), ('192.168.1.43'));
```

**Tip:** For simple `IN` tests, it's better to rely on the list-of-scalars form of `IN` than to write a `VALUES` query as shown above. The list of scalars method requires less writing and is often more efficient.

## Compatibility

`VALUES` conforms to the SQL standard, except that `LIMIT` and `OFFSET` are PostgreSQL extensions.

## See Also

*INSERT*, *SELECT*

## II. PostgreSQL Client Applications

This part contains reference information for PostgreSQL client applications and utilities. Not all of these commands are of general utility, some might require special privileges. The common feature of these applications is that they can be run on any host, independent of where the database server resides.

# clusterdb

## Name

clusterdb — cluster a PostgreSQL database

## Synopsis

```
clusterdb [connection-option...] [--table | -t table] [dbname]  
clusterdb [connection-option...] [--all | -a]
```

## Description

clusterdb is a utility for recluster tables in a PostgreSQL database. It finds tables that have previously been clustered, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

clusterdb is a wrapper around the SQL command *CLUSTER*. There is no effective difference between clustering databases via this utility and via other methods for accessing the server.

## Options

clusterdb accepts the following command-line arguments:

-a  
--all

Cluster all databases.

[-d] *dbname*  
[--dbname] *dbname*

Specifies the name of the database to be clustered. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e  
--echo

Echo the commands that clusterdb generates and sends to the server.

-q  
--quiet

Do not display progress messages.

```
-t table
--table table
```

Cluster *table* only.

clusterdb also accepts the following command-line arguments for connection parameters:

```
-h host
--host host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as.

```
-W
--password
```

Force clusterdb to prompt for a password before connecting to a database.

This option is never essential, since clusterdb will automatically prompt for a password if the server demands password authentication. However, clusterdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *CLUSTER* and *psql* for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To cluster the database `test`:

```
$ clusterdb test
```

To cluster a single table `foo` in a database named `xyzzzy`:

```
$ clusterdb --table foo xyzzzy
```

## See Also

*CLUSTER*

# createdb

## Name

`createdb` — create a new PostgreSQL database

## Synopsis

```
createdb [option...] [dbname] [description]
```

## Description

`createdb` creates a new PostgreSQL database.

Normally, the database user who executes this command becomes the owner of the new database. However a different owner can be specified via the `-O` option, if the executing user has appropriate privileges.

`createdb` is a wrapper around the SQL command *CREATE DATABASE*. There is no effective difference between creating databases via this utility and via other methods for accessing the server.

## Options

`createdb` accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be created. The name must be unique among all PostgreSQL databases in this cluster. The default is to create a database with the same name as the current system user.

*description*

Specifies a comment to be associated with the newly created database.

`-D tablespace`

`--tablespace tablespace`

Specifies the default tablespace for the database.

`-e`

`--echo`

Echo the commands that `createdb` generates and sends to the server.

`-E encoding`

`--encoding encoding`

Specifies the character encoding scheme to be used in this database. The character sets supported by the PostgreSQL server are described in Section 22.2.1.

```
-O owner
--owner owner
```

Specifies the database user who will own the new database.

```
-T template
--template template
```

Specifies the template database from which to build this database.

The options `-D`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command *CREATE DATABASE*; see there for more information about them.

createdb also accepts the following command-line arguments for connection parameters:

```
-h host
--host host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as.

```
-W
--password
```

Force createdb to prompt for a password before connecting to a database.

This option is never essential, since createdb will automatically prompt for a password if the server demands password authentication. However, createdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

PGDATABASE

If set, the name of the database to create, unless overridden on the command line.

PGHOST

PGPORT

PGUSER

Default connection parameters. PGUSER also determines the name of the database to create, if it is not specified on the command line or by PGDATABASE.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *CREATE DATABASE* and *psql* for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To create the database `demo` using the default database server:

```
$ createdb demo
```

To create the database `demo` using the server on host `eden`, port 5000, using the `LATIN1` encoding scheme with a look at the underlying command:

```
$ createdb -p 5000 -h eden -E LATIN1 -e demo  
CREATE DATABASE demo ENCODING 'LATIN1';
```

## See Also

`dropdb`, *CREATE DATABASE*

# createlang

## Name

createlang — define a new PostgreSQL procedural language

## Synopsis

```
createlang [connection-option...] langname [dbname]
createlang [connection-option...] --list | -l dbname
```

## Description

createlang is a utility for adding a new programming language to a PostgreSQL database. createlang is just a wrapper around the *CREATE LANGUAGE* command.

## Options

createlang accepts the following command-line arguments:

*langname*

Specifies the name of the procedural programming language to be defined.

`[-d] dbname`

`--dbname dbname`

Specifies to which database the language should be added. The default is to use the database with the same name as the current system user.

`-e`

`--echo`

Display SQL commands as they are executed.

`-l`

`--list`

Show a list of already installed languages in the target database.

createlang also accepts the following command-line arguments for connection parameters:

`-h host`

`--host host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username username`

User name to connect as.

`-W`  
`--password`

Force createlang to prompt for a password before connecting to a database.

This option is never essential, since createlang will automatically prompt for a password if the server demands password authentication. However, createlang will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

Most error messages are self-explanatory. If not, run createlang with the `--echo` option and see under the respective SQL command for details. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

Use droplang to remove a language.

## Examples

To install the language `pltcl` into the database `template1`:

```
$ createlang pltcl template1
```

Note that installing the language into `template1` will cause it to be automatically installed into subsequently-created databases as well.

## See Also

`droplang`, *CREATE LANGUAGE*

# createuser

## Name

`createuser` — define a new PostgreSQL user account

## Synopsis

```
createuser [option...] [username]
```

## Description

`createuser` creates a new PostgreSQL user (or more precisely, a role). Only superusers and users with `CREATEROLE` privilege can create new users, so `createuser` must be invoked by someone who can connect as a superuser or a user with `CREATEROLE` privilege.

If you wish to create a new superuser, you must connect as a superuser, not merely with `CREATEROLE` privilege. Being a superuser implies the ability to bypass all access permission checks within the database, so superuserdom should not be granted lightly.

`createuser` is a wrapper around the SQL command *CREATE ROLE*. There is no effective difference between creating users via this utility and via other methods for accessing the server.

## Options

`createuser` accepts the following command-line arguments:

*username*

Specifies the name of the PostgreSQL user to be created. This name must be different from all existing roles in this PostgreSQL installation.

`-s`

`--superuser`

The new user will be a superuser.

`-S`

`--no-superuser`

The new user will not be a superuser. This is the default.

`-d`

`--createdb`

The new user will be allowed to create databases.

-D

--no-createdb

The new user will not be allowed to create databases. This is the default.

-r

--createrole

The new user will be allowed to create new roles (that is, this user will have `CREATEROLE` privilege).

-R

--no-createrole

The new user will not be allowed to create new roles. This is the default.

-l

--login

The new user will be allowed to log in (that is, the user name can be used as the initial session user identifier). This is the default.

-L

--no-login

The new user will not be allowed to log in. (A role without login privilege is still useful as a means of managing database permissions.)

-i

--inherit

The new role will automatically inherit privileges of roles it is a member of. This is the default.

-I

--no-inherit

The new role will not automatically inherit privileges of roles it is a member of.

-c *number*

--connection-limit *number*

Set a maximum number of connections for the new user. The default is to set no limit.

-P

--pwprompt

If given, createuser will issue a prompt for the password of the new user. This is not necessary if you do not plan on using password authentication.

-E

--encrypted

Encrypts the user's password stored in the database. If not specified, the default password behavior is used.

-N

--unencrypted

Does not encrypt the user's password stored in the database. If not specified, the default password behavior is used.

```
-e
--echo
```

Echo the commands that createuser generates and sends to the server.

You will be prompted for a name and other missing information if it is not specified on the command line. createuser also accepts the following command-line arguments for connection parameters:

```
-h host
--host host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as (not the user name to create).

```
-W
--password
```

Force createuser to prompt for a password (for connecting to the server, not for the password of the new user).

This option is never essential, since createuser will automatically prompt for a password if the server demands password authentication. However, createuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *CREATE ROLE* and *psql* for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the *libpq* front-end library will apply.

## Examples

To create a user *joe* on the default database server:

```
$ createuser joe
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
```

To create the same user *joe* using the server on host *eden*, port 5000, avoiding the prompts and taking a look at the underlying command:

```
$ createuser -h eden -p 5000 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT LOGIN;
```

To create the user *joe* as a superuser, and assign a password immediately:

```
$ createuser -P -s -e joe
Enter password for new role: xyzzzy
Enter it again: xyzzzy
CREATE ROLE joe PASSWORD 'md5b5f5ba1a423792b526f799ae4eb3d59e' SUPERUSER CREATEDB CREATEROLE INHERIT
```

In the above example, the new password isn't actually echoed when typed, but we show what was typed for clarity. As you see, the password is encrypted before it is sent to the client. If the option *--unencrypted* is used, the password *will* appear in the echoed command (and possibly also in the server log and elsewhere), so you don't want to use *-e* in that case, if anyone else can see your screen.

## See Also

dropuser, *CREATE ROLE*

# dropdb

## Name

dropdb — remove a PostgreSQL database

## Synopsis

dropdb [*option...*] *dbname*

## Description

dropdb destroys an existing PostgreSQL database. The user who executes this command must be a database superuser or the owner of the database.

dropdb is a wrapper around the SQL command *DROP DATABASE*. There is no effective difference between dropping databases via this utility and via other methods for accessing the server.

## Options

dropdb accepts the following command-line arguments:

*dbname*

Specifies the name of the database to be removed.

`-e`

`--echo`

Echo the commands that dropdb generates and sends to the server.

`-i`

`--interactive`

Issues a verification prompt before doing anything destructive.

dropdb also accepts the following command-line arguments for connection parameters:

`-h` *host*

`--host` *host*

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as.

```
-W
--password
```

Force dropdb to prompt for a password before connecting to a database.

This option is never essential, since dropdb will automatically prompt for a password if the server demands password authentication. However, dropdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *DROP DATABASE* and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To destroy the database `demo` on the default database server:

```
$ dropdb demo
```

To destroy the database `demo` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropdb -p 5000 -h eden -i -e demo
```

```
Database "demo" will be permanently deleted.  
Are you sure? (y/n) y  
DROP DATABASE demo;
```

## See Also

createdb, *DROP DATABASE*

# droplang

## Name

droplang — remove a PostgreSQL procedural language

## Synopsis

```
droplang [connection-option...] langname [dbname]  
droplang [connection-option...] --list | -l dbname
```

## Description

droplang is a utility for removing an existing programming language from a PostgreSQL database. droplang can drop any procedural language, even those not supplied by the PostgreSQL distribution.

Although backend programming languages can be removed directly using several SQL commands, it is recommended to use droplang because it performs a number of checks and is much easier to use. See *DROP LANGUAGE* for more.

## Options

droplang accepts the following command line arguments:

*langname*

Specifies the name of the backend programming language to be removed.

`[-d] dbname`

`[--dbname] dbname`

Specifies from which database the language should be removed. The default is to use the database with the same name as the current system user.

`-e`

`--echo`

Display SQL commands as they are executed.

`-l`

`--list`

Show a list of already installed languages in the target database.

droplang also accepts the following command line arguments for connection parameters:

```
-h host
--host host
```

Specifies the host name of the machine on which the server is running. If host begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the Internet TCP/IP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as.

```
-W
--password
```

Force droplang to prompt for a password before connecting to a database.

This option is never essential, since droplang will automatically prompt for a password if the server demands password authentication. However, droplang will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

Most error messages are self-explanatory. If not, run droplang with the `--echo` option and see under the respective SQL command for details. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

Use createlang to add a language.

## Examples

To remove the language `pltcl`:

```
$ droplang pltcl dbname
```

## See Also

`createlang`, *DROP LANGUAGE*

# dropuser

## Name

`dropuser` — remove a PostgreSQL user account

## Synopsis

```
dropuser [option...] [username]
```

## Description

`dropuser` removes an existing PostgreSQL user. Only superusers and users with the `CREATEROLE` privilege can remove PostgreSQL users. (To remove a superuser, you must yourself be a superuser.)

`dropuser` is a wrapper around the SQL command *DROP ROLE*. There is no effective difference between dropping users via this utility and via other methods for accessing the server.

## Options

`dropuser` accepts the following command-line arguments:

*username*

Specifies the name of the PostgreSQL user to be removed. You will be prompted for a name if none is specified on the command line.

`-e`

`--echo`

Echo the commands that `dropuser` generates and sends to the server.

`-i`

`--interactive`

Prompt for confirmation before actually removing the user.

`dropuser` also accepts the following command-line arguments for connection parameters:

`-h host`

`--host host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as (not the user name to drop).

```
-W
--password
```

Force dropuser to prompt for a password before connecting to a database.

This option is never essential, since dropuser will automatically prompt for a password if the server demands password authentication. However, dropuser will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *DROP ROLE* and *psql* for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Examples

To remove user `joe` from the default database server:

```
$ dropuser joe
```

To remove user `joe` using the server on host `eden`, port 5000, with verification and a peek at the underlying command:

```
$ dropuser -p 5000 -h eden -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE joe;
```

createuser, *DROP ROLE*

# ecpg

## Name

ecpg — embedded SQL C preprocessor

## Synopsis

`ecpg [option...] file...`

## Description

`ecpg` is the embedded SQL preprocessor for C programs. It converts C programs with embedded SQL statements to normal C code by replacing the SQL invocations with special function calls. The output files can then be processed with any C compiler tool chain.

`ecpg` will convert each input file given on the command line to the corresponding C output file. Input files preferably have the extension `.pgc`, in which case the extension will be replaced by `.c` to determine the output file name. If the extension of the input file is not `.pgc`, then the output file name is computed by appending `.c` to the full file name. The output file name can also be overridden using the `-o` option.

This reference page does not describe the embedded SQL language. See Chapter 32 for more information on that topic.

## Options

`ecpg` accepts the following command-line arguments:

`-c`

Automatically generate certain C code from SQL code. Currently, this works for `EXEC SQL TYPE`.

`-C mode`

Set a compatibility mode. *mode* can be `INFORMIX` or `INFORMIX_SE`.

`-D symbol`

Define a C preprocessor symbol.

`-i`

Parse system include files as well.

`-I directory`

Specify an additional include path, used to find files included via `EXEC SQL INCLUDE`. Defaults are `.` (current directory), `/usr/local/include`, the PostgreSQL include directory which is defined at compile time (default: `/usr/local/pgsql/include`), and `/usr/include`, in that order.

`-o filename`

Specifies that `ecpg` should write all its output to the given *filename*.

`-r option`

Selects a run-time behavior. Currently, *option* can only be `no_indicator`.

`-t`

Turn on autocommit of transactions. In this mode, each SQL command is automatically committed unless it is inside an explicit transaction block. In the default mode, commands are committed only when `EXEC SQL COMMIT` is issued.

`-v`

Print additional information including the version and the include path.

`--help`

Show a brief summary of the command usage, then exit.

`--version`

Output version information, then exit.

## Notes

When compiling the preprocessed C code files, the compiler needs to be able to find the ECPG header files in the PostgreSQL include directory. Therefore, one might have to use the `-I` option when invoking the compiler (e.g., `-I/usr/local/pgsql/include`).

Programs using C code with embedded SQL have to be linked against the `libecpg` library, for example using the linker options `-L/usr/local/pgsql/lib -lecpg`.

The value of either of these directories that is appropriate for the installation can be found out using `pg_config`.

## Examples

If you have an embedded SQL C source file named `prog1.pgc`, you can create an executable program using the following sequence of commands:

```
ecpg prog1.pgc
cc -I/usr/local/pgsql/include -c prog1.c
cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg
```

# pg\_config

## Name

`pg_config` — retrieve information about the installed version of PostgreSQL

## Synopsis

`pg_config` [*option...*]

## Description

The `pg_config` utility prints configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries.

## Options

To use `pg_config`, supply one or more of the following options:

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files. (This will be an empty string if `--without-docdir` was specified when PostgreSQL was built.)

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

--localedir

Print the location of locale support files. (This will be an empty string if locale support was not configured when PostgreSQL was built.)

--mandir

Print the location of manual pages.

--sharedir

Print the location of architecture-independent support files.

--sysconfdir

Print the location of system-wide configuration files.

--pgxs

Print the location of extension makefiles.

--configure

Print the options that were given to the `configure` script when PostgreSQL was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

--cc

Print the value of the `CC` variable that was used for building PostgreSQL. This shows the C compiler used.

--cppflags

Print the value of the `CPPFLAGS` variable that was used for building PostgreSQL. This shows C compiler switches needed at preprocessing time (typically, `-I` switches).

--cflags

Print the value of the `CFLAGS` variable that was used for building PostgreSQL. This shows C compiler switches.

--cflags\_sl

Print the value of the `CFLAGS_SL` variable that was used for building PostgreSQL. This shows extra C compiler switches used for building shared libraries.

--ldflags

Print the value of the `LDFLAGS` variable that was used for building PostgreSQL. This shows linker switches.

--ldflags\_sl

Print the value of the `LDFLAGS_SL` variable that was used for building PostgreSQL. This shows linker switches used for building shared libraries.

--libs

Print the value of the `LIBS` variable that was used for building PostgreSQL. This normally contains `-l` switches for external libraries linked into PostgreSQL.

`--version`

Print the version of PostgreSQL.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

## Notes

The option `--includedir-server` was new in PostgreSQL 7.2. In prior releases, the server include files were installed in the same location as the client headers, which could be queried with the option `--includedir`. To make your package handle both cases, try the newer option first and test the exit status to see whether it succeeded.

The options `--docdir`, `--pkgincludedir`, `--localedir`, `--mandir`, `--sharedir`, `--sysconfdir`, `--cc`, `--cppflags`, `--cflags`, `--cflags_sl`, `--ldflags`, `--ldflags_sl`, and `--libs` are new in PostgreSQL 8.1.

In releases prior to PostgreSQL 7.1, before `pg_config` came to be, a method for finding the equivalent configuration information did not exist.

## Example

To reproduce the build configuration of the current PostgreSQL installation, run the following command:

```
eval `./configure 'pg_config --configure`
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

# pg\_dump

## Name

`pg_dump` — extract a PostgreSQL database into a script file or other archive file

## Synopsis

```
pg_dump [option...] [dbname]
```

## Description

`pg_dump` is a utility for backing up a PostgreSQL database. It makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to `psql`. Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications even on other SQL database products.

The alternative archive file formats must be used with `pg_restore` to rebuild the database. They allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file format is the “custom” format (`-Fc`). It allows for selection and reordering of all archived items, and is compressed by default. The tar format (`-Ft`) is not compressed and it is not possible to reorder data when loading, but it is otherwise quite flexible; moreover, it can be manipulated with standard Unix tools such as `tar`.

While running `pg_dump`, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

## Options

The following command-line options control the content and format of the output.

*dbname*

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

-a

--data-only

Dump only the data, not the schema (data definitions).

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

-b

--blobs

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified, so the `-b` switch is only useful to add large objects to selective dumps.

-c

--clean

Output commands to clean (drop) database objects prior to (the commands for) creating them.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

-C

--create

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database you connect to before running the script.)

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

-d

--inserts

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The `-D` option is safe against column order changes, though even slower.

-D

--column-inserts

--attribute-inserts

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

-E *encoding*

--encoding=*encoding*

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

```
-f file
--file=file
```

Send output to the specified file. If this is omitted, the standard output is used.

```
-F format
--format=format
```

Selects the format of the output. *format* can be one of the following:

```
p
plain
```

Output a plain-text SQL script file (the default).

```
c
custom
```

Output a custom archive suitable for input into `pg_restore`. This is the most flexible format in that it allows reordering of loading data as well as object definitions. This format is also compressed by default.

```
t
tar
```

Output a `tar` archive suitable for input into `pg_restore`. Using this archive format allows reordering and/or exclusion of database objects at the time the database is restored. It is also possible to limit which data is reloaded at restore time.

```
-i
--ignore-version
```

Ignore version mismatch between `pg_dump` and the database server.

`pg_dump` can dump from servers running previous releases of PostgreSQL, but very old versions are not supported anymore (currently, those prior to 7.0). Dumping from a server newer than `pg_dump` is likely not to work at all. Use this option if you need to override the version check (and if `pg_dump` then fails, don't say you weren't warned).

```
-n schema
--schema=schema
```

Dump only schemas matching *schema*; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. Also, the *schema* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see *Patterns*), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

**Note:** When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

**Note:** Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.

`-N schema`

`--exclude-schema=schema`

Do not dump any schemas matching the *schema* pattern. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns.

When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-O`

`--oids`

Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

`-O`

`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`-R`

`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`

`--schema-only`

Dump only the object definitions (schema), not data.

`-S username`

`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t table`

`--table=table`

Dump only tables (or views or sequences) matching *table*. Multiple tables can be selected by writing multiple `-t` switches. Also, the *table* parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands (see *Patterns*), so multiple tables can also be selected by writing

wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

**Note:** When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

**Note:** The behavior of the `-t` switch is not entirely upward compatible with pre-8.2 PostgreSQL versions. Formerly, writing `-t tab` would dump all tables named `tab`, but now it just dumps whichever one is visible in your default search path. To get the old behavior you can write `-t '*.tab'`. Also, you must write something like `-t sch.tab` to select a table in a particular schema, rather than the old locution of `-n sch -t tab`.

```
-T table
--exclude-table=table
```

Do not dump any tables matching the `table` pattern. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns.

When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

```
-v
--verbose
```

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

```
-x
--no-privileges
--no-acl
```

Prevent dumping of access privileges (grant/revoke commands).

```
--disable-dollar-quoting
```

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

```
--disable-triggers
```

This option is only relevant when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

```
--use-set-session-authorization
```

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using `SET SESSION AUTHORIZATION` will certainly require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

```
-Z 0..9
```

```
--compress=0..9
```

Specify the compression level to use in archive formats that support compression. (Currently only the custom archive format supports compression.)

The following command-line options control the database connection parameters.

```
-h host
```

```
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

```
-p port
```

```
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

```
-U username
```

```
--username=username
```

User name to connect as.

```
-W
```

```
--password
```

Force `pg_dump` to prompt for a password before connecting to a database.

This option is never essential, since `pg_dump` will automatically prompt for a password if the server demands password authentication. However, `pg_dump` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

pg\_dump internally executes `SELECT` statements. If you have problems running pg\_dump, make sure you are able to select information from the database using, for example, psql. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

If your database cluster has any local additions to the `template1` database, be careful to restore the output of pg\_dump into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

pg\_dump has a few limitations:

- When a data-only dump is chosen and the option `--disable-triggers` is used, pg\_dump emits commands to disable triggers on user tables before inserting the data and commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

Members of tar archives are limited to a size less than 8 GB. (This is an inherent limitation of the tar file format.) Therefore this format cannot be used if the textual representation of any one table exceeds that size. The total size of a tar archive and any of the other output formats is not limited, except possibly by the operating system.

The dump file produced by pg\_dump does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure good performance.

Because pg\_dump is used to transfer data to newer versions of PostgreSQL, the output of pg\_dump can be loaded into newer PostgreSQL databases. It also can read older PostgreSQL databases. However, it

usually cannot read newer PostgreSQL databases or produce dump output that can be loaded into older database versions. To do this, manual editing of the dump file might be required.

## Examples

To dump a database called `mydb` into a SQL-script file:

```
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
$ psql -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```
$ pg_dump -Fc mydb > db.dump
```

To reload an archive file into a (freshly created) database named `newdb`:

```
$ pg_restore -d newdb db.dump
```

To dump a single table named `mytab`:

```
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with `emp` in the `detroit` schema, except for the table named `employee_log`:

```
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```

To dump all schemas whose names start with `east` or `west` and end in `gsm`, excluding any schemas whose names contain the word `test`:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with `ts_`:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case (see *Patterns*). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t '"MixedCaseName"' mydb > mytab.sql
```

## See Also

`pg_dumpall`, `pg_restore`, `psql`

# pg\_dumpall

## Name

`pg_dumpall` — extract a PostgreSQL database cluster into a script file

## Synopsis

`pg_dumpall` [*option...*]

## Description

`pg_dumpall` is a utility for writing out (“dumping”) all PostgreSQL databases of a cluster into one script file. The script file contains SQL commands that can be used as input to `psql` to restore the databases. It does this by calling `pg_dump` for each database in a cluster. `pg_dumpall` also dumps global objects that are common to all databases. (`pg_dump` does not save these objects.) This currently includes information about database users and groups, and access permissions that apply to databases as a whole.

Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Shell operators should be used to redirect it into a file.

`pg_dumpall` needs to connect several times to the PostgreSQL server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 30.13 for more information.

## Options

The following command-line options control the content and format of the output.

`-a`

`--data-only`

Dump only the data, not the schema (data definitions).

`-c`

`--clean`

Include SQL commands to clean (drop) databases before recreating them. `DROP` commands for roles and tablespaces are added as well.

-d

--inserts

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Note that the restore might fail altogether if you have rearranged column order. The `-D` option is safer, though even slower.

-D

--column-inserts

--attribute-inserts

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases.

-f *filename*

--file=*filename*

Send output to the specified file. If this is omitted, the standard output is used.

-g

--globals-only

Dump only global objects (roles and tablespaces), no databases.

-i

--ignore-version

Ignore version mismatch between `pg_dumpall` and the database server.

`pg_dumpall` can handle databases from previous releases of PostgreSQL, but very old versions are not supported anymore (currently prior to 7.0). Use this option if you need to override the version check (and if `pg_dumpall` then fails, don't say you weren't warned).

-o

--oids

Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

-O

--no-owner

Do not output commands to set ownership of objects to match the original database. By default, `pg_dumpall` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`.

-r

--roles-only

Dump only roles, no databases or tablespaces.

`-s`  
`--schema-only`  
 Dump only the object definitions (schema), not data.

`-S username`  
`--superuser=username`  
 Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used. (Usually, it's better to leave this out, and instead start the resulting script as superuser.)

`-t`  
`--tablespaces-only`  
 Dump only tablespaces, no databases or roles.

`-v`  
`--verbose`  
 Specifies verbose mode. This will cause pg\_dumpall to output start/stop times to the dump file, and progress messages to standard error. It will also enable verbose output in pg\_dump.

`-x`  
`--no-privileges`  
`--no-acl`  
 Prevent dumping of access privileges (grant/revoke commands).

`--disable-dollar-quoting`  
 This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`  
 This option is only relevant when creating a data-only dump. It instructs pg\_dumpall to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably be careful to start the resulting script as a superuser.

`--use-set-session-authorization`  
 Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

The following command-line options control the database connection parameters.

**-h** *host*

**--host=***host*

Specifies the host name of the machine on which the database server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

**-l** *dbname*

**--database=***dbname*

Specifies the name of the database to connect to to dump global objects and discover what other databases should be dumped. If not specified, the “postgres” database will be used, and if that does not exist, “template1” will be used.

**-p** *port*

**--port=***port*

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

**-U** *username*

**--username=***username*

User name to connect as.

**-W**

**--password**

Force pg\_dumpall to prompt for a password before connecting to a database.

This option is never essential, since pg\_dumpall will automatically prompt for a password if the server demands password authentication. However, pg\_dumpall will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing **-W** to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it’s better to set up a `~/.pgpass` file than to rely on manual password entry.

## Environment

PGHOST

PGPORT

PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Notes

Since pg\_dumpall calls pg\_dump internally, some diagnostic messages will refer to pg\_dump.

Once restored, it is wise to run `ANALYZE` on each database so the optimizer has useful statistics. You can also run `vacuumdb -a -z` to analyze all databases.

`pg_dumpall` requires all needed tablespace directories to exist before the restore or database creation will fail for databases in non-default locations.

## Examples

To dump all databases:

```
$ pg_dumpall > db.out
```

To reload this database use, for example:

```
$ psql -f db.out postgres
```

(It is not important to which database you connect here since the script file created by `pg_dumpall` will contain the appropriate commands to create and connect to the saved databases.)

Check `pg_dump` for details on possible error conditions.

# pg\_restore

## Name

`pg_restore` — restore a PostgreSQL database from an archive file created by `pg_dump`

## Synopsis

```
pg_restore [option...] [filename]
```

## Description

`pg_restore` is a utility for restoring a PostgreSQL database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

`pg_restore` can operate in two modes. If a database name is specified, the archive is restored directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. The script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

Obviously, `pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the “dump data as `INSERT` commands” option, `pg_restore` will not be able to load the data using `COPY` statements.

## Options

`pg_restore` accepts the following command line arguments.

*filename*

Specifies the location of the archive file to be restored. If not specified, the standard input is used.

`-a`

`--data-only`

Restore only the data, not the schema (data definitions).

`-c`

`--clean`

Clean (drop) database objects before recreating them.

-C

--create

Create the database before restoring into it. (When this option is used, the database named with -d is used only to issue the initial CREATE DATABASE command. All data is restored into the database name that appears in the archive.)

-d *dbname*

--dbname=*dbname*

Connect to database *dbname* and restore directly into the database.

-e

--exit-on-error

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

-f *filename*

--file=*filename*

Specify output file for generated script, or for the listing when used with -l. Default is the standard output.

-F *format*

--format=*format*

Specify format of the archive. It is not necessary to specify the format, since pg\_restore will determine the format automatically. If specified, it can be one of the following:

t

tar

The archive is a tar archive. Using this archive format allows reordering and/or exclusion of schema elements at the time the database is restored. It is also possible to limit which data is reloaded at restore time.

c

custom

The archive is in the custom format of pg\_dump. This is the most flexible format in that it allows reordering of data load as well as schema elements. This format is also compressed by default.

-i

--ignore-version

Ignore database version checks.

-I *index*

--index=*index*

Restore definition of named index only.

-l

--list

List the contents of the archive. The output of this operation can be used with the -L option to restrict and reorder the items that are restored.

`-L list-file`

`--use-list=list-file`

Restore elements in `list-file` only, and in the order they appear in the file. Lines can be moved and can also be commented out by placing a `;` at the start of the line. (See below for examples.)

`-n namespace`

`--schema=schema`

Restore only objects that are in the named schema. This can be combined with the `-t` option to restore just a specific table.

`-O`

`--no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P function-name(argtype [, ...])`

`--function=function-name(argtype [, ...])`

Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents.

`-R`

`--no-reconnect`

This option is obsolete but still accepted for backwards compatibility.

`-s`

`--schema-only`

Restore only the schema (data definitions), not the data (table contents). Sequence current values will not be restored, either. (Do not confuse this with the `--schema` option, which uses the word "schema" in a different meaning.)

`-S username`

`--superuser=username`

Specify the superuser user name to use when disabling triggers. This is only relevant if `--disable-triggers` is used.

`-t table`

`--table=table`

Restore definition and/or data of named table only.

`-T trigger`

`--trigger=trigger`

Restore named trigger only.

`-v`

`--verbose`

Specifies verbose mode.

```
-x
--no-privileges
--no-acl
```

Prevent restoration of access privileges (grant/revoke commands).

```
--disable-triggers
```

This option is only relevant when performing a data-only restore. It instructs `pg_restore` to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-S`, or preferably run `pg_restore` as a PostgreSQL superuser.

```
--use-set-session-authorization
```

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, might not restore properly.

```
--no-data-for-failed-tables
```

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for PostgreSQL extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

`pg_restore` also accepts the following command line arguments for connection parameters:

```
-h host
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the `PGHOST` environment variable, if set, else a Unix domain socket connection is attempted.

```
-p port
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the `PGPORT` environment variable, if set, or a compiled-in default.

```
-U username
--username=username
```

User name to connect as.

`-W``--password`

Force `pg_restore` to prompt for a password before connecting to a database.

This option is never essential, since `pg_restore` will automatically prompt for a password if the server demands password authentication. However, `pg_restore` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`-1``--single-transaction`

Execute the restore as a single transaction (that is, wrap the emitted commands in `BEGIN/COMMIT`). This ensures that either all the commands complete successfully, or no changes are applied. This option implies `--exit-on-error`.

## Environment

`PGHOST``PGPORT``PGUSER`

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 30.12).

## Diagnostics

When a direct database connection is specified using the `-d` option, `pg_restore` internally executes SQL statements. If you have problems running `pg_restore`, make sure you are able to select information from the database using, for example, `psql`. Also, any default connection settings and environment variables used by the `libpq` front-end library will apply.

## Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of `pg_restore` are detailed below.

- When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to disable triggers on user tables before inserting the data then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.
- `pg_restore` will not restore large objects for a single table. If an archive contains large objects, then all large objects will be restored.

See also the `pg_dump` documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the optimizer has useful statistics.

## Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To reload the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don't use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
;
; Archive created at Fri Jul 28 22:28:36 2000
;   dbname: mydb
;   TOC Entries: 74
;   Compression: 0
;   Dump Version: 1.4-0
;   Format: CUSTOM
;
;
; Selected TOC Entries:
```

```

;
2; 145344 TABLE species postgres
3; 145344 ACL species
4; 145359 TABLE nt_header postgres
5; 145359 ACL nt_header
6; 145402 TABLE species_records postgres
7; 145402 ACL species_records
8; 145416 TABLE ss_old postgres
9; 145416 ACL ss_old
10; 145433 TABLE map_resolutions postgres
11; 145433 ACL map_resolutions
12; 145443 TABLE hs_old postgres
13; 145443 ACL hs_old

```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```

10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres

```

could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

## See Also

`pg_dump`, `pg_dumpall`, `psql`

# psql

## Name

psql — PostgreSQL interactive terminal

## Synopsis

```
psql [option...] [dbname [username]]
```

## Description

psql is a terminal-based front-end to PostgreSQL. It enables you to type in queries interactively, issue them to PostgreSQL, and see the query results. Alternatively, input can be from a file. In addition, it provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

## Options

```
-a  
--echo-all
```

Print all input lines to standard output as they are read. This is more useful for script processing rather than interactive mode. This is equivalent to setting the variable `ECHO` to `all`.

```
-A  
--no-align
```

Switches to unaligned output mode. (The default output mode is otherwise aligned.)

```
-c command  
--command command
```

Specifies that psql is to execute one command string, *command*, and then exit. This is useful in shell scripts.

*command* must be either a command string that is completely parsable by the server (i.e., it contains no psql specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands with this option. To achieve that, you could pipe the string into psql, like this: `echo '\x \\\ SELECT * FROM foo;' | psql`. (\\ is the separator meta-command.)

If the command string contains multiple SQL commands, they are processed in a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. This is different from the behavior when the same string is fed to psql's standard input.

`-d dbname`

`--dbname dbname`

Specifies the name of the database to connect to. This is equivalent to specifying *dbname* as the first non-option argument on the command line.

If this parameter contains an = sign, it is treated as a `conninfo` string. See Section 30.1 for more information.

`-e`

`--echo-queries`

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

`-E`

`--echo-hidden`

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study psql's internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` from within psql.

`-f filename`

`--file filename`

Use the file *filename* as the source of commands instead of reading commands interactively. After the file is processed, psql terminates. This is in many ways equivalent to the internal command `\i`.

If *filename* is `-` (hyphen), then standard input is read.

Using this option is subtly different from writing `psql < filename`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output that you would have gotten had you entered everything by hand.

`-F separator`

`--field-separator separator`

Use *separator* as the field separator for unaligned output. This is equivalent to `\pset fieldsep` or `\f`.

`-h hostname`

`--host hostname`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

`-H`

`--html`

Turn on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

`-l`

`--list`

List all available databases, then exit. Other non-connection options are ignored. This is similar to the internal command `\list`.

```
-L filename
--log-file filename
```

Write all query output into file *filename*, in addition to the normal output destination.

```
-o filename
--output filename
```

Put all query output into file *filename*. This is equivalent to the command `\o`.

```
-p port
--port port
```

Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the `PGPORT` environment variable or, if not set, to the port specified at compile time, usually 5432.

```
-P assignment
--pset assignment
```

Allows you to specify printing options in the style of `\pset` on the command line. Note that here you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write `-P format=latex`.

```
-q
--quiet
```

Specifies that psql should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. Within psql you can also set the `QUIET` variable to achieve the same effect.

```
-R separator
--record-separator separator
```

Use *separator* as the record separator for unaligned output. This is equivalent to the `\pset recordsep` command.

```
-s
--single-step
```

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

```
-S
--single-line
```

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

**Note:** This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

```
-t
--tuples-only
```

Turn off printing of column names and result row count footers, etc. This is equivalent to the `\t` command.

```
-T table_options
--table-attr table_options
```

Allows you to specify options to be placed within the HTML `table` tag. See `\pset` for details.

```
-U username
--username username
```

Connect to the database as the user *username* instead of the default. (You must have permission to do so, of course.)

```
-v assignment
--set assignment
--variable assignment
```

Perform a variable assignment, like the `\set` internal command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To just set a variable without a value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

```
-V
--version
```

Print the psql version and exit.

```
-W
--password
```

Force psql to prompt for a password before connecting to a database.

This option is never essential, since psql will automatically prompt for a password if the server demands password authentication. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

```
-x
--expanded
```

Turn on the expanded table formatting mode. This is equivalent to the `\x` command.

```
-X,
--no-psqlrc
```

Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

```
-1
--single-transaction
```

When psql executes a script with the `-f` option, adding this option wraps `BEGIN/COMMIT` around the script to execute it as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the script itself uses `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if the script contains any command that cannot be executed inside a transaction block, specifying this option will cause that command (and hence the whole transaction) to fail.

```
-?
--help
```

Show help about psql command line arguments, and exit.

## Exit Status

psql returns 0 to the shell if it finished normally, 1 if a fatal error of its own (out of memory, file not found) occurs, 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

## Usage

### Connecting To A Database

psql is a regular PostgreSQL client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server and what user name you want to connect as. psql can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all these options are required; there are useful defaults. If you omit the host name, psql will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to `localhost` on machines that don't have Unix-domain sockets. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default user name is your Unix user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults aren't quite right, you can save yourself some typing by setting the environment variables `PGDATABASE`, `PGHOST`, `PGPORT` and/or `PGUSER` to appropriate values. (For additional environment variables, see Section 30.12.) It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. See Section 30.13 for more information.

An alternative way to specify connection parameters is in a `conninfo` string, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
```

This way you can also use LDAP for connection parameter lookup as described in Section 30.15. See Section 30.1 for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

## Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string `=>`. For example:

```
$ psql testdb
Welcome to psql 8.3.1, the PostgreSQL interactive terminal.

Type:  \copyright for distribution terms
        \h for help with SQL commands
        \? for help with psql commands
        \g or terminate with semicolon to execute query
        \q to quit

testdb=>
```

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

Whenever a command is executed, psql also polls for asynchronous notification events generated by *LISTEN* and *NOTIFY*.

## Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands help make psql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, use two single quotes. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\digits` (octal), and `\xdigits` (hexadecimal).

If an unquoted argument begins with a colon (`:`), it is taken as a psql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (```) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" " name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\cd [ directory ]`

Changes the current working directory to *directory*. Without argument, changes to the current user's home directory.

**Tip:** To print your current working directory, use `!\pwd`.

`\C [ title ]`

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title title`. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

`\connect (or \c) [ dbname [ username ] [ host ] [ port ] ]`

Establishes a new connection to a PostgreSQL server. If the new connection is successfully made, the previous connection is closed. If any of *dbname*, *username*, *host* or *port* are omitted or specified as `-`, the value of that parameter from the previous connection is used. If there is no previous connection, the libpq default for the parameter's value is used.

If the connection attempt failed (wrong user name, access denied, etc.), the previous connection will only be kept if psql is in interactive mode. When executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand.

`\copy { table [ ( column_list ) ] | ( query ) } { from | to } { filename | stdin | stdout | pstdin | pstdout } [ with ] [ binary ] [ oids ] [ delimiter [ as ] 'character' ] [ null [ as ] 'string' ] [ csv [ header ] [ quote [ as ] 'character' ] [ escape [ as ] 'character' ] [ force quote column_list ] [ force not null column_list ] ]`

Performs a frontend (client) copy. This is an operation that runs an SQL *COPY* command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

The syntax of the command is similar to that of the SQL *COPY* command. Note that, because of this, special parsing rules apply to the `\copy` command. In particular, the variable substitution rules and backslash escapes do not apply.

`\copy ... from stdin | to stdout` reads/writes based on the command input and output respectively. All rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches EOF. Output is sent to the same place as command output. To read/write from psql's standard input or output, use `pstdin` or `pstdout`. This option is useful for populating tables in-line within a SQL script file.

**Tip:** This operation is not as efficient as the SQL `COPY` command because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

`\copyright`

Shows the copyright and distribution terms of PostgreSQL.

`\d [ pattern ]`

`\d+ [ pattern ]`

For each relation (table, view, index, or sequence) matching the *pattern*, show all columns, their types, the tablespace (if not the default) and any special attributes such as `NOT NULL` or defaults, if any. Associated indexes, constraints, rules, and triggers are also shown, as is the view definition if the relation is a view. ("Matching the pattern" is defined below.)

The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table.

**Note:** If `\d` is used without a *pattern* argument, it is equivalent to `\dtvs` which will show a list of all tables, views, and sequences. This is purely a convenience measure.

`\da [ pattern ]`

Lists all available aggregate functions, together with their return type and the data types they operate on. If *pattern* is specified, only aggregates whose names match the pattern are shown.

`\db [ pattern ]`

`\db+ [ pattern ]`

Lists all available tablespaces. If *pattern* is specified, only tablespaces whose names match the pattern are shown. If `+` is appended to the command name, each object is listed with its associated permissions.

`\dc [ pattern ]`

Lists all available conversions between character-set encodings. If *pattern* is specified, only conversions whose names match the pattern are listed.

`\dC`

Lists all available type casts.

`\dd [ pattern ]`

Shows the descriptions of objects matching the *pattern*, or of all visible objects if no argument is given. But in either case, only objects that have a description are listed. ("Object" covers aggregates,

functions, operators, types, relations (tables, views, indexes, sequences, large objects), rules, and triggers.) For example:

```
=> \dd version
```

Object descriptions			
Schema	Name	Object	Description
pg_catalog	version	function	PostgreSQL version string

(1 row)

Descriptions for objects can be created with the *COMMENT* SQL command.

```
\dD [ pattern ]
```

Lists all available domains. If *pattern* is specified, only matching domains are shown.

```
\df [ pattern ]
```

```
\df+ [ pattern ]
```

Lists available functions, together with their argument and return types. If *pattern* is specified, only functions whose names match the pattern are shown. If the form `\df+` is used, additional information about each function, including volatility, language, source code and description, is shown.

**Note:** To look up functions taking argument or returning values of a specific type, use your pager's search capability to scroll through the `\df` output.

To reduce clutter, `\df` does not show data type I/O functions. This is implemented by ignoring functions that accept or return type `cstring`.

```
\dF [ pattern ]
```

```
\dF+ [ pattern ]
```

Lists available text search configurations. If *pattern* is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

```
\dFd [ pattern ]
```

```
\dFd+ [ pattern ]
```

Lists available text search dictionaries. If *pattern* is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

```
\dFp [ pattern ]
```

```
\dFp+ [ pattern ]
```

Lists available text search parsers. If *pattern* is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

```
\dFt [ pattern ]
```

```
\dFt+ [ pattern ]
```

Lists available text search templates. If *pattern* is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

`\dg [ pattern ]`

Lists all database roles. If *pattern* is specified, only those roles whose names match the pattern are listed. (This command is now effectively the same as `\du`.)

`\distvS [ pattern ]`

This is not the actual command name: the letters *i*, *s*, *t*, *v*, *S* stand for index, sequence, table, view, and system table, respectively. You can specify any or all of these letters, in any order, to obtain a listing of all the matching objects. The letter *s* restricts the listing to system objects; without *s*, only non-system objects are shown. If *+* is appended to the command name, each object is listed with its associated description, if any.

If *pattern* is specified, only objects whose names match the pattern are listed.

`\dl`

This is an alias for `\lo_list`, which shows a list of large objects.

`\dn [ pattern ]`

`\dn+ [ pattern ]`

Lists all available schemas (namespaces). If *pattern* (a regular expression) is specified, only schemas whose names match the pattern are listed. Non-local temporary schemas are suppressed. If *+* is appended to the command name, each object is listed with its associated permissions and description, if any.

`\do [ pattern ]`

Lists available operators with their operand and return types. If *pattern* is specified, only operators whose names match the pattern are listed.

`\dp [ pattern ]`

Produces a list of all available tables, views and sequences with their associated access privileges. If *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.

The *GRANT* and *REVOKE* commands are used to set access privileges.

`\dT [ pattern ]`

`\dT+ [ pattern ]`

Lists all data types or only those that match *pattern*. The command form `\dT+` shows extra information.

`\du [ pattern ]`

Lists all database roles, or only those that match *pattern*.

`\edit (or \e) [ filename ]`

If *filename* is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of psql, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) This means also that if the query ends with (or rather contains) a semicolon, it is immediately executed. In other cases it will merely wait in the query buffer.

**Tip:** psql searches the environment variables `PSQL_EDITOR`, `EDITOR`, and `VISUAL` (in that order) for an editor to use. If all of them are unset, `vi` is used on Unix systems, `notepad.exe` on Windows systems.

`\echo text [ ... ]`

Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo `date`
```

```
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted `-n` the trailing newline is not written.

**Tip:** If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command.

`\encoding [ encoding ]`

Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\f [ string ]`

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). See also `\pset` for a generic way of setting output options.

`\g [ { filename | command } ]`

Sends the current query input buffer to the server and optionally stores the query's output in *filename* or pipes the output into a separate Unix shell executing *command*. A bare `\g` is virtually equivalent to a semicolon. A `\g` with argument is a “one-shot” alternative to the `\o` command.

`\help (or \h) [ command ]`

Gives syntax help on the specified SQL command. If *command* is not specified, then psql will list all the commands for which syntax help is available. If *command* is an asterisk (`*`), then syntax help on all SQL commands is shown.

**Note:** To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

`\H`

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

`\i filename`

Reads input from the file *filename* and executes it as though it had been typed on the keyboard.

**Note:** If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

```
\l (or \list)
\l+ (or \list+)
```

List the names, owners, and character set encodings of all the databases in the server. If `+` is appended to the command name, database descriptions are also displayed.

```
\lo_export oid filename
```

Reads the large object with OID `oid` from the database and writes it to `filename`. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system.

**Tip:** Use `\lo_list` to find out the large object's OID.

```
\lo_import filename [ comment ]
```

Stores the file into a PostgreSQL large object. Optionally, it associates the given comment with the object. Example:

```
foo=> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the `\lo_list` command.

Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

```
\lo_list
```

Shows a list of all PostgreSQL large objects currently stored in the database, along with any comments provided for them.

```
\lo_unlink oid
```

Deletes the large object with OID `oid` from the database.

**Tip:** Use `\lo_list` to find out the large object's OID.

```
\o [ {filename} | command ]
```

Saves future query results to the file `filename` or pipes future results into a separate Unix shell to execute `command`. If no arguments are specified, the query output will be reset to the standard output.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`), but not error messages.

**Tip:** To intersperse text output in between query results, use `\qecho`.

`\p`

Print the current query buffer to the standard output.

`\password [ username ]`

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE` command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

`\prompt [ text ] name`

Prompts the user to set variable *name*. An optional prompt, *text*, can be specified. (For multi-word prompts, use single-quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch is used, `\prompt` uses standard input and standard output.

`\pset parameter [ value ]`

This command sets options affecting the output of query result tables. *parameter* describes which option is to be set. The semantics of *value* depend thereon.

Adjustable printing options are:

*format*

Sets the output format to one of `unaligned`, `aligned`, `html`, `latex`, or `troff-ms`. Unique abbreviations are allowed. (That would mean one letter is enough.)

“Unaligned” writes all columns of a row on a line, separated by the currently active field separator. This is intended to create output that might be intended to be read in by other programs (tab-separated, comma-separated). “Aligned” mode is the standard, human-readable, nicely formatted text output that is default. The “HTML” and “LaTeX” modes put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! (This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper.)

*border*

The second argument must be a number. In general, the higher the number the more borders and lines the tables will have, but this depends on the particular format. In HTML mode, this will translate directly into the `border=...` attribute, in the others only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense.

*expanded (or x)*

You can specify an optional second argument, if it is provided it may be either `on` or `off` which will enable or disable expanded mode. If the second argument is not provided then we will toggle between regular and expanded format. When expanded format is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal “horizontal” mode.

Expanded mode is supported by all four output formats.

`null`

The second argument is a string that should be printed whenever a column is null. The default is not to print anything, which can easily be mistaken for, say, an empty string. Thus, one might choose to write `\pset null '(null)'`.

`fieldsep`

Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

`footer`

You can specify an optional second argument, if it is provided it may be either `on` or `off` which will enable or disable display of the default footer (`x rows`). If the second argument is not provided then we will toggle between on and off.

`numericlocale`

You can specify an optional second argument, if it is provided it may be either `on` or `off` which will enable or disable display of a locale-aware character to separate groups of digits to the left of the decimal marker. If the second argument is not provided then we will toggle between on and off.

`recordsep`

Specifies the record (line) separator to use in unaligned output mode. The default is a newline character.

`tuples_only (or t)`

You can specify an optional second argument, if it is provided it may be either `on` or `off` which will enable or disable the tuples only mode. If the second argument is not provided then we will toggle between tuples only and full display. Full display shows extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.

`title [ text ]`

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no argument is given, the title is unset.

`tableattr (or T) [ text ]`

Allows you to specify any attributes to be placed inside the HTML `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`.

`pager`

Controls use of a pager for query and psql help output. If the environment variable `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as `more`) is used.

When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate, i.e. the output is to a terminal and will not fit on the screen. (psql does not do a perfect job of estimating when to use the pager.) `\pset pager` turns the pager on and off. Pager can also be set to `always`, which causes the pager to be always used, or you can set the

pager to `on` which will enable the usage of the pager when appropriate, or you can set the pager to `off` which will disable the pager.

Illustrations on how these different formats look can be seen in the *Examples* section.

**Tip:** There are various shortcut commands for `\pset`. See `\a`, `\C`, `\H`, `\t`, `\T`, and `\x`.

**Note:** It is an error to call `\pset` without arguments. In the future this call might show the current status of all printing options.

`\q`

Quits the psql program.

`\qecho text [ ... ]`

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r`

Resets (clears) the query buffer.

`\s [ filename ]`

Print or save the command line history to *filename*. If *filename* is omitted, the history is written to the standard output. This option is only available if psql is configured to use the GNU Readline library.

`\set [ name [ value [ ... ] ] ]`

Sets the internal variable *name* to *value* or, if more than one value is given, to the concatenation of all of them. If no second argument is given, the variable is just set with no value. To unset a variable, use the `\unset` command.

Valid variable names can contain characters, digits, and underscores. See the section *Variables* below for details. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, psql treats several variables as special. They are documented in the section about variables.

**Note:** This command is totally separate from the SQL command *SET*.

`\t`

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.

`\T table_options`

Allows you to specify attributes to be placed within the `table` tag in HTML tabular output mode. This command is equivalent to `\pset tableattr table_options`.

`\timing`

Toggles a display of how long each SQL statement takes, in milliseconds.

`\w {filename | command}`

Outputs the current query buffer to the file *filename* or pipes it to the Unix command *command*.

`\x`

Toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

`\z [ pattern ]`

Produces a list of all available tables, views and sequences with their associated access privileges. If a *pattern* is specified, only tables, views and sequences whose names match the pattern are listed.

The *GRANT* and *REVOKE* commands are used to set access privileges.

This is an alias for `\dp` (“display privileges”).

`\! [ command ]`

Escapes to a separate Unix shell or executes the Unix command *command*. The arguments are not further interpreted, the shell will see them as is.

`\?`

Shows help information about the backslash commands.

## Patterns

The various `\d` commands accept a *pattern* parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO" "BAR"` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays all tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in Section 9.7.3, except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation

`.*`, `?` which is translated to `.`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `?` for `.`, `(R+|)` for `R*`, or `(R|)` for `R?`. `$` is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, `$` is automatically appended to your pattern). Write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

Whenever the *pattern* parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using the pattern `*`. To see all objects in the database, use the pattern `*.*`.

## Advanced features

### Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. To set variables, use the psql meta-command `\set`:

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon and use it as the argument of any slash command:

```
testdb=> \echo :foo
bar
```

**Note:** The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (or delete) a variable, use the command `\unset`.

psql's internal variable names can consist of letters, numbers, and underscores in any order and any number of them. A number of these variables are treated specially by psql. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

## AUTOCOMMIT

When `on` (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION SQL` command. When `off` or `unset`, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

**Note:** In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

**Note:** The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

## DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

## ECHO

If set to `all`, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or executed. To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `psql` merely prints all queries as they are sent to the server. The switch for this is `-e`.

## ECHO\_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and executed.

## ENCODING

The current client character set encoding.

## FETCH\_COUNT

If this variable is set to an integer value  $> 0$ , the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

**Tip:** Although you can use any output format with this feature, the default `aligned` format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

## HISTCONTROL

If this variable is set to `ignorespace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those above, all lines read in interactive mode are saved on the history list.

**Note:** This feature was shamelessly plagiarized from Bash.

## HISTFILE

The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
in ~/.psqlrc will cause psql to maintain a separate history for each database.
```

**Note:** This feature was shamelessly plagiarized from Bash.

## HISTSIZE

The number of commands to store in the command history. The default value is 500.

**Note:** This feature was shamelessly plagiarized from Bash.

## HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

## IGNOREEOF

If unset, sending an EOF character (usually **Control+D**) to an interactive session of psql will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**Note:** This feature was shamelessly plagiarized from Bash.

## LASTOID

The value of the last affected OID, as returned from an `INSERT` or `lo_insert` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

## ON\_ERROR\_ROLLBACK

When `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When `off` (the default), a statement in a transaction block that generates

an error aborts the entire transaction. The `on_error_rollback-on` mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and rolls back to the savepoint on error.

#### ON\_ERROR\_STOP

By default, if non-interactive scripts encounter an error, such as a malformed SQL command or internal meta-command, processing continues. This has been the traditional behavior of psql but it is sometimes not desirable. If this variable is set, script processing will immediately terminate. If the script was called from another script it will terminate in the same fashion. If the outermost script was not called from an interactive psql session but rather using the `-f` option, psql will return error code 3, to distinguish this case from fatal error conditions (error code 1).

#### PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

#### PROMPT1

#### PROMPT2

#### PROMPT3

These specify what the prompts psql issues should look like. See *Prompting* below.

#### QUIET

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

#### SINGLELINE

This variable is equivalent to the command line option `-s`.

#### SINGLESTEP

This variable is equivalent to the command line option `-s`.

#### USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

#### VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

### SQL Interpolation

An additional useful feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements. The syntax for this is again to prepend the variable name with a colon (`:`):

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would then query the table `my_table`. The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. You must make sure that it makes sense where you put it. Variable interpolation will not be performed into quoted SQL entities.

A popular application of this facility is to refer to the last inserted OID in subsequent statements to build a foreign key scenario. Another possible use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then proceed as above:

```
testdb=> \set content "" `cat my_file.txt` ""
testdb=> INSERT INTO my_table VALUES (:content);
```

One problem with this approach is that `my_file.txt` might contain single quotes. These need to be escaped so that they don't cause a syntax error when the second line is processed. This could be done with the program `sed`:

```
testdb=> \set content "" `sed -e "s/'/'/'g" < my_file.txt` ""
```

If you are using non-standard-conforming strings then you'll also need to double backslashes. This is a bit tricky:

```
testdb=> \set content "" `sed -e "s/'/'/'g" -e 's/\\/\\"/g' < my_file.txt` ""
```

Note the use of different shell quoting conventions so that neither the single quote marks nor the backslashes are special to the shell. Backslashes are still special to `sed`, however, so we need to double them. (Perhaps at one point you thought it was great that all Unix commands use the same escape character.)

Since colons can legally appear in SQL commands, the following rule applies: the character sequence “:name” is not changed unless “name” is the name of a variable that is currently set. In any case you can escape a colon with a backslash to protect it from substitution. (The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntax for array slices and type casts are PostgreSQL extensions, hence the conflict.)

### Prompting

The prompts psql issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run an SQL `COPY` command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M

The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:dir/name]`, if the Unix domain socket is not at the compiled in default location.

%m

The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a Unix domain socket.

`%>`

The port number at which the database server is listening.

`%n`

The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%/`

The name of the current database.

`%~`

Like `%/`, but the output is `~` (tilde) if the database is your default database.

`%#`

If the session user is a database superuser, then a `#`, otherwise a `>`. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%R`

In prompt 1 normally `=`, but `^` if in single-line mode, and `!` if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 the sequence is replaced by `-`, `*`, a single quote, a double quote, or a dollar sign, depending on whether psql expects more input because the command wasn't terminated yet, because you are inside a `/* ... */` comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

`%x`

Transaction status: an empty string when not in a transaction block, or `*` when in a transaction block, or `!` when in a failed transaction block, or `?` when the transaction state is indeterminate (for example, because there is no connection).

`%digits`

The character with the indicated octal code is substituted.

`%:name:`

The value of the psql variable *name*. See the section *Variables* for details.

`%`command``

The output of *command*, similar to ordinary “back-tick” substitution.

`%[ ... %]`

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `]`. Multiple pairs of these can occur within the prompt. For example:

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%[%033[0m%]%# '
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

**Note:** This feature was shamelessly plagiarized from tcsh.

### Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

## Environment

### PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. The use of the pager can be disabled by using the `\pset` command.

### PGDATABASE

Default connection database

### PGHOST

### PGPORT

### PGUSER

Default connection parameters

### PSQL\_EDITOR

### EDITOR

### VISUAL

Editor used by the `\e` command. The variables are examined in the order listed; the first that is set is used.

### SHELL

Command executed by the `\!` command.

### TMPDIR

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Files

- Before starting up, psql attempts to read and execute commands from the system-wide `psqlrc` file and the user's `~/.psqlrc` file. (On Windows, the user's startup file is named `%APPDATA%\postgresql\psqlrc.conf`.) See `PREFIX/share/psqlrc.sample` for information on setting up the system-wide file. It could be used to set up the client or the server to taste (using the `\set` and `SET` commands).
- Both the system-wide `psqlrc` file and the user's `~/.psqlrc` file can be made version-specific by appending a dash and the PostgreSQL release number, for example `~/.psqlrc-8.3.1`. A matching version-specific file will be read in preference to a non-version-specific file.
- The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

## Notes

- In an earlier life psql allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. For compatibility this is still supported to some extent, but we are not going to explain the details here as this use is discouraged. If you get strange messages, keep this in mind. For example:

```
testdb=> \foo
Field separator is "oo".
which is perhaps not what one would expect.
```

- psql only works smoothly with servers of the same version. That does not mean other combinations will fail outright, but subtle and not-so-subtle problems might come up. Backslash commands are particularly likely to fail if the server is of a different version.

## Notes for Windows users

psql is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

## Examples

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (
testdb(> first integer not null default 0,
testdb(> second text)
testdb-> ;
CREATE TABLE
```

Now look at the table definition again:

```
testdb=> \d my_table
           Table "my_table"
Attribute | Type   | Modifier
-----+-----+-----
first     | integer | not null default 0
second    | text    |
```

Now we change the prompt to something more interesting:

```
testdb=> \set PROMPT1 '%n%m %~%R%# '
peter@localhost testdb=>
```

Let's assume you have filled the table with data and want to take a look at it:

```
peter@localhost testdb=> SELECT * FROM my_table;
 first | second
-----+-----
      1 | one
      2 | two
      3 | three
      4 | four
(4 rows)
```

You can display tables in different ways by using the `\pset` command:

```
peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
+-----+-----+
| first | second |
+-----+-----+
|      1 | one    |
|      2 | two    |
|      3 | three  |
|      4 | four   |
+-----+-----+
(4 rows)
```

```
peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
first second
```

```

-----
 1 one
 2 two
 3 three
 4 four
(4 rows)

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ","
Field separator is ",".
peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4

```

Alternatively, use the short commands:

```

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
-[ RECORD 1 ]-
first  | 1
second | one
-[ RECORD 2 ]-
first  | 2
second | two
-[ RECORD 3 ]-
first  | 3
second | three
-[ RECORD 4 ]-
first  | 4
second | four

```

# reindexdb

## Name

reindexdb — reindex a PostgreSQL database

## Synopsis

```
reindexdb [connection-option...] [--table | -t table] [--index | -i index] [dbname]  
reindexdb [connection-option...] [--all | -a]  
reindexdb [connection-option...] [--system | -s] [dbname]
```

## Description

reindexdb is a utility for rebuilding indexes in a PostgreSQL database.

reindexdb is a wrapper around the SQL command *REINDEX*. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

## Options

reindexdb accepts the following command-line arguments:

-a

--all

Reindex all databases.

[-d] *dbname*

[--dbname] *dbname*

Specifies the name of the database to be reindexed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e

--echo

Echo the commands that reindexdb generates and sends to the server.

-i *index*

--index *index*

Recreate *index* only.

-q

--quiet

Do not display progress messages.

```
-s
--system
```

Reindex database's system catalogs.

```
-t table
--table table
```

Reindex *table* only.

reindexdb also accepts the following command-line arguments for connection parameters:

```
-h host
--host host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username username
```

User name to connect as.

```
-W
--password
```

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *REINDEX* and *psql* for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

reindexdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 30.13 for more information.

## Examples

To reindex the database `test`:

```
$ reindexdb test
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table foo --index bar abcd
```

## See Also

*REINDEX*

# vacuumdb

## Name

vacuumdb — garbage-collect and analyze a PostgreSQL database

## Synopsis

```
vacuumdb [connection-option...] [--full | -f] [--verbose | -v] [--analyze | -z] [--table | -t table [(  
column [...])]] [dbname]  
vacuumdb [connection-options...] [--all | -a] [--full | -f] [--verbose | -v] [--analyze | -z]
```

## Description

vacuumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

vacuumdb is a wrapper around the SQL command *VACUUM*. There is no effective difference between vacuuming databases via this utility and via other methods for accessing the server.

## Options

vacuumdb accepts the following command-line arguments:

-a  
--all

Vacuum all databases.

[-d] *dbname*  
[--dbname] *dbname*

Specifies the name of the database to be cleaned or analyzed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e  
--echo

Echo the commands that vacuumdb generates and sends to the server.

-f  
--full

Perform “full” vacuuming.

`-q`  
`--quiet`

Do not display progress messages.

`-t table [ (column [,...]) ]`  
`--table table [ (column [,...]) ]`

Clean or analyze *table* only. Column names can be specified only in conjunction with the `--analyze` option.

**Tip:** If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

`-v`  
`--verbose`

Print detailed information during processing.

`-z`  
`--analyze`

Calculate statistics for use by the optimizer.

`vacuumdb` also accepts the following command-line arguments for connection parameters:

`-h host`  
`--host host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username username`

User name to connect as.

`-W`  
`--password`

Force `vacuumdb` to prompt for a password before connecting to a database.

This option is never essential, since `vacuumdb` will automatically prompt for a password if the server demands password authentication. However, `vacuumdb` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Environment

PGDATABASE  
PGHOST  
PGPORT  
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 30.12).

## Diagnostics

In case of difficulty, see *VACUUM* and `psql` for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

## Notes

`vacuumdb` might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases. See Section 30.13 for more information.

## Examples

To clean the database `test`:

```
$ vacuumdb test
```

To clean and analyze for the optimizer a database named `bigdb`:

```
$ vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `xyzyz`, and analyze a single column `bar` of the table for the optimizer:

```
$ vacuumdb --analyze --verbose --table 'foo(bar)' xyzyz
```

# III. PostgreSQL Server Applications

This part contains reference information for PostgreSQL server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in Reference II, *PostgreSQL Client Applications*.

# initdb

## Name

`initdb` — create a new PostgreSQL database cluster

## Synopsis

```
initdb [option...] --pgdata |-D directory
```

## Description

`initdb` creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the `template1` and `postgres` databases. When you later create a new database, everything in the `template1` database is copied. (Therefore, anything installed in `template1` is automatically copied into each database created later.) The `postgres` database is a default database meant for use by users, utilities and third party applications.

Although `initdb` will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use `chown` to assign ownership of that directory to the database user account, then `su` to become the database user to run `initdb`.

`initdb` must be run as the user that will own the server process, because the server needs to have access to the files and directories that `initdb` creates. Since the server cannot be run as root, you must not run `initdb` as root either. (It will in fact refuse to do so.)

`initdb` initializes the database cluster's default locale and character set encoding. The collation order (`LC_COLLATE`) and character set classes (`LC_CTYPE`, e.g. `upper`, `lower`, `digit`) are fixed for all databases and cannot be changed. Collation orders other than `C` or `POSIX` also have a performance penalty. For these reasons it is important to choose the right locale when running `initdb`. The remaining locale categories can be changed later when the server is started. All server locale values (`lc_*`) can be displayed via `SHOW ALL`. More details can be found in Section 22.1.

The character set encoding can be set separately for a database when it is created. `initdb` determines the encoding for the `template1` database, which will serve as the default for all other databases. To alter the default encoding use the `--encoding` option. More details can be found in Section 22.2.

## Options

```
-A authmethod
--auth=authmethod
```

This option specifies the authentication method for local users used in `pg_hba.conf`. Do not use `trust` unless you trust all local users on your system. `Trust` is the default for ease of installation.

```
-D directory
--pgdata=directory
```

This option specifies the directory where the database cluster should be stored. This is the only information required by `initdb`, but you can avoid writing it by setting the `PGDATA` environment variable, which can be convenient since the database server (`postgres`) can find the database directory later by the same variable.

```
-E encoding
--encoding=encoding
```

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or `SQL_ASCII` if that does not work. The character sets supported by the PostgreSQL server are described in Section 22.2.1.

```
--locale=locale
```

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that `initdb` runs in. Locale support is described in Section 22.1.

```
--lc-collate=locale
--lc-ctype=locale
--lc-messages=locale
--lc-monetary=locale
--lc-numeric=locale
--lc-time=locale
```

Like `--locale`, but only sets the locale in the specified category.

```
-X directory
--xlogdir=directory
```

This option specifies the directory where the transaction log should be stored.

```
-U username
--username=username
```

Selects the user name of the database superuser. This defaults to the name of the effective user running `initdb`. It is really not important what the superuser's name is, but one might choose to keep the customary name `postgres`, even if the operating system user's name is different.

```
-W
--pwprompt
```

Makes `initdb` prompt for a password to give the database superuser. If you don't plan on using password authentication, this is not important. Otherwise you won't be able to use password authentication until you have a password set up.

`--pwfile=filename`

Makes `initdb` read the database superuser's password from a file. The first line of the file is taken as the password.

Other, less commonly used, parameters are also available:

`-d`

`--debug`

Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program `initdb` uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

`-L directory`

Specifies where `initdb` should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

`-n`

`--noclean`

By default, when `initdb` determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

## Environment

`PGDATA`

Specifies the directory where the database cluster is to be stored; can be overridden using the `-D` option.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 30.12).

## See Also

`postgres`

# ipcclean

## Name

`ipcclean` — remove shared memory and semaphores from a failed PostgreSQL server

## Synopsis

```
ipcclean
```

## Description

`ipcclean` removes all shared memory segments and semaphore sets owned by the current user. It is intended to be used for cleaning up after a crashed PostgreSQL server (`postgres`). Note that immediately restarting the server will also clean up shared memory and semaphores, so this command is of little real utility.

Only the database administrator should execute this program as it can cause bizarre behavior (i.e., crashes) if run during multiuser execution. If this command is executed while a server is running, the shared memory and semaphores allocated by that server will be deleted, which would have rather severe consequences for that server.

## Notes

This script is a hack, but in the many years since it was written, no one has come up with an equally effective and portable solution. Since `postgres` can now clean up by itself, it is unlikely that `ipcclean` will be improved upon in the future.

The script makes assumptions about the output format of the `ipcs` utility which might not be true across different operating systems. Therefore, it might not work on your particular OS. It's wise to look at the script before trying it.

# pg\_controldata

## Name

`pg_controldata` — display control information of a PostgreSQL database cluster

## Synopsis

```
pg_controldata [datadir]
```

## Description

`pg_controldata` prints information initialized during `initdb`, such as the catalog version and server locale. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable `PGDATA`.

## Environment

`PGDATA`

Default data directory location

# pg\_ctl

## Name

`pg_ctl` — start, stop, or restart a PostgreSQL server

## Synopsis

```
pg_ctl start [-w] [-t seconds] [-s] [-D datadir] [-l filename] [-o options] [-p path] [-c]
pg_ctl stop [-W] [-t seconds] [-s] [-D datadir] [-m s[mart] | f[ast] | i[mmediate] ]
pg_ctl restart [-w] [-t seconds] [-s] [-D datadir] [-c] [-m s[mart] | f[ast] | i[mmediate] ] [-o options]
pg_ctl reload [-s] [-D datadir]
pg_ctl status [-D datadir]
pg_ctl kill [signal_name] [process_id]
pg_ctl register [-N servicename] [-U username] [-P password] [-D datadir] [-w] [-t seconds] [-o options]
pg_ctl unregister [-N servicename]
```

## Description

`pg_ctl` is a utility for starting, stopping, or restarting the PostgreSQL backend server (`postgres`), or displaying the status of a running server. Although the server can be started manually, `pg_ctl` encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

In `start` mode, a new server is launched. The server is started in the background, and standard input is attached to `/dev/null`. The standard output and standard error are either appended to a log file (if the `-l` option is used), or redirected to `pg_ctl`'s standard output (not standard error). If no log file is chosen, the standard output of `pg_ctl` should be redirected to a file or piped to another process such as a log rotating program like `rotatelog`s; otherwise `postgres` will write its output to the controlling terminal (from the background) and will not leave the shell's process group.

In `stop` mode, the server that is running in the specified data directory is shut down. Three different shutdown methods can be selected with the `-m` option: “Smart” mode waits for all the clients to disconnect. This is the default. “Fast” mode does not wait for clients to disconnect. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes without a clean shutdown. This will lead to a recovery run on restart.

`restart` mode effectively executes a stop followed by a start. This allows changing the `postgres` command-line options.

`reload` mode simply sends the `postgres` process a `SIGHUP` signal, causing it to reread its configuration files (`postgresql.conf`, `pg_hba.conf`, etc.). This allows changing of configuration-file options that do not require a complete restart to take effect.

`status` mode checks whether a server is running in the specified data directory. If it is, the PID and the command line options that were used to invoke it are displayed.

`kill` mode allows you to send a signal to a specified process. This is particularly valuable for Microsoft Windows which does not have a kill command. Use `--help` to see a list of supported signal names.

`register` mode allows you to register a system service on Microsoft Windows.

`unregister` mode allows you to unregister a system service on Microsoft Windows, previously registered with the `register` command.

## Options

`-c`

Attempt to allow server crashes to produce core files, on platforms where this available, by lifting any soft resource limit placed on them. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.

`-D datadir`

Specifies the file system location of the database files. If this is omitted, the environment variable `PGDATA` is used.

`-l filename`

Append the server log output to *filename*. If the file does not exist, it is created. The umask is set to 077, so access to the log file from other users is disallowed by default.

`-m mode`

Specifies the shutdown mode. *mode* can be `smart`, `fast`, or `immediate`, or the first letter of one of these three.

`-o options`

Specifies options to be passed directly to the `postgres` command.

The options are usually surrounded by single or double quotes to ensure that they are passed through as a group.

`-p path`

Specifies the location of the `postgres` executable. By default the `postgres` executable is taken from the same directory as `pg_ctl`, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the `postgres` executable was not found.

`-s`

Only print errors, no informational messages.

`-t`

The number of seconds to wait when waiting for start or shutdown to complete.

**-w**

Wait for the start or shutdown to complete. The default wait time is 60 seconds. This is the default option for shutdowns. A successful shutdown is indicated by removal of the PID file. For starting up, a successful `psql -l` indicates success. `pg_ctl` will attempt to use the proper port for `psql`. If the environment variable `PGPORT` exists, that is used. Otherwise, it will see if a port has been set in the `postgresql.conf` file. If neither of those is used, it will use the default port that PostgreSQL was compiled with (5432 by default). When waiting, `pg_ctl` will return an accurate exit code based on the success of the startup or shutdown.

**-W**

Do not wait for start or shutdown to complete. This is the default for starts and restarts.

## Options for Windows

**-N** *servicename*

Name of the system service to register. The name will be used as both the service name and the display name.

**-P** *password*

Password for the user to start the service.

**-U** *username*

User name for the user to start the service. For domain users, use the format `DOMAIN\username`.

## Environment

`PGDATA`

Default data directory location.

`PGPORT`

Default port for `psql` (used by the `-w` option).

For additional server variables, see `postgres`. This utility, like most other PostgreSQL utilities, also uses the environment variables supported by `libpq` (see Section 30.12).

## Files

`postmaster.pid`

The existence of this file in the data directory is used to help `pg_ctl` determine if the server is currently running or not.

`postmaster.opts.default`

If this file exists in the data directory, `pg_ctl` (in `start` mode) will pass the contents of the file as options to the `postgres` command, unless overridden by the `-o` option.

postmaster.opts

If this file exists in the data directory, pg\_ctl (in `restart` mode) will pass the contents of the file as options to postgres, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

postgresql.conf

This file, located in the data directory, is parsed to find the proper port to use with psql when the `-w` is given in `start` mode.

## Notes

Waiting for complete start is not a well-defined operation and might fail if access control is set up so that a local client cannot connect without manual interaction (e.g., password authentication). For additional connection variables, see Section 30.12, and for passwords, also see Section 30.13.

## Examples

### Starting the Server

To start up a server:

```
$ pg_ctl start
```

An example of starting the server, blocking until the server has come up is:

```
$ pg_ctl -w start
```

For a server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

### Stopping the Server

```
$ pg_ctl stop
```

stops the server. Using the `-m` switch allows one to control *how* the backend shuts down.

## Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again except that `pg_ctl` saves and reuses the command line options that were passed to the previously running instance. To restart the server in the simplest form, use:

```
$ pg_ctl restart
```

To restart server, waiting for it to shut down and to come up:

```
$ pg_ctl -w restart
```

To restart using port 5433 and disabling `fsync` after restarting:

```
$ pg_ctl -o "-F -p 5433" restart
```

## Showing the Server Status

Here is a sample status output from `pg_ctl`:

```
$ pg_ctl status
pg_ctl: server is running (pid: 13718)
Command line was:
/usr/local/pgsql/bin/postgres '-D' '/usr/local/pgsql/data' '-p' '5433' '-B' '128'
```

This is the command line that would be invoked in restart mode.

# pg\_resetxlog

## Name

`pg_resetxlog` — reset the write-ahead log and other control information of a PostgreSQL database cluster

## Synopsis

```
pg_resetxlog [-f] [-n] [-ooid ] [-x xid ] [-e xid_epoch ] [-m mxid ] [-O mxoff ] [-l  
timelineid,fileid,seg ] datadir
```

## Description

`pg_resetxlog` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetxlog` does not use the environment variable `PGDATA`.

If `pg_resetxlog` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) switch. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, WAL starting address, and database locale fields. The first six of these can be set using the switches discussed below. `pg_resetxlog`'s own environment is the source for its guess at the locale fields; take care that `LANG` and so forth match the environment that `initdb` was run in. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

The `-o`, `-x`, `-e`, `-m`, `-O`, and `-l` switches allow the next OID, next transaction ID, next transaction ID's epoch, next multitransaction ID, next multitransaction offset, and WAL starting address values to be set manually. These are only needed when `pg_resetxlog` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as follows:

- A safe value for the next transaction ID (`-x`) can be determined by looking for the numerically largest file name in the directory `pg_clog` under the data directory, adding one, and then multiplying by 1048576. Note that the file names are in hexadecimal. It is usually easiest to specify the switch value in hexadecimal too. For example, if 0011 is the largest entry in `pg_clog`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).

- A safe value for the next multitransaction ID (`-m`) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536. As above, the file names are in hexadecimal, so the easiest way to do this is to specify the switch value in hexadecimal and add four zeroes.
- A safe value for the next multitransaction offset (`-o`) can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 65536. As above, the file names are in hexadecimal, so the easiest way to do this is to specify the switch value in hexadecimal and add four zeroes.
- The WAL starting address (`-l`) should be larger than any WAL segment file name currently existing in the directory `pg_xlog` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. Do not choose a value larger than 255 (0xFF) for the third part; instead increment the second part and reset the third part to 0. For example, if 00000001000000320000004A is the largest entry in `pg_xlog`, `-l 0x1,0x32,0x4B` will work; but if the largest entry is 000000010000003A000000FF, choose `-l 0x1,0x3B,0x0` or more.

**Note:** `pg_resetxlog` itself looks at the files in `pg_xlog` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_xlog`, such as entries in an offline archive; or if the contents of `pg_xlog` have been lost entirely.

- There is no comparably easy way to determine a next OID that’s beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.
- The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetxlog`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

The `-n` (no operation) switch instructs `pg_resetxlog` to print the values reconstructed from `pg_control` and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetxlog` to proceed for real.

## Notes

This command must not be used when the server is running. `pg_resetxlog` will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow `pg_resetxlog` to run. But before you do so, make doubly certain that there is no server process still alive.

# postgres

## Name

`postgres` — PostgreSQL database server

## Synopsis

```
postgres [option...]
```

## Description

`postgres` is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running `postgres` instance. The `postgres` instance then starts a separate server process to handle the connection.

One `postgres` instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one `postgres` instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When `postgres` starts it needs to know the location of the data area. The location must be specified by the `-D` option or the `PGDATA` environment variable; there is no default. Typically, `-D` or `PGDATA` points directly to the data area directory created by `initdb`. Other possible file layouts are discussed in Section 18.2.

By default `postgres` starts in the foreground and prints log messages to the standard error stream. In practical applications `postgres` should be started as a background process, perhaps at boot time.

The `postgres` command can also be called in single-user mode. The primary use for this mode is during bootstrapping by `initdb`. Sometimes it is used for debugging or disaster recovery (but note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen). When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

## Options

`postgres` accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 18. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable `PGOPTIONS` is set, then libpq-based clients will pass that string to the server, which will interpret it as `postgres` command-line options.

## General Purpose

`-A 0|1`

Enables run-time assertion checks, which is a debugging aid to detect programming mistakes. This option is only available if assertions were enabled when PostgreSQL was compiled. If so, the default is on.

`-B nbuffers`

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the `shared_buffers` configuration parameter.

`-C name=value`

Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 18. Most of the other command line options are in fact short forms of such a parameter assignment. `-c` can appear multiple times to set multiple parameters.

`-d debug-level`

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass `-d 0` for a specific session, which will prevent the server log level of the parent `postgres` process from being propagated to this session.

`-D datadir`

Specifies the file system location of the data directory or configuration file(s). See Section 18.2 for details.

`-e`

Sets the default date style to “European”, that is `DMY` ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

`-F`

Disables `fsync` calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the `fsync` configuration parameter. Read the detailed documentation before using this!

`-h hostname`

Specifies the IP host name or address on which `postgres` is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or `*` to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the `listen_addresses` configuration parameter.

`-i`

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting `listen_addresses` to `*` in `postgresql.conf` or via `-h`.

This option is deprecated since it does not allow access to the full functionality of `listen_addresses`. It's usually better to set `listen_addresses` directly.

`-k directory`

Specifies the directory of the Unix-domain socket on which `postgres` is to listen for connections from client applications. The default is normally `/tmp`, but can be changed at build time.

`-l`

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 17.8.

`-N max-connections`

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by `initdb`. Specifying this option is equivalent to setting the `max_connections` configuration parameter.

`-o extra-options`

The command-line-style options specified in `extra-options` are passed to all server processes started by this `postgres` process. If the option string contains any spaces, the entire string must be quoted.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the `postgres` command line.

`-p port`

Specifies the TCP/IP port or local Unix domain socket file extension on which `postgres` is to listen for connections from client applications. Defaults to the value of the `PGPORT` environment variable, or if `PGPORT` is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or `PGPORT`.

`-s`

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

`-S work-mem`

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the `work_mem` configuration parameter in Section 18.4.1.

`--name=value`

Sets a named run-time parameter; a shorter form of `-c`.

`--describe-config`

This option dumps out the server's internal configuration variables, descriptions, and defaults in tab-delimited `COPY` format. It is designed primarily for use by administration tools.

## Semi-internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

`-f { s | i | m | n | h }`

Forbids the use of particular scan and join methods: `s` and `i` disable sequential and index scans respectively, while `n`, `m`, and `h` disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the `-fs` and `-fn` options simply discourage the optimizer from using those plan types if it has any other alternative.

`-n`

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.

`-O`

Allows the structure of system tables to be modified. This is used by `initdb`.

`-P`

Ignore system indexes when reading system tables (but still update the indexes when modifying the tables). This is useful when recovering from damaged system indexes.

`-t pa[rser] | pl[anner] | e[xecutor]`

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the `-s` option.

`-T`

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that `postgres` will stop all other server processes by sending the signal `SIGSTOP`, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.

`-v protocol`

Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

`-W seconds`

A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

## Options for single-user mode

The following options only apply to the single-user mode.

`--single`

Selects the single-user mode. This must be the first argument on the command line.

*database*

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

`-E`

Echo all commands.

`-j`

Disables use of newline as a statement delimiter.

`-r filename`

Send all server log output to *filename*. In normal multiuser mode, this option is ignored, and stderr is used by all processes.

## Environment

PGCLIENTENCODING

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA

Default data directory location

PGDATESTYLE

Default value of the DateStyle run-time parameter. (The use of this environment variable is deprecated.)

PGPORT

Default port (preferably set in the configuration file)

TZ

Server time zone

## Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 17.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of PostgreSQL, and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

## Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, *do not* use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command.

The `postgres` server uses `SIGTERM` to tell subordinate server processes to quit normally and `SIGQUIT` to terminate without the normal cleanup. These signals *should not* be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

## Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

## Usage

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one.

But if you use the `-j` command line switch, then newline does not terminate command entry. In this case, the server will read the standard input until the end-of-file (EOF) marker, then process the input as a single command string. Backslash-newline is not treated specially in this case.

To quit the session, type EOF (**Control+D**, usually). If you've used `-j`, two consecutive EOFs are needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example).

## Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 </dev/null &
```

To start `postgres` with a specific port:

```
$ postgres -p 1234
```

This command will start up `postgres` communicating through the port 1234. In order to connect to this server using `psql`, you would need to run it as

```
$ psql -p 1234
```

or set the environment variable `PGPORT`:

```
$ export PGPORT=1234
$ psql
```

Named run-time parameters can be set in either of these styles:

```
$ postgres -c work_mem=1234
$ postgres --work-mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

# VII. Internals

This part contains assorted information that might be of use to PostgreSQL developers.

# Chapter 43. Overview of PostgreSQL Internals

**Author:** This chapter originated as part of *Enhancement of the ANSI SQL Implementation of PostgreSQL*, Stefan Simkovics' Master's Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of PostgreSQL, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

## 43.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.
2. The *parser stage* checks the query transmitted by the application program for correct syntax and creates a *query tree*.
3. The *rewrite system* takes the query tree created by the parser stage and looks for any *rules* (stored in the *system catalogs*) to apply to the query tree. It performs the transformations given in the *rule bodies*.

One application of the rewrite system is in the realization of *views*. Whenever a query against a view (i.e. a *virtual table*) is made, the rewrite system rewrites the user's query to a query that accesses the *base tables* given in the *view definition* instead.

4. The *planner/optimizer* takes the (rewritten) query tree and creates a *query plan* that will be the input to the *executor*.

It does so by first creating all possible *paths* leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the *plan tree* and retrieves rows in the way represented by the plan. The executor makes use of the *storage system* while scanning relations, performs *sorts* and *joins*, evaluates *qualifications* and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL's internal control and data structures.

## 43.2. How Connections are Established

PostgreSQL is implemented using a simple “process per user” client/server model. In this model there is one *client process* connected to exactly one *server process*. As we do not know ahead of time how many connections will be made, we have to use a *master process* that spawns a new server process every time a connection is requested. This master process is called `postgres` and listens at a specified TCP/IP port for incoming connections. Whenever a request for a connection is detected the `postgres` process spawns a new server process. The server tasks communicate with each other using *semaphores* and *shared memory* to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 45. Many clients are based on the C-language library `libpq`, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the *backend* (server). The query is transmitted using plain text, i.e. there is no parsing done in the *frontend* (client). The server parses the query, creates an *execution plan*, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

## 43.3. The Parser Stage

The *parser stage* consists of two parts:

- The *parser* defined in `gram.y` and `scan.l` is built using the Unix tools `yacc` and `lex`.
- The *transformation process* does modifications and augmentations to the data structures returned by the parser.

### 43.3.1. Parser

The parser has to check the query string (which arrives as plain ASCII text) for valid syntax. If the syntax is correct a *parse tree* is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools `yacc` and `lex`.

The *lexer* is defined in the file `scan.l` and is responsible for recognizing *identifiers*, the *SQL key words* etc. For every key word or identifier that is found, a *token* is generated and handed to the parser.

The parser is defined in the file `gram.y` and consists of a set of *grammar rules* and *actions* that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file `scan.l` is transformed to the C source file `scan.c` using the program `lex` and `gram.y` is transformed to `gram.c` using `yacc`. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time `lex` or `yacc` is called.

**Note:** The mentioned transformations and compilations are normally done automatically using the *makefiles* shipped with the PostgreSQL source distribution.

A detailed description of yacc or the grammar rules given in `gram.y` would be beyond the scope of this paper. There are many books and documents dealing with lex and yacc. You should be familiar with yacc before you start to study the grammar given in `gram.y` otherwise you won't understand what happens there.

### 43.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the *transformation process* takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the *query tree*.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (`BEGIN`, `ROLLBACK`, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as `SELECT` or `UPDATE`), it is okay to start a transaction if we're not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a `FuncCall` node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a `FuncExpr` or `Aggref` node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

## 43.4. The PostgreSQL Rule System

PostgreSQL supports a powerful *rule system* for the specification of *views* and ambiguous *view updates*. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using *row level* processing and was implemented deep in the *executor*. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called *query rewriting*. The *rewrite system* is a module that exists between the *parser stage* and the *planner/optimizer*. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 36, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

## 43.5. Planner/Optimizer

The task of the *planner/optimizer* is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

**Note:** In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a *Genetic Query Optimizer* when the number of joins exceeds a threshold (see `geqo_threshold`).

The planner's search procedure actually works with data structures called *paths*, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged *plan tree* is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we'll ignore the distinction between paths and plans.

### 43.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPER constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPER` is one of the operators listed in the index's *operator class*, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query's `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- *nested loop join*: The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)

- *merge join*: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.
- *hash join*: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than `geqo_threshold` relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the `WHERE` qualification (i.e. for which a restriction like `where rel1.attr1=rel2.attr2` exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When `geqo_threshold` is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 49. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do *selection* (discarding rows that do not meet a specified boolean condition) and *projection* (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the `WHERE` clause and computation of required output expressions to the most appropriate nodes of the plan tree.

## 43.6. Executor

The *executor* takes the plan handed back by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a `MergeJoin` node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to `lefttree`). The new top node (the top node of the left subplan) is, let's say, a `Sort` node and again recursion is needed to obtain an input row. The child node of the `Sort` might be a `SeqScan` node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The `Sort` node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a `NULL` instead of a row), the `Sort` code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The `MergeJoin` node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the `MergeJoin` node returns `NULL` to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. For `SELECT`, the top-level executor code only needs to send each row returned by the query plan tree off to the client. For `INSERT`, each returned row is inserted into the target table specified for the `INSERT`. (A simple `INSERT . . . VALUES` command creates a trivial plan tree consisting of a single `Result` node, which computes just one result row. But `INSERT . . . SELECT` can demand the full power of the executor mechanism.) For `UPDATE`, the planner arranges that each computed row includes all the updated column values, plus the *TID* (tuple ID, or row ID) of the original target row; the executor top level uses this information to create a new updated row and mark the old row deleted. For `DELETE`, the only column that is actually returned by the plan is the TID, and the executor top level simply uses the TID to visit each target row and mark it deleted.

# Chapter 44. System Catalogs

The system catalogs are the place where a relational database management system stores schema meta-data, such as information about tables and columns, and internal bookkeeping information. PostgreSQL's system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are always SQL commands to do that. (For example, `CREATE DATABASE` inserts a row into the `pg_database` catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, such as adding index access methods.

## 44.1. Overview

Table 44-1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

**Table 44-1. System Catalogs**

Catalog Name	Purpose
<code>pg_aggregate</code>	aggregate functions
<code>pg_am</code>	index access methods
<code>pg_amop</code>	access method operators
<code>pg_amproc</code>	access method support procedures
<code>pg_attrdef</code>	column default values
<code>pg_attribute</code>	table columns (“attributes”)
<code>pg_authid</code>	authorization identifiers (roles)
<code>pg_auth_members</code>	authorization identifier membership relationships
<code>pg_autovacuum</code>	per-relation autovacuum configuration parameters
<code>pg_cast</code>	casts (data type conversions)
<code>pg_class</code>	tables, indexes, sequences, views (“relations”)
<code>pg_constraint</code>	check constraints, unique constraints, primary key constraints, foreign key constraints
<code>pg_conversion</code>	encoding conversion information
<code>pg_database</code>	databases within this database cluster
<code>pg_depend</code>	dependencies between database objects
<code>pg_description</code>	descriptions or comments on database objects
<code>pg_enum</code>	enum label and value definitions
<code>pg_index</code>	additional index information

Catalog Name	Purpose
pg_inherits	table inheritance hierarchy
pg_language	languages for writing functions
pg_largeobject	large objects
pg_listener	asynchronous notification support
pg_namespace	schemas
pg_opclass	access method operator classes
pg_operator	operators
pg_opfamily	access method operator families
pg_pltemplate	template data for procedural languages
pg_proc	functions and procedures
pg_rewrite	query rewrite rules
pg_shdepend	dependencies on shared objects
pg_shdescription	comments on shared objects
pg_statistic	planner statistics
pg_tablespace	tablespaces within this database cluster
pg_trigger	triggers
pg_ts_config	text search configurations
pg_ts_config_map	text search configurations' token mappings
pg_ts_dict	text search dictionaries
pg_ts_parser	text search parsers
pg_ts_template	text search templates
pg_type	data types

## 44.2. pg\_aggregate

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

**Table 44-2. `pg_aggregate` Columns**

Name	Type	References	Description
aggfnoid	regproc	pg_proc.oid	pg_proc OID of the aggregate function
aggtransfn	regproc	pg_proc.oid	Transition function

Name	Type	References	Description
aggfinalfn	regproc	pg_proc.oid	Final function (zero if none)
aggsortop	oid	pg_operator.oid	Associated sort operator (zero if none)
aggtranstype	oid	pg_type.oid	Data type of the aggregate function's internal transition (state) data
agginitval	text		The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL

New aggregate functions are registered with the *CREATE AGGREGATE* command. See Section 34.10 for more information about writing aggregate functions and the meaning of the transition functions, etc.

## 44.3. pg\_am

The catalog `pg_am` stores information about index access methods. There is one row for each index access method supported by the system. The contents of this catalog are discussed in detail in Chapter 50.

**Table 44-3. `pg_am` Columns**

Name	Type	References	Description
amname	name		Name of the access method
amstrategies	int2		Number of operator strategies for this access method, or zero if access method does not have a fixed set of operator strategies
amsupport	int2		Number of support routines for this access method
amcanorder	bool		Does the access method support ordered scans?

Name	Type	References	Description
amcanunique	bool		Does the access method support unique indexes?
amcanmulticol	bool		Does the access method support multicolumn indexes?
amoptionalkey	bool		Does the access method support a scan without any constraint for the first index column?
amindexnulls	bool		Does the access method support null index entries?
amsearchnulls	bool		Does the access method support IS NULL searches?
amstorage	bool		Can index storage data type differ from column data type?
amclusterable	bool		Can an index of this type be clustered on?
aminsert	regproc	pg_proc.oid	“Insert this tuple” function
ambeginscan	regproc	pg_proc.oid	“Start new scan” function
amgettupple	regproc	pg_proc.oid	“Next valid tuple” function
amgetmulti	regproc	pg_proc.oid	“Fetch multiple tuples” function
amrescan	regproc	pg_proc.oid	“Restart this scan” function
amendscan	regproc	pg_proc.oid	“End this scan” function
ammarkpos	regproc	pg_proc.oid	“Mark current scan position” function
amrestrpos	regproc	pg_proc.oid	“Restore marked scan position” function
ambuild	regproc	pg_proc.oid	“Build new index” function
ambulkdelete	regproc	pg_proc.oid	Bulk-delete function
amvacuumcleanup	regproc	pg_proc.oid	Post-VACUUM cleanup function

Name	Type	References	Description
amcostestimate	regproc	pg_proc.oid	Function to estimate cost of an index scan
amoptions	regproc	pg_proc.oid	Function to parse and validate <code>reloptions</code> for an index

## 44.4. pg\_amop

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. An operator can appear in more than one family, but cannot appear in more than one position within a family.

**Table 44-4. `pg_amop` Columns**

Name	Type	References	Description
amopfamily	oid	pg_opfamily.oid	The operator family this entry is for
amoplefttype	oid	pg_type.oid	Left-hand input data type of operator
amoprightright	oid	pg_type.oid	Right-hand input data type of operator
amopstrategy	int2		Operator strategy number
amopreqcheck	bool		Index hit must be rechecked
amopopr	oid	pg_operator.oid	OID of the operator
amopmethod	oid	pg_am.oid	Index access method operator family is for

An entry's `amopmethod` must match the `opfmeth` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprightright` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

## 44.5. pg\_amproc

The catalog `pg_amproc` stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

**Table 44-5. `pg_amproc` Columns**

Name	Type	References	Description
amprocfamily	oid	pg_opfamily.oid	The operator family this entry is for
amproclefttype	oid	pg_type.oid	Left-hand input data type of associated operator
amprocrighttype	oid	pg_type.oid	Right-hand input data type of associated operator
amprocnum	int2		Support procedure number
amproc	regproc	pg_proc.oid	OID of the procedure

The usual interpretation of the `amproclefttype` and `amprocrighttype` fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There is a notion of “default” support procedures for an index, which are those with `amproclefttype` and `amprocrighttype` both equal to the index `opclass`’s `opcintype`.

## 44.6. pg\_attrdef

The catalog `pg_attrdef` stores column default values. The main information about columns is stored in `pg_attribute` (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

**Table 44-6. `pg_attrdef` Columns**

Name	Type	References	Description
adrelid	oid	pg_class.oid	The table this column belongs to
adnum	int2	pg_attribute.attnum	The number of the column
adbin	text		The internal representation of the column default value
adsrc	text		A human-readable representation of the default value

The `adsrc` field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the `adbin` field (with `pg_get_expr` for example) is a better way to display the default value.

## 44.7. pg\_attribute

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

**Table 44-7. `pg_attribute` Columns**

Name	Type	References	Description
<code>attrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The table this column belongs to
<code>attname</code>	<code>name</code>		The column name
<code>atttypid</code>	<code>oid</code>	<code>pg_type.oid</code>	The data type of this column
<code>attstattarget</code>	<code>int4</code>		<code>attstattarget</code> controls the level of detail of statistics accumulated for this column by <i>ANALYZE</i> . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, <code>attstattarget</code> is both the target number of “most common values” to collect, and the target number of histogram bins to create
<code>attlen</code>	<code>int2</code>		A copy of <code>pg_type.typelen</code> of this column’s type

Name	Type	References	Description
<code>attnum</code>	<code>int2</code>		The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>oid</code> , have (arbitrary) negative numbers
<code>attdims</code>	<code>int4</code>		Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means “it’s an array”)
<code>attcacheoff</code>	<code>int4</code>		Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row
<code>atttypmod</code>	<code>int4</code>		<code>atttypmod</code> records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need <code>atttypmod</code>
<code>attbyval</code>	<code>bool</code>		A copy of <code>pg_type.typbyval</code> of this column’s type

Name	Type	References	Description
<code>attstorage</code>	<code>char</code>		Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy
<code>attalign</code>	<code>char</code>		A copy of <code>pg_type.typalign</code> of this column's type
<code>attnotnull</code>	<code>bool</code>		This represents a not-null constraint. It is possible to change this column to enable or disable the constraint
<code>atthasdef</code>	<code>bool</code>		This column has a default value, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the value
<code>attisdropped</code>	<code>bool</code>		This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL
<code>attislocal</code>	<code>bool</code>		This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously
<code>attinhcount</code>	<code>int4</code>		The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed

In a dropped column's `pg_attribute` entry, `atttypid` is reset to zero, but `attlen` and the other fields copied from `pg_type` are still valid. This arrangement is needed to cope with the situation where the

dropped column's data type was later dropped, and so there is no `pg_type` row anymore. `attlen` and the other fields can be used to interpret the contents of a row of the table.

## 44.8. `pg_authid`

The catalog `pg_authid` contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Chapter 19 contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

**Table 44-8. `pg_authid` Columns**

Name	Type	Description
<code>rolname</code>	<code>name</code>	Role name
<code>rolsuper</code>	<code>bool</code>	Role has superuser privileges
<code>rolinherit</code>	<code>bool</code>	Role automatically inherits privileges of roles it is a member of
<code>rolcreaterole</code>	<code>bool</code>	Role can create more roles
<code>rolcreatedb</code>	<code>bool</code>	Role can create databases
<code>rolcatupdate</code>	<code>bool</code>	Role can update system catalogs directly. (Even a superuser cannot do this unless this column is true)
<code>rolcanlogin</code>	<code>bool</code>	Role can log in. That is, this role can be given as the initial session authorization identifier
<code>rolconlimit</code>	<code>int4</code>	For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit
<code>rolpassword</code>	<code>text</code>	Password (possibly encrypted); NULL if none
<code>rolvaliduntil</code>	<code>timestampz</code>	Password expiry time (only used for password authentication); NULL if no expiration
<code>rolconfig</code>	<code>text[]</code>	Session defaults for run-time configuration variables

## 44.9. pg\_auth\_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

**Table 44-9. `pg_auth_members` Columns**

Name	Type	References	Description
<code>roleid</code>	<code>oid</code>	<code>pg_authid.oid</code>	ID of a role that has a member
<code>member</code>	<code>oid</code>	<code>pg_authid.oid</code>	ID of a role that is a member of <code>roleid</code>
<code>grantor</code>	<code>oid</code>	<code>pg_authid.oid</code>	ID of the role that granted this membership
<code>admin_option</code>	<code>bool</code>		True if <code>member</code> can grant membership in <code>roleid</code> to others

## 44.10. pg\_autovacuum

The catalog `pg_autovacuum` stores optional per-relation configuration parameters for the autovacuum daemon. If there is an entry here for a particular relation, the given parameters will be used for autovacuuming that table. If no entry is present, the system-wide defaults will be used. For more information about the autovacuum daemon, see Section 23.1.4.

**Note:** It is likely that `pg_autovacuum` will disappear in a future release, with the information instead being kept in `pg_class.reloptions` entries.

**Table 44-10. `pg_autovacuum` Columns**

Name	Type	References	Description
<code>vacrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The table this entry is for
<code>enabled</code>	<code>bool</code>		If false, this table will not be autovacuumed, except to prevent transaction ID wraparound

Name	Type	References	Description
<code>vac_base_thresh</code>	integer		Minimum number of modified tuples before vacuum
<code>vac_scale_factor</code>	float4		Multiplier for <code>reltuples</code> to add to <code>vac_base_thresh</code>
<code>anl_base_thresh</code>	integer		Minimum number of modified tuples before analyze
<code>anl_scale_factor</code>	float4		Multiplier for <code>reltuples</code> to add to <code>anl_base_thresh</code>
<code>vac_cost_delay</code>	integer		Custom <code>vacuum_cost_delay</code> parameter
<code>vac_cost_limit</code>	integer		Custom <code>vacuum_cost_limit</code> parameter
<code>freeze_min_age</code>	integer		Custom <code>vacuum_freeze_min_age</code> parameter
<code>freeze_max_age</code>	integer		Custom <code>autovacuum_freeze_max_age</code> parameter

The autovacuum daemon will initiate a `VACUUM` operation on a particular table when the number of updated or deleted tuples exceeds `vac_base_thresh` plus `vac_scale_factor` times the number of live tuples currently estimated to be in the relation. Similarly, it will initiate an `ANALYZE` operation when the number of inserted, updated or deleted tuples exceeds `anl_base_thresh` plus `anl_scale_factor` times the number of live tuples currently estimated to be in the relation.

Also, the autovacuum daemon will perform a `VACUUM` operation to prevent transaction ID wraparound if the table's `pg_class.relFrozenxid` field attains an age of more than `freeze_max_age` transactions, whether the table has been changed or not, even if `pg_autovacuum.enabled` is set to `false` for it. The system will launch autovacuum to perform such `VACUUMs` even if autovacuum is otherwise disabled. See Section 23.1.3 for more about wraparound prevention.

Any of the numerical fields can contain `-1` (or indeed any negative value) to indicate that the system-wide default should be used for this particular value. Observe that the `vac_cost_delay` variable inherits its default value from the `autovacuum_vacuum_cost_delay` configuration parameter, or from `vacuum_cost_delay` if the former is set to a negative value. The same applies to `vac_cost_limit`. Also, autovacuum will ignore attempts to set a per-table `freeze_max_age` larger than the system-wide setting (it can only be set smaller), and the `freeze_min_age` value will be limited to half the system-wide `autovacuum_freeze_max_age` setting. Note that while you can set `freeze_max_age` very small, or even zero, this is usually unwise since it will force frequent vacuuming.

## 44.11. pg\_cast

The catalog `pg_cast` stores data type conversion paths, both built-in paths and those defined with *CREATE CAST*.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “I/O conversion casts”, those performed using a data type’s own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

**Table 44-11. `pg_cast` Columns**

Name	Type	References	Description
<code>castsource</code>	<code>oid</code>	<code>pg_type.oid</code>	OID of the source data type
<code>casttarget</code>	<code>oid</code>	<code>pg_type.oid</code>	OID of the target data type
<code>castfunc</code>	<code>oid</code>	<code>pg_proc.oid</code>	The OID of the function to use to perform this cast. Zero is stored if the data types are binary compatible (that is, no run-time operation is needed to perform the cast)
<code>castcontext</code>	<code>char</code>		Indicates what contexts the cast can be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one

argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

## 44.12. `pg_class`

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences, views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

**Table 44-12. `pg_class` Columns**

Name	Type	References	Description
<code>relname</code>	<code>name</code>		Name of the table, index, view, etc.
<code>relnamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	The OID of the namespace that contains this relation
<code>reltype</code>	<code>oid</code>	<code>pg_type.oid</code>	The OID of the data type that corresponds to this table’s row type, if any (zero for indexes, which have no <code>pg_type</code> entry)
<code>relowner</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the relation
<code>relam</code>	<code>oid</code>	<code>pg_am.oid</code>	If this is an index, the access method used (B-tree, hash, etc.)
<code>relfilenode</code>	<code>oid</code>		Name of the on-disk file of this relation; 0 if none
<code>reltablespace</code>	<code>oid</code>	<code>pg_tablespace.oid</code>	The tablespace in which this relation is stored. If zero, the database’s default tablespace is implied. (Not meaningful if the relation has no on-disk file.)

Name	Type	References	Description
relpages	int4		Size of the on-disk representation of this table in pages (of size BLCKSZ). This is only an estimate used by the planner. It is updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX
reltuples	float4		Number of rows in the table. This is only an estimate used by the planner. It is updated by VACUUM, ANALYZE, and a few DDL commands such as CREATE INDEX
reltoastrelid	oid	pg_class.oid	OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes “out of line” in a secondary table
reltoastidxid	oid	pg_class.oid	For a TOAST table, the OID of its index. 0 if not a TOAST table
relhasindex	bool		True if this is a table and it has (or recently had) any indexes. This is set by CREATE INDEX, but not cleared immediately by DROP INDEX. VACUUM clears relhasindex if it finds the table has no indexes
relisshared	bool		True if this table is shared across all databases in the cluster. Only certain system catalogs (such as pg_database) are shared

Name	Type	References	Description
relkind	char		r = ordinary table, i = index, s = sequence, v = view, c = composite type, t = TOAST table
relnatts	int2		Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> . See also <code>pg_attribute.attnum</code>
relchecks	int2		Number of check constraints on the table; see <code>pg_constraint</code> catalog
reltriggers	int2		Number of triggers on the table; see <code>pg_trigger</code> catalog
relukeys	int2		Unused ( <i>not</i> the number of unique keys)
relfkeys	int2		Unused ( <i>not</i> the number of foreign keys on the table)
relrefs	int2		Unused
relhasoids	bool		True if we generate an OID for each row of the relation
relhaspkey	bool		True if the table has (or once had) a primary key
relhasrules	bool		True if table has rules; see <code>pg_rewrite</code> catalog
relhassubclass	bool		True if table has (or once had) any inheritance children

Name	Type	References	Description
relfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_clog</code> to be shrunk. Zero ( <code>InvalidTransactionId</code> ) if the relation is not a table
relacl	aclitem[]		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details
reloptions	text[]		Access-method-specific options, as “keyword=value” strings

## 44.13. pg\_constraint

The catalog `pg_constraint` stores check, primary key, unique, and foreign key constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the `pg_attribute` catalog.

Check constraints on domains are stored here, too.

**Table 44-13. `pg_constraint` Columns**

Name	Type	References	Description
conname	name		Constraint name (not necessarily unique!)
connamespace	oid	<code>pg_namespace.oid</code>	The OID of the namespace that contains this constraint

Name	Type	References	Description
contype	char		c = check constraint, f = foreign key constraint, p = primary key constraint, u = unique constraint
condeferrable	bool		Is the constraint deferrable?
condeferred	bool		Is the constraint deferred by default?
conrelid	oid	pg_class.oid	The table this constraint is on; 0 if not a table constraint
contypid	oid	pg_type.oid	The domain this constraint is on; 0 if not a domain constraint
confrelid	oid	pg_class.oid	If a foreign key, the referenced table; else 0
confupdtype	char		Foreign key update action code
confdeltype	char		Foreign key deletion action code
confmatchtype	char		Foreign key match type
conkey	int2[]	pg_attribute.attnum	If a table constraint, list of columns which the constraint constrains
confkey	int2[]	pg_attribute.attnum	If a foreign key, list of the referenced columns
conpfeqop	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for PK = FK comparisons
conppeqop	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for PK = PK comparisons
conffeqop	oid[]	pg_operator.oid	If a foreign key, list of the equality operators for FK = FK comparisons
conbin	text		If a check constraint, an internal representation of the expression

Name	Type	References	Description
<code>consrc</code>	text		If a check constraint, a human-readable representation of the expression

**Note:** `consrc` is not updated when referenced objects change; for example, it won't track renaming of columns. Rather than relying on this field, it's best to use `pg_get_constraintdef()` to extract the definition of a check constraint.

**Note:** `pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

## 44.14. `pg_conversion`

The catalog `pg_conversion` describes the available encoding conversion procedures. See *CREATE CONVERSION* for more information.

**Table 44-14. `pg_conversion` Columns**

Name	Type	References	Description
<code>conname</code>	name		Conversion name (unique within a namespace)
<code>connamespace</code>	oid	<code>pg_namespace.oid</code>	The OID of the namespace that contains this conversion
<code>conowner</code>	oid	<code>pg_authid.oid</code>	Owner of the conversion
<code>conforencoding</code>	int4		Source encoding ID
<code>contoencoding</code>	int4		Destination encoding ID
<code>conproc</code>	regproc	<code>pg_proc.oid</code>	Conversion procedure
<code>condefault</code>	bool		True if this is the default conversion

## 44.15. `pg_database`

The catalog `pg_database` stores information about the available databases. Databases are created with

the `CREATE DATABASE` command. Consult Chapter 20 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 44-15. `pg_database` Columns**

Name	Type	References	Description
<code>datname</code>	<code>name</code>		Database name
<code>datdba</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the database, usually the user who created it
<code>encoding</code>	<code>int4</code>		Character encoding for this database ( <code>pg_encoding_to_char()</code> can translate this number to the encoding name)
<code>datistemplate</code>	<code>bool</code>		If true then this database can be used in the <code>TEMPLATE</code> clause of <code>CREATE DATABASE</code> to create a new database as a clone of this one
<code>dataallowconn</code>	<code>bool</code>		If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered
<code>datconnlimit</code>	<code>int4</code>		Sets maximum number of concurrent connections that can be made to this database. -1 means no limit
<code>datlastsysoid</code>	<code>oid</code>		Last system OID in the database; useful particularly to <code>pg_dump</code>

Name	Type	References	Description
<code>datfrozenxid</code>	<code>xid</code>		All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_clog</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relfrozenxid</code> values
<code>dattablespace</code>	<code>oid</code>	<code>pg_tablespace.oid</code>	The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there
<code>datconfig</code>	<code>text[]</code>		Session defaults for run-time configuration variables
<code>datacl</code>	<code>aclitem[]</code>		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details

## 44.16. `pg_depend`

The catalog `pg_depend` records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case.

See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a database cluster.

**Table 44-16. `pg_depend` Columns**

Name	Type	References	Description
classid	oid	pg_class.oid	The OID of the system catalog the dependent object is in
objid	oid	any OID column	The OID of the specific dependent object
objsubid	int4		For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero
refclassid	oid	pg_class.oid	The OID of the system catalog the referenced object is in
refobjid	oid	any OID column	The OID of the specific referenced object
refobjsubid	int4		For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_depend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

#### DEPENDENCY\_NORMAL (n)

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

#### DEPENDENCY\_AUTO (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

**DEPENDENCY\_INTERNAL (i)**

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. Example: a trigger that's created to enforce a foreign-key constraint is made internally dependent on the constraint's `pg_constraint` entry.

**DEPENDENCY\_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

## 44.17. `pg_description`

The catalog `pg_description` stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`.

See also `pg_shdescription`, which performs a similar function for descriptions involving objects that are shared across a database cluster.

**Table 44-17. `pg_description` Columns**

Name	Type	References	Description
<code>objoid</code>	<code>oid</code>	any OID column	The OID of the object this description pertains to
<code>classoid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the system catalog this object appears in
<code>objsubid</code>	<code>int4</code>		For a comment on a table column, this is the column number (the <code>objoid</code> and <code>classoid</code> refer to the table itself). For all other object types, this column is zero
<code>description</code>	<code>text</code>		Arbitrary text that serves as the description of this object

## 44.18. pg\_enum

The `pg_enum` catalog contains entries matching enum types to their associated values and labels. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. The OIDs for a particular enum type are guaranteed to be ordered in the way the type should sort, but there is no guarantee about the ordering of OIDs of unrelated enum types.

**Table 44-18. `pg_enum` Columns**

Name	Type	References	Description
<code>enumtypid</code>	<code>oid</code>	<code>pg_type.oid</code>	The OID of the <code>pg_type</code> entry owning this enum value
<code>enumlabel</code>	<code>name</code>		The textual label for this enum value

## 44.19. pg\_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

**Table 44-19. `pg_index` Columns**

Name	Type	References	Description
<code>indexrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the <code>pg_class</code> entry for this index
<code>indrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the <code>pg_class</code> entry for the table this index is for
<code>indnatts</code>	<code>int2</code>		The number of columns in the index (duplicates <code>pg_class.relnatts</code> )
<code>indisunique</code>	<code>bool</code>		If true, this is a unique index
<code>indisprimary</code>	<code>bool</code>		If true, this index represents the primary key of the table ( <code>indisunique</code> should always be true when this is true)
<code>indisclustered</code>	<code>bool</code>		If true, the table was last clustered on this index

Name	Type	References	Description
<code>indisvalid</code>	<code>bool</code>		If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not true either
<code>indcheckxmin</code>	<code>bool</code>		If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incompatible rows that they can see
<code>indisready</code>	<code>bool</code>		If true, the index is currently ready for inserts. False means the index must be ignored by <code>INSERT/UPDATE</code> operations
<code>indkey</code>	<code>int2vector</code>	<code>pg_attribute.attnum</code>	This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example a value of <code>1 3</code> would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference

Name	Type	References	Description
indclass	oidvector	pg_opclass.oid	For each column in the index key, this contains the OID of the operator class to use. See pg_opclass for details
indoption	int2vector		This is an array of indnatts values that store per-column flag bits. The meaning of the bits is defined by the index's access method
indexprs	text		Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in indkey. NULL if all index attributes are simple references
indpred	text		Expression tree (in nodeToString() representation) for partial index predicate. NULL if not a partial index

## 44.20. pg\_inherits

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

**Table 44-20. `pg_inherits` Columns**

Name	Type	References	Description
inhrelid	oid	pg_class.oid	The OID of the child table
inhparent	oid	pg_class.oid	The OID of the parent table

Name	Type	References	Description
inhseqno	int4		If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1

## 44.21. pg\_language

The catalog `pg_language` registers languages in which you can write functions or stored procedures. See *CREATE LANGUAGE* and Chapter 37 for more information about language handlers.

**Table 44-21. pg\_language Columns**

Name	Type	References	Description
lanname	name		Name of the language
lanowner	oid	pg_authid.oid	Owner of the language
lanispl	bool		This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future
lanpltrusted	bool		True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages

Name	Type	References	Description
lanplcallfoid	oid	pg_proc.oid	For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language
lanvalidator	oid	pg_proc.oid	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided
lanacl	aclitem[]		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details

## 44.22. pg\_largeobject

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

**Table 44-22. `pg_largeobject` Columns**

Name	Type	Description
loid	oid	Identifier of the large object that includes this page
pageno	int4	Page number of this page within its large object (counting from zero)
data	bytea	Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno * LOBLKSIZE`) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions

within a large object read as zeroes.

## 44.23. pg\_listener

The catalog `pg_listener` supports the *LISTEN* and *NOTIFY* commands. A listener creates an entry in `pg_listener` for each notification name it is listening for. A notifier scans `pg_listener` and updates each matching entry to show that a notification has occurred. The notifier also sends a signal (using the PID recorded in the table) to awaken the listener from sleep.

**Table 44-23. `pg_listener` Columns**

Name	Type	References	Description
<code>relname</code>	<code>name</code>	Notify condition name. (The name need not match any actual relation in the database; the name <code>relname</code> is historical.)	
<code>listenerpid</code>	<code>int4</code>	PID of the server process that created this entry	
<code>notification</code>	<code>int4</code>	Zero if no event is pending for this listener. If an event is pending, the PID of the server process that sent the notification	

## 44.24. pg\_namespace

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

**Table 44-24. `pg_namespace` Columns**

Name	Type	References	Description
<code>nspname</code>	<code>name</code>		Name of the namespace
<code>nspowner</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the namespace
<code>nspacl</code>	<code>aclitem[]</code>		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details

## 44.25. pg\_opclass

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column's data type as their lefthand input.

Operator classes are described at length in Section 34.14.

**Table 44-25. `pg_opclass` Columns**

Name	Type	References	Description
<code>opcmethod</code>	<code>oid</code>	<code>pg_am.oid</code>	Index access method operator class is for
<code>opcname</code>	<code>name</code>		Name of this operator class
<code>opcnamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	Namespace of this operator class
<code>opcowner</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the operator class
<code>opcfamily</code>	<code>oid</code>	<code>pg_opfamily.oid</code>	Operator family containing the operator class
<code>opcintype</code>	<code>oid</code>	<code>pg_type.oid</code>	Data type that the operator class indexes
<code>opcdefault</code>	<code>bool</code>		True if this operator class is the default for <code>opcintype</code>
<code>opckeytype</code>	<code>oid</code>	<code>pg_type.oid</code>	Type of data stored in index, or zero if same as <code>opcintype</code>

An operator class's `opcmethod` must match the `opfmeth` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

## 44.26. pg\_operator

The catalog `pg_operator` stores information about operators. See *CREATE OPERATOR* and Section 34.12 for more information.

**Table 44-26. `pg_operator` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
<code>oprname</code>	name		Name of the operator
<code>oprnamespace</code>	oid	<code>pg_namespace.oid</code>	The OID of the namespace that contains this operator
<code>oprowner</code>	oid	<code>pg_authid.oid</code>	Owner of the operator
<code>oprkind</code>	char		b = infix (“both”), l = prefix (“left”), r = postfix (“right”)
<code>oprcanmerge</code>	bool		This operator supports merge joins
<code>oprcanhash</code>	bool		This operator supports hash joins
<code>oprleft</code>	oid	<code>pg_type.oid</code>	Type of the left operand
<code>oprright</code>	oid	<code>pg_type.oid</code>	Type of the right operand
<code>oprresult</code>	oid	<code>pg_type.oid</code>	Type of the result
<code>oprcom</code>	oid	<code>pg_operator.oid</code>	Commutator of this operator, if any
<code>oprnegate</code>	oid	<code>pg_operator.oid</code>	Negator of this operator, if any
<code>oprcode</code>	regproc	<code>pg_proc.oid</code>	Function that implements this operator
<code>oprrest</code>	regproc	<code>pg_proc.oid</code>	Restriction selectivity estimation function for this operator
<code>oprjoin</code>	regproc	<code>pg_proc.oid</code>	Join selectivity estimation function for this operator

Unused column contain zeroes. For example, `oprleft` is zero for a prefix operator.

## 44.27. `pg_opfamily`

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 34.14.

**Table 44-27. pg\_opfamily Columns**

Name	Type	References	Description
opfmethod	oid	pg_am.oid	Index access method operator family is for
opfname	name		Name of this operator family
opfnamespace	oid	pg_namespace.oid	Namespace of this operator family
opfowner	oid	pg_authid.oid	Owner of the operator family

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

## 44.28. pg\_pltemplate

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

**Table 44-28. pg\_pltemplate Columns**

Name	Type	Description
tmplname	name	Name of the language this template is for
tmpltrusted	boolean	True if language is considered trusted
tmpldbacreate	boolean	True if language may be created by a database owner
tmplhandler	text	Name of call handler function
tmplvalidator	text	Name of validator function, or NULL if none
tmpllibrary	text	Path of shared library that implements language
tmplacl	aclitem[]	Access privileges for template (not yet used)

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands. It is likely that a future release of PostgreSQL will offer commands to change the entries in a cleaner

fashion.

When implemented, the `tmplacl` field will provide access control for the template itself (i.e., the right to create a language using it), not for the languages created from the template.

## 44.29. `pg_proc`

The catalog `pg_proc` stores information about functions (or procedures). See *CREATE FUNCTION* and Section 34.3 for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

**Table 44-29. `pg_proc` Columns**

Name	Type	References	Description
<code>proname</code>	<code>name</code>		Name of the function
<code>pronamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	The OID of the namespace that contains this function
<code>proowner</code>	<code>oid</code>	<code>pg_authid.oid</code>	Owner of the function
<code>prolang</code>	<code>oid</code>	<code>pg_language.oid</code>	Implementation language or call interface of this function
<code>procost</code>	<code>float4</code>		Estimated execution cost (in units of <code>cpu_operator_cost</code> ); if <code>proretset</code> , this is cost per row returned
<code>prorows</code>	<code>float4</code>		Estimated number of result rows (zero if not <code>proretset</code> )
<code>proisagg</code>	<code>bool</code>		Function is an aggregate function
<code>prosecdef</code>	<code>bool</code>		Function is a security definer (i.e., a “setuid” function)

Name	Type	References	Description
<code>proisstrict</code>	<code>bool</code>		Function returns null if any call argument is null. In that case the function won't actually be called at all. Functions that are not "strict" must be prepared to handle null inputs
<code>proretset</code>	<code>bool</code>		Function returns a set (i.e., multiple values of the specified data type)
<code>provolatile</code>	<code>char</code>		<code>provolatile</code> tells whether the function's result depends only on its input arguments, or is affected by outside factors. It is <code>i</code> for "immutable" functions, which always deliver the same result for the same inputs. It is <code>s</code> for "stable" functions, whose results (for fixed inputs) do not change within a scan. It is <code>v</code> for "volatile" functions, whose results might change at any time. (Use <code>v</code> also for functions with side-effects, so that calls to them cannot get optimized away.)
<code>pronargs</code>	<code>int2</code>		Number of arguments
<code>prorettype</code>	<code>oid</code>	<code>pg_type.oid</code>	Data type of the return value
<code>proargtypes</code>	<code>oidvector</code>	<code>pg_type.oid</code>	An array with the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> arguments), and thus represents the call signature of the function

Name	Type	References	Description
<code>proallargtypes</code>	<code>oid[]</code>	<code>pg_type.oid</code>	An array with the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0
<code>proargmodes</code>	<code>char[]</code>		An array with the modes of the function arguments, encoded as <code>i</code> for <code>IN</code> arguments, <code>o</code> for <code>OUT</code> arguments, <code>b</code> for <code>INOUT</code> arguments. If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code>
<code>proargnames</code>	<code>text[]</code>		An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code>

Name	Type	References	Description
<code>prosrc</code>	<code>text</code>		This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention
<code>probin</code>	<code>bytea</code>		Additional information about how to invoke the function. Again, the interpretation is language-specific
<code>proconfig</code>	<code>text[]</code>		Function's local settings for run-time configuration variables
<code>proacl</code>	<code>aclitem[]</code>		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

## 44.30. `pg_rewrite`

The catalog `pg_rewrite` stores rewrite rules for tables and views.

**Table 44-30. `pg_rewrite` Columns**

Name	Type	References	Description
<code>rulename</code>	<code>name</code>		Rule name
<code>ev_class</code>	<code>oid</code>	<code>pg_class.oid</code>	The table this rule is for
<code>ev_attr</code>	<code>int2</code>		The column this rule is for (currently, always zero to indicate the whole table)

Name	Type	References	Description
ev_type	char		Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE
ev_enabled	char		Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.
is_instead	bool		True if the rule is an INSTEAD rule
ev_qual	text		Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule’s qualifying condition
ev_action	text		Query tree (in the form of a <code>nodeToString()</code> representation) for the rule’s action

**Note:** `pg_class.relhasrules` must be true if a table has any rules in this catalog.

## 44.31. pg\_shdepend

The catalog `pg_shdepend` records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, `pg_shdepend` is shared across all databases of a cluster: there is only one copy of `pg_shdepend` per cluster, not one per database.

**Table 44-31. `pg_shdepend` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
dbid	oid	pg_database.oid	The OID of the database the dependent object is in, or zero for a shared object
classid	oid	pg_class.oid	The OID of the system catalog the dependent object is in
objid	oid	any OID column	The OID of the specific dependent object
refclassid	oid	pg_class.oid	The OID of the system catalog the referenced object is in (must be a shared catalog)
refobjid	oid	any OID column	The OID of the specific referenced object
deptype	char		A code defining the specific semantics of this dependency relationship; see text

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

`SHARED_DEPENDENCY_OWNER` (o)

The referenced object (which must be a role) is the owner of the dependent object.

`SHARED_DEPENDENCY_ACL` (a)

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

`SHARED_DEPENDENCY_PIN` (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.

## 44.32. pg\_shdescription

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 44-32. `pg_shdescription` Columns**

Name	Type	References	Description
<code>objoid</code>	<code>oid</code>	any OID column	The OID of the object this description pertains to
<code>classoid</code>	<code>oid</code>	<code>pg_class.oid</code>	The OID of the system catalog this object appears in
<code>description</code>	<code>text</code>		Arbitrary text that serves as the description of this object

## 44.33. `pg_statistic`

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query planner. There is one entry for each table column that has been analyzed. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column.

Since different kinds of statistics might be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see `src/include/catalog/pg_statistic.h`.

`pg_statistic` should not be readable by the public, since even statistical information about a table’s contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Table 44-33. `pg_statistic` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
starelid	oid	pg_class.oid	The table or index that the described column belongs to
staattnum	int2	pg_attribute.attnum	The number of the described column
stanullfrac	float4		The fraction of the column's entries that are null
stawidth	int4		The average stored width, in bytes, of nonnull entries
stadistinct	float4		The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a fraction of the number of rows in the table (for example, a column in which values appear about twice on the average could be represented by <code>stadistinct = -0.5</code> ). A zero value means the number of distinct values is unknown
stakindN	int2		A code number indicating the kind of statistics stored in the Nth "slot" of the <code>pg_statistic</code> row
staopN	oid	pg_operator.oid	An operator used to derive the statistics stored in the Nth "slot". For example, a histogram slot would show the < operator that defines the sort order of the data

Name	Type	References	Description
stanumbers $N$	float4[]		Numerical statistics of the appropriate kind for the $N$ th “slot”, or NULL if the slot kind does not involve numerical values
stavalues $N$	anyarray		Column data values of the appropriate kind for the $N$ th “slot”, or NULL if the slot kind does not store any data values. Each array’s element values are actually of the specific column’s data type, so there is no way to define these columns’ type more specifically than <code>anyarray</code>

## 44.34. pg\_tablespace

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

**Table 44-34. `pg_tablespace` Columns**

Name	Type	References	Description
spcname	name		Tablespace name
spcowner	oid	<code>pg_authid.oid</code>	Owner of the tablespace, usually the user who created it
spclocation	text		Location (directory path) of the tablespace
spcacl	aclitem[]		Access privileges; see <i>GRANT</i> and <i>REVOKE</i> for details

## 44.35. pg\_trigger

The catalog `pg_trigger` stores triggers on tables. See *CREATE TRIGGER* for more information.

**Table 44-35. `pg_trigger` Columns**

Name	Type	References	Description
<code>tgrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The table this trigger is on
<code>tgname</code>	<code>name</code>		Trigger name (must be unique among triggers of same table)
<code>tgfoid</code>	<code>oid</code>	<code>pg_proc.oid</code>	The function to be called
<code>tgtype</code>	<code>int2</code>		Bit mask identifying trigger conditions
<code>tgenabled</code>	<code>char</code>		Controls in which session_replication_role modes the trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always.
<code>tgisconstraint</code>	<code>bool</code>		True if trigger is a “constraint trigger”
<code>tgconstrname</code>	<code>name</code>		Constraint name, if a constraint trigger
<code>tgconstrrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	The table referenced by a referential integrity constraint
<code>tgconstraint</code>	<code>oid</code>	<code>pg_constraint.oid</code>	The <code>pg_constraint</code> entry owning the trigger, if any
<code>tgdeferrable</code>	<code>bool</code>		True if constraint trigger is deferrable
<code>tginitdeferred</code>	<code>bool</code>		True if constraint trigger is initially deferred
<code>tgnargs</code>	<code>int2</code>		Number of argument strings passed to trigger function
<code>tgattr</code>	<code>int2vector</code>		Currently unused

Name	Type	References	Description
tgargs	bytea		Argument strings to pass to trigger, each NULL-terminated

**Note:** When `tgconstraint` is nonzero, `tgisconstraint` must be true, and `tgconstrname`, `tgconstrrelid`, `tgdeferrable`, `tginitdeferred` are redundant with the referenced `pg_constraint` entry. The reason we keep these fields is that we support “stand-alone” constraint triggers with no corresponding `pg_constraint` entry.

**Note:** `pg_class.reltriggers` needs to agree with the number of triggers found in this table for each relation.

## 44.36. `pg_ts_config`

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`.

PostgreSQL’s text search features are described at length in Chapter 12.

**Table 44-36. `pg_ts_config` Columns**

Name	Type	References	Description
cfgrname	name		Text search configuration name
cfgrnamespace	oid	<code>pg_namespace.oid</code>	The OID of the namespace that contains this configuration
cfgrowner	oid	<code>pg_authid.oid</code>	Owner of the configuration
cfgrparser	oid	<code>pg_ts_parser.oid</code>	The OID of the text search parser for this configuration

## 44.37. `pg_ts_config_map`

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 44-37. `pg_ts_config_map` Columns**

Name	Type	References	Description
mapcfg	oid	<code>pg_ts_config.oid</code>	The OID of the <code>pg_ts_config</code> entry owning this map entry
maptokentype	integer		A token type emitted by the configuration's parser
mapseqno	integer		Order in which to consult this entry (lower <code>mapseqnos</code> first)
mapdict	oid	<code>pg_ts_dict.oid</code>	The OID of the text search dictionary to consult

## 44.38. `pg_ts_dict`

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 44-38. `pg_ts_dict` Columns**

Name	Type	References	Description
dictname	name		Text search dictionary name
dictnamespace	oid	<code>pg_namespace.oid</code>	The OID of the namespace that contains this dictionary
dictowner	oid	<code>pg_authid.oid</code>	Owner of the dictionary
dicttemplate	oid	<code>pg_ts_template.oid</code>	The OID of the text search template for this dictionary
dictinitoption	text		Initialization option string for the template

## 44.39. pg\_ts\_parser

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 44-39. `pg_ts_parser` Columns**

Name	Type	References	Description
<code>prsname</code>	<code>name</code>		Text search parser name
<code>prsnamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	The OID of the namespace that contains this parser
<code>prsstart</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the parser's startup function
<code>prstoken</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the parser's next-token function
<code>prsend</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the parser's shutdown function
<code>prsheadline</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the parser's headline function
<code>prslextype</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the parser's lextype function

## 44.40. pg\_ts\_template

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL's text search features are described at length in Chapter 12.

**Table 44-40. `pg_ts_template` Columns**

Name	Type	References	Description
<code>tplname</code>	<code>name</code>		Text search template name
<code>tplnamespace</code>	<code>oid</code>	<code>pg_namespace.oid</code>	The OID of the namespace that contains this template
<code>tplinit</code>	<code>regproc</code>	<code>pg_proc.oid</code>	OID of the template's initialization function

Name	Type	References	Description
tmpllexize	regproc	pg_proc.oid	OID of the template's lexize function

## 44.41. pg\_type

The catalog `pg_type` stores information about data types. Base types (scalar types) are created with *CREATE TYPE*, and domains with *CREATE DOMAIN*. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with *CREATE TYPE AS*.

**Table 44-41. `pg_type` Columns**

Name	Type	References	Description
typname	name		Data type name
typnamespace	oid	pg_namespace.oid	The OID of the namespace that contains this type
typowner	oid	pg_authid.oid	Owner of the type
typlen	int2		For a fixed-size type, <code>typlen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typlen</code> is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.

Name	Type	References	Description
<code>typbyval</code>	<code>bool</code>		<code>typbyval</code> determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typflen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value; this is currently true for type <code>float4</code> , for example
<code>typtype</code>	<code>char</code>		<code>typtype</code> is <code>b</code> for a base type, <code>c</code> for a composite type (e.g., a table's row type), <code>d</code> for a domain, <code>e</code> for an enum type, or <code>p</code> for a pseudo-type. See also <code>typrelid</code> and <code>typbasetype</code>
<code>typisdefined</code>	<code>bool</code>		True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When <code>typisdefined</code> is false, nothing except the type name, namespace, and OID can be relied on
<code>typdelim</code>	<code>char</code>		Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type

Name	Type	References	Description
<code>typrelid</code>	<code>oid</code>	<code>pg_class.oid</code>	If this is a composite type (see <code>typtype</code> ), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the <code>pg_class</code> entry doesn't really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link to.) Zero for non-composite types
<code>typelem</code>	<code>oid</code>	<code>pg_type.oid</code>	If <code>typelem</code> is not 0 then it identifies another row in <code>pg_type</code> . The current type can then be subscripted like an array yielding values of type <code>typelem</code> . A "true" array type is variable length ( <code>typlen = -1</code> ), but some fixed-length ( <code>typlen &gt; 0</code> ) types also have nonzero <code>typelem</code> , for example <code>name</code> and <code>point</code> . If a fixed-length type has a <code>typelem</code> then its internal representation must be some number of values of the <code>typelem</code> data type with no other data. Variable-length array types have a header defined by the array subroutines
<code>typarray</code>	<code>oid</code>	<code>pg_type.oid</code>	If <code>typarray</code> is not 0 then it identifies another row in <code>pg_type</code> , which is the "true" array type having this type as element

Name	Type	References	Description
typinput	regproc	pg_proc.oid	Input conversion function (text format)
typoutput	regproc	pg_proc.oid	Output conversion function (text format)
typreceive	regproc	pg_proc.oid	Input conversion function (binary format), or 0 if none
typsend	regproc	pg_proc.oid	Output conversion function (binary format), or 0 if none
typmodin	regproc	pg_proc.oid	Type modifier input function, or 0 if type does not support modifiers
typmodout	regproc	pg_proc.oid	Type modifier output function, or 0 to use the standard format
typanalyze	regproc	pg_proc.oid	Custom ANALYZE function, or 0 to use the standard function

Name	Type	References	Description
<code>typalign</code>	<code>char</code>		<p><code>typalign</code> is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:</p> <ul style="list-style-type: none"> <li>• <code>c</code> = <code>char</code> alignment, i.e., no alignment needed.</li> <li>• <code>s</code> = <code>short</code> alignment (2 bytes on most machines).</li> <li>• <code>i</code> = <code>int</code> alignment (4 bytes on most machines).</li> <li>• <code>d</code> = <code>double</code> alignment (8 bytes on many machines, but by no means all).</li> </ul> <p><b>Note:</b> For types used in system tables, it is critical that the size and alignment defined in <code>pg_type</code> agree with the way that the compiler will lay out the column in a structure representing a table row.</p>

Name	Type	References	Description
typstorage	char		<p>typstorage tells for varlena types (those with typplen = -1) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are</p> <ul style="list-style-type: none"> <li>• p: Value must always be stored plain.</li> <li>• e: Value can be stored in a “secondary” relation (if relation has one, see pg_class.reltoastrelid).</li> <li>• m: Value can be stored compressed inline.</li> <li>• x: Value can be stored compressed inline or stored in “secondary” storage.</li> </ul> <p>Note that m columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first).</p>
typnotnull	bool		typnotnull represents a not-null constraint on a type. Used for domains only
typbasetype	oid	pg_type.oid	If this is a domain (see typtype), then typbasetype identifies the type that this one is based on. Zero if this type is not a domain

Name	Type	References	Description
<code>typtypmod</code>	<code>int4</code>		Domains use <code>typtypmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code> ). -1 if this type is not a domain
<code>typndims</code>	<code>int4</code>		<code>typndims</code> is the number of array dimensions for a domain that is an array (that is, <code>typbasetype</code> is an array type; the domain's <code>typelem</code> will match the base type's <code>typelem</code> ). Zero for types other than domains over array types
<code>typdefaultbin</code>	<code>text</code>		If <code>typdefaultbin</code> is not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains
<code>typdefault</code>	<code>text</code>		<code>typdefault</code> is null if the type has no associated default value. If <code>typdefaultbin</code> is not null, <code>typdefault</code> must contain a human-readable version of the default expression represented by <code>typdefaultbin</code> . If <code>typdefaultbin</code> is null and <code>typdefault</code> is not, then <code>typdefault</code> is the external representation of the type's default value, which might be fed to the type's input converter to produce a constant

## 44.42. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 33) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it's usually better to use the information schema if it provides all the information you need.

Table 44-42 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 26-1.

Except where noted, all the views described here are read-only.

**Table 44-42. System Views**

View Name	Purpose
<code>pg_cursors</code>	open cursors
<code>pg_group</code>	groups of database users
<code>pg_indexes</code>	indexes
<code>pg_locks</code>	currently held locks
<code>pg_prepared_statements</code>	prepared statements
<code>pg_prepared_xacts</code>	prepared transactions
<code>pg_roles</code>	database roles
<code>pg_rules</code>	rules
<code>pg_settings</code>	parameter settings
<code>pg_shadow</code>	database users
<code>pg_stats</code>	planner statistics
<code>pg_tables</code>	tables
<code>pg_timezone_abbrevs</code>	time zone abbreviations
<code>pg_timezone_names</code>	time zone names
<code>pg_user</code>	database users
<code>pg_views</code>	views

## 44.43. `pg_cursors`

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the *DECLARE* statement in SQL

- via the Bind message in the frontend/backend protocol, as described in Section 45.2.3
- via the Server Programming Interface (SPI), as described in Section 42.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

**Table 44-43. `pg_cursors` Columns**

Name	Type	Description
<code>name</code>	<code>text</code>	The name of the cursor
<code>statement</code>	<code>text</code>	The verbatim query string submitted to declare this cursor
<code>is_holdable</code>	<code>boolean</code>	<code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise
<code>is_binary</code>	<code>boolean</code>	<code>true</code> if the cursor was declared <code>BINARY</code> ; <code>false</code> otherwise
<code>is_scrollable</code>	<code>boolean</code>	<code>true</code> if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise
<code>creation_time</code>	<code>timestampz</code>	The time at which the cursor was declared

The `pg_cursors` view is read only.

## 44.44. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

**Table 44-44. `pg_group` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
groname	name	pg_authid.rolname	Name of the group
grosysid	oid	pg_authid.oid	ID of this group
grolist	oid[]	pg_authid.oid	An array containing the IDs of the roles in this group

## 44.45. pg\_indexes

The view `pg_indexes` provides access to useful information about each index in the database.

**Table 44-45. `pg_indexes` Columns**

Name	Type	References	Description
schemaname	name	pg_namespace.nspname	Name of schema containing table and index
tablename	name	pg_class.relname	Name of table the index is for
indexname	name	pg_class.relname	Name of index
tablespace	name	pg_tablespace.spcname	Name of tablespace containing index (NULL if default for database)
indexdef	text		Index definition (a reconstructed <code>CREATE INDEX</code> command)

## 44.46. pg\_locks

The view `pg_locks` provides access to information about the locks held by open transactions within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object might appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object.

**Table 44-46. `pg_locks` Columns**

Name	Type	References	Description
locktype	text		type of the lockable object: relation, extend, page, tuple, transactionid, virtualxid, object, userlock, or advisory
database	oid	pg_database.oid	OID of the database in which the object exists, or zero if the object is a shared object, or NULL if the object is a transaction ID
relation	oid	pg_class.oid	OID of the relation, or NULL if the object is not a relation or part of a relation
page	integer		Page number within the relation, or NULL if the object is not a tuple or relation page
tuple	smallint		Tuple number within the page, or NULL if the object is not a tuple
virtualxid	text		Virtual ID of a transaction, or NULL if the object is not a virtual transaction ID
transactionid	xid		ID of a transaction, or NULL if the object is not a transaction ID
classid	oid	pg_class.oid	OID of the system catalog containing the object, or NULL if the object is not a general database object
objid	oid	any OID column	OID of the object within its system catalog, or NULL if the object is not a general database object

Name	Type	References	Description
objsubid	smallint		For a table column, this is the column number (the <code>classid</code> and <code>objid</code> refer to the table itself). For all other object types, this column is zero. NULL if the object is not a general database object
virtualtransaction	text		Virtual ID of the transaction that is holding or awaiting this lock
pid	integer		Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction
mode	text		Name of the lock mode held or desired by this process (see Section 13.3.1)
granted	boolean		True if lock is held, false if lock is awaited

`granted` is true in a row representing a lock held by the indicated transaction. False indicates that this transaction is currently waiting to acquire this lock, which implies that some other transaction is holding a conflicting lock mode on the same lockable object. The waiting transaction will sleep until the other lock is released (or a deadlock situation is detected). A single transaction can be waiting to acquire at most one lock at a time.

Every transaction holds an exclusive lock on its virtual transaction ID for its entire duration. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on its permanent transaction ID until it ends. When one transaction finds it necessary to wait specifically for another transaction, it does so by attempting to acquire share lock on the other transaction ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a transaction is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.

Advisory locks can be acquired on keys consisting of either a single `bigint` value or two integer values. A `bigint` key is displayed with its high-order half in the `classid` column, its low-order half in the `objid` column, and `objsubid` equal to 1. Integer keys are displayed with the first key in the `classid` column, the second key in the `objid` column, and `objsubid` equal to 2. The actual meaning of the keys

is up to the user. Advisory locks are local to each database, so the `database` column is meaningful for an advisory lock.

When the `pg_locks` view is accessed, the internal lock manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal lock manager operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

`pg_locks` provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its `relation` column can be joined against `pg_class.oid` to identify locked relations, this will only work correctly for relations in the current database (those for which the `database` column is either the current database's OID or zero).

The `pid` column can be joined to the `procpid` column of the `pg_stat_activity` view to get more information on the session holding or waiting to hold each lock. Also, if you are using prepared transactions, the `transaction` column can be joined to the `transaction` column of the `pg_prepared_xacts` view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.)

## 44.47. `pg_prepared_statements`

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See *PREPARE* for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the *DEALLOCATE* command).

**Table 44-47. `pg_prepared_statements` Columns**

Name	Type	Description
<code>name</code>	<code>text</code>	The identifier of the prepared statement
<code>statement</code>	<code>text</code>	The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <i>PREPARE</i> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself
<code>prepare_time</code>	<code>timestampz</code>	The time at which the prepared statement was created

Name	Type	Description
<code>parameter_types</code>	<code>regtype[]</code>	The expected parameter types for the prepared statement in the form of an array of <code>regtype</code> . The OID corresponding to an element of this array can be obtained by casting the <code>regtype</code> value to <code>oid</code>
<code>from_sql</code>	<code>boolean</code>	<code>true</code> if the prepared statement was created via the <code>PREPARE SQL</code> statement; <code>false</code> if the statement was prepared via the frontend/backend protocol

The `pg_prepared_statements` view is read only.

## 44.48. `pg_prepared_xacts`

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see *PREPARE TRANSACTION* for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

**Table 44-48. `pg_prepared_xacts` Columns**

Name	Type	References	Description
<code>transaction</code>	<code>xid</code>		Numeric transaction identifier of the prepared transaction
<code>gid</code>	<code>text</code>		Global transaction identifier that was assigned to the transaction
<code>prepared</code>	<code>timestamp with time zone</code>		Time at which the transaction was prepared for commit
<code>owner</code>	<code>name</code>	<code>pg_authid.rolname</code>	Name of the user that executed the transaction
<code>database</code>	<code>name</code>	<code>pg_database.datname</code>	Name of the database in which the transaction was executed

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a

consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there could be some impact on database performance if this view is frequently accessed.

## 44.49. pg\_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

**Table 44-49. `pg_roles` Columns**

Name	Type	References	Description
<code>rolname</code>	<code>name</code>		Role name
<code>rolsuper</code>	<code>bool</code>		Role has superuser privileges
<code>rolinherit</code>	<code>bool</code>		Role automatically inherits privileges of roles it is a member of
<code>rolcreaterole</code>	<code>bool</code>		Role can create more roles
<code>rolcreatedb</code>	<code>bool</code>		Role can create databases
<code>rolcatupdate</code>	<code>bool</code>		Role can update system catalogs directly. (Even a superuser cannot do this unless this column is true.)
<code>rolcanlogin</code>	<code>bool</code>		Role can log in. That is, this role can be given as the initial session authorization identifier
<code>rolconlimit</code>	<code>int4</code>		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit
<code>rolpassword</code>	<code>text</code>		Not the password (always reads as <code>*****</code> )

Name	Type	References	Description
<code>rolvaliduntil</code>	<code>timestampz</code>		Password expiry time (only used for password authentication); NULL if no expiration
<code>rolconfig</code>	<code>text[]</code>		Session defaults for run-time configuration variables
<code>oid</code>	<code>oid</code>	<code>pg_authid.oid</code>	ID of role

## 44.50. `pg_rules`

The view `pg_rules` provides access to useful information about query rewrite rules.

**Table 44-50. `pg_rules` Columns**

Name	Type	References	Description
<code>schemaname</code>	<code>name</code>	<code>pg_namespace.nspname</code>	Name of schema containing table
<code>tablename</code>	<code>name</code>	<code>pg_class.relname</code>	Name of table the rule is for
<code>rulename</code>	<code>name</code>	<code>pg_rewrite.rulename</code>	Name of rule
<code>definition</code>	<code>text</code>		Rule definition (a reconstructed creation command)

The `pg_rules` view excludes the `ON SELECT` rules of views; those can be seen in `pg_views`.

## 44.51. `pg_settings`

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.

**Table 44-51. `pg_settings` Columns**

Name	Type	Description
<code>name</code>	<code>text</code>	Run-time configuration parameter name
<code>setting</code>	<code>text</code>	Current value of the parameter
<code>unit</code>	<code>text</code>	Implicit unit of the parameter

Name	Type	Description
category	text	Logical group of the parameter
short_desc	text	A brief description of the parameter
extra_desc	text	Additional, more detailed, information about the parameter
context	text	Context required to set the parameter's value
vartype	text	Parameter type (bool, integer, real, or string)
source	text	Source of the current parameter value
min_val	text	Minimum allowed value of the parameter (NULL for non-numeric values)
max_val	text	Maximum allowed value of the parameter (NULL for non-numeric values)

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

## 44.52. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

**Table 44-52. `pg_shadow` Columns**

Name	Type	References	Description
username	name	<code>pg_authid.rolname</code>	User name
usesysid	oid	<code>pg_authid.oid</code>	ID of this user
usecreatedb	bool		User can create databases
usesuper	bool		User is a superuser

Name	Type	References	Description
usecatupd	bool		User can update system catalogs. (Even a superuser cannot do this unless this column is true.)
passwd	text		Password (possibly encrypted)
valuntil	abstime		Password expiry time (only used for password authentication)
useconfig	text[]		Session defaults for run-time configuration variables

## 44.53. pg\_stats

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

**Table 44-53. `pg_stats` Columns**

Name	Type	References	Description
schemaname	name	<code>pg_namespace.nspname</code>	Name of schema containing table
tablename	name	<code>pg_class.relname</code>	Name of table
attname	name	<code>pg_attribute.attname</code>	Name of the column described by this row
null_frac	real		Fraction of column entries that are null
avg_width	integer		Average width in bytes of column's entries

Name	Type	References	Description
n_distinct	real		If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows
most_common_vals	anyarray		A list of the most common values in the column. (NULL if no values seem to be more common than any others.)
most_common_freqs	real[]		A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (NULL when most_common_vals is.)

Name	Type	References	Description
histogram_bounds	anyarray		A list of values that divide the column's values into groups of approximately equal population. The values in <code>most_common_vals</code> , if present, are omitted from this histogram calculation. (This column is NULL if the column data type does not have a < operator or if the <code>most_common_vals</code> list accounts for the entire population.)
correlation	real		Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is NULL if the column data type does not have a < operator.)

The maximum number of entries in the `most_common_vals` and `histogram_bounds` arrays can be set on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the `default_statistics_target` run-time parameter.

## 44.54. pg\_tables

The view `pg_tables` provides access to useful information about each table in the database.

**Table 44-54. `pg_tables` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
schemaname	name	pg_namespace.nspname	Name of schema containing table
tablename	name	pg_class.relname	Name of table
tableowner	name	pg_authid.rolname	Name of table's owner
tablespace	name	pg_tablespace.spcname	Name of tablespace containing table (NULL if default for database)
hasindexes	boolean	pg_class.relhasindex	true if table has (or recently had) any indexes
hasrules	boolean	pg_class.relhasrules	true if table has rules
hastriggers	boolean	pg_class.reltriggers	true if table has triggers

## 44.55. pg\_timezone\_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the `timezone_abbreviations` run-time parameter is modified.

**Table 44-55. `pg_timezone_abbrevs` Columns**

Name	Type	Description
abbrev	text	Time zone abbreviation
utc_offset	interval	Offset from UTC (positive means east of Greenwich)
is_dst	boolean	True if this is a daylight-savings abbreviation

## 44.56. pg\_timezone\_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 44-56. `pg_timezone_names` Columns**

Name	Type	Description
name	text	Time zone name
abbrev	text	Time zone abbreviation
utc_offset	interval	Offset from UTC (positive means east of Greenwich)
is_dst	boolean	True if currently observing daylight savings

## 44.57. pg\_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 44-57. `pg_user` Columns**

Name	Type	Description
username	name	User name
usesysid	int4	User ID (arbitrary number used to reference this user)
usecreatedb	bool	User can create databases
usesuper	bool	User is a superuser
usecatupd	bool	User can update system catalogs. (Even a superuser cannot do this unless this column is true.)
passwd	text	Not the password (always reads as <code>*****</code> )
valuntil	abstime	Password expiry time (only used for password authentication)
useconfig	text[]	Session defaults for run-time configuration variables

## 44.58. pg\_views

The view `pg_views` provides access to useful information about each view in the database.

**Table 44-58. `pg_views` Columns**

Name	Type	References	Description
schemaname	name	<code>pg_namespace.nspname</code>	Name of schema containing view
viewname	name	<code>pg_class.relname</code>	Name of view

Name	Type	References	Description
viewowner	name	pg_authid.rolname	Name of view's owner
definition	text		View definition (a reconstructed SELECT query)

# Chapter 45. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use, and then the server follows that protocol if it is able.

Higher level features built on this protocol (for example, how libpq passes certain environment variables when the connection is established) are covered elsewhere.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

## 45.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as `NOTIFY`) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as `COPY`.

### 45.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

### 45.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: *prepared statements* and *portals*. A prepared statement represents the result of parsing, semantic analysis, and (optionally) planning of a textual query string. A prepared statement is not necessarily ready to execute, because it might lack specific values for *parameters*. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For `SELECT` statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don't handle non-`SELECT` statements.)

The overall execution cycle consists of a *parse* step, which creates a prepared statement from a textual query string; a *bind* step, which creates a portal given a prepared statement and values for any needed parameters; and an *execute* step that runs a portal's query. In the case of a query that returns rows (`SELECT`, `SHOW`, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

### 45.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different *formats*. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a *format code*. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

## 45.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 45.4.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, `COPY`, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

### 45.2.1. Start-Up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as `pg_hba.conf`) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI and SSPI, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (`ErrorResponse`), or sending `AuthenticationOk`.

The possible messages from the server in this phase are:

#### `ErrorResponse`

The connection attempt has been rejected. The server then immediately closes the connection.

#### `AuthenticationOk`

The authentication exchange is successfully completed.

#### `AuthenticationKerberosV5`

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

**AuthenticationCleartextPassword**

The frontend must now send a `PasswordMessage` containing the password in clear-text form. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

**AuthenticationCryptPassword**

The frontend must now send a `PasswordMessage` containing the password encrypted via `crypt(3)`, using the 2-character salt specified in the `AuthenticationCryptPassword` message. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

**AuthenticationMD5Password**

The frontend must now send a `PasswordMessage` containing the password encrypted via MD5, using the 4-character salt specified in the `AuthenticationMD5Password` message. If this is the correct password, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

**AuthenticationSCMCredential**

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it's only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an `AuthenticationOk`, otherwise it responds with an `ErrorResponse`.

**AuthenticationGSS**

The frontend must now initiate a GSSAPI negotiation. The frontend will send a `PasswordMessage` with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

**AuthenticationSSPI**

The frontend must now initiate a SSPI negotiation. The frontend will send a `PasswordMessage` with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with `AuthenticationGSSContinue`.

**AuthenticationGSSContinue**

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (`AuthenticationGSS`, `AuthenticationSSPI` or a previous `AuthenticationGSSContinue`). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another `PasswordMessage`. If GSSAPI or SSPI authentication is completed by this message, the server will next send `AuthenticationOk` to indicate successful authentication or `ErrorResponse` to indicate failure.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received `AuthenticationOk`, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (`ErrorResponse`), but in the normal case the backend will send some `ParameterStatus` messages, `BackendKeyData`, and finally `ReadyForQuery`.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

#### BackendKeyData

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

#### ParameterStatus

This message informs the frontend about the current (initial) setting of backend parameters, such as client\_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 45.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

#### ReadyForQuery

Start-up is completed. The frontend can now issue commands.

#### ErrorResponse

Start-up failed. The connection is closed after sending this message.

#### NoticeResponse

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

## 45.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

#### CommandComplete

An SQL command completed normally.

**CopyInResponse**

The backend is ready to copy data from the frontend to a table; see Section 45.2.5.

**CopyOutResponse**

The backend is ready to copy data from a table to the frontend; see Section 45.2.5.

**RowDescription**

Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

**DataRow**

One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

**EmptyQueryResponse**

An empty query string was recognized.

**ErrorResponse**

An error has occurred.

**ReadyForQuery**

Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (`CommandComplete` marks the end of processing one SQL command, not the whole string.) `ReadyForQuery` will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**

A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of `RowDescription`, zero or more `DataRow` messages, and then `CommandComplete`. `COPY` to or from the frontend invokes special protocol as described in Section 45.2.5. All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. `ReadyForQuery` is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by `ReadyForQuery`.

In the event of an error, `ErrorResponse` is issued followed by `ReadyForQuery`. All further processing of the query string is aborted by `ErrorResponse` (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the `RowDescription` message tell which format is being used.

A frontend must be prepared to accept `ErrorResponse` and `NoticeResponse` messages whenever it is expecting any other type of message. See also Section 45.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 45.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a `Parse` message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either `ParseComplete` or `ErrorResponse`. Parameter data types can be specified by `OID`; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

**Note:** A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type `OIDs` shorter than the number of parameter symbols (`$n`) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the `OID` of the `void` pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually `OUT` parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1, $2, $3, $4)` could match a function with two `IN` and two `OUT` arguments, if `$3` and `$4` are specified as having type `void`.

**Note:** The query string contained in a `Parse` message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next `Parse` statement specifying the unnamed statement as destination is issued. (Note that a simple `Query` message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by a `Parse` message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a `Bind` message. The `Bind` message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the `Parse` message, pass `NULL` values for them in the `Bind` message.) `Bind` also specifies the format to use for any data returned

by the query; the format can be specified overall, or per-column. The response is either `BindComplete` or `ErrorResponse`.

**Note:** The choice between text and binary output is determined by the format codes given in `Bind`, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning for named prepared-statement objects occurs when the `Parse` message is processed. If a query will be repeatedly executed with different parameters, it might be beneficial to send a single `Parse` message containing a parameterized query, followed by multiple `Bind` and `Execute` messages. This will avoid replanning the query on each execution.

The unnamed prepared statement is likewise planned during `Parse` processing if the `Parse` message defines no parameters. But if there are parameters, query planning occurs during `Bind` processing instead. This allows the planner to make use of the actual values of the parameters provided in the `Bind` message when planning the query.

**Note:** Query plans generated from a parameterized query might be less efficient than query plans generated from an equivalent query with actual parameter values substituted. The query planner cannot make decisions based on actual parameter values (for example, index selectivity) when planning a parameterized query assigned to a named prepared-statement object. This possible penalty is avoided when using the unnamed statement, since it is not planned until actual parameter values are available. The cost is that planning must occur afresh for each `Bind`, even if the query stays the same.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next `Bind` statement specifying the unnamed portal as destination is issued. (Note that a simple `Query` message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by a `Bind` message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an `Execute` message. The `Execute` message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to `Execute` are the same as those described above for queries issued via simple query protocol, except that `Execute` doesn’t cause `ReadyForQuery` or `RowDescription` to be issued.

If `Execute` terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a `PortalSuspended` message; the appearance of this message tells the frontend that another `Execute` should be issued against the same portal to complete the operation. The `CommandComplete` message indicating completion of the source SQL command is not sent until the portal’s execution is completed. Therefore, an `Execute` phase is always terminated by the appearance of exactly one of these messages: `CommandComplete`, `EmptyQueryResponse` (if the portal was created from an empty query string), `ErrorResponse`, or `PortalSuspended`.

At completion of each series of extended-query messages, the frontend should issue a `Sync` message. This parameterless message causes the backend to close the current transaction if it’s not inside a

BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected *while* processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

**Note:** Sync does not cause a transaction block opened with BEGIN to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

**Tip:** In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note:** The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.

### 45.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database's `pg_proc` system catalog. The client must have `execute` permission for the function.

**Note:** The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a `FunctionCall` message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a `ReadyForQuery` response message. `ReadyForQuery` informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

#### ErrorResponse

An error has occurred.

#### FunctionCallResponse

The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)

#### ReadyForQuery

Processing of the function call is complete. `ReadyForQuery` will always be sent, whether processing terminates successfully or with an error.

#### NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

### 45.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a `CopyInResponse` message to the frontend. The frontend should then send zero or more `CopyData` messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a `CopyDone` message (allowing successful termination) or a `CopyFail` message (which will cause the `COPY SQL` statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either `CommandComplete` (if successful) or `ErrorResponse` (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a `CopyFail` message), the backend will issue an `ErrorResponse` message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a `Sync` message is received, then it will issue `ReadyForQuery` and return to normal processing. If the `COPY` command was issued in a simple `Query` message, the rest of that message is discarded and `ReadyForQuery` is issued. In either case, any subsequent `CopyData`, `CopyDone`, or `CopyFail` messages issued by the frontend will simply be dropped.

The backend will ignore `Flush` and `Sync` messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for `Flush` and `Sync` is for the convenience of client libraries that always send `Flush` or `Sync` after an `Execute` message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a `CopyOutResponse` message to the frontend, followed by zero or more `CopyData` messages (always one per row), followed by `CopyDone`. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends `CommandComplete`. The frontend cannot abort the transfer (except by closing the connection or issuing a `Cancel` request), but it can discard unwanted `CopyData` and `CopyDone` messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an `ErrorResponse` message and revert to normal processing. The frontend should treat receipt of `ErrorResponse` as terminating the copy-out mode.

It is possible for `NoticeResponse` and `ParameterStatus` messages to be interspersed between `CopyData` messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 45.2.6). Otherwise, any message type other than `CopyData` or `CopyDone` may be treated as terminating copy-out mode.

The `CopyInResponse` and `CopyOutResponse` messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given `COPY` operation will use the same format, but the message design does not assume this.)

## 45.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend's command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for `NoticeResponse` messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a `NoticeResponse` indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display `NoticeResponse` messages, even when the connection is nominally idle.

`ParameterStatus` messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a `SET SQL` command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the `SIGHUP` signal to the server. Also, if a `SET` command is rolled back, an appropriate `ParameterStatus` message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which `ParameterStatus` will be generated: they are `server_version`, `server_encoding`, `client_encoding`, `is_superuser`, `session_authorization`, `DateStyle`, `TimeZone`, `integer_datetimes`, and `standard_conforming_strings`. (`server_encoding`, `TimeZone`, and `integer_datetimes` were not reported by releases before 8.0; `standard_conforming_strings` was not reported by releases before 8.1.) Note that `server_version`, `server_encoding` and `integer_datetimes` are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore `ParameterStatus` for parameters that it does not understand or care about.

If a frontend issues a `LISTEN` command, then the backend will send a `NotificationResponse` message (not to be confused with `NoticeResponse`!) whenever a `NOTIFY` command is executed for the same notification name.

**Note:** At present, `NotificationResponse` can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before `ReadyForQuery`. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept `NotificationResponse` at any point in the protocol.

## 45.2.7. Cancelling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don't want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a `CancelRequest` message, rather than the `StartupMessage` message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A `CancelRequest` message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building

multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 45.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a `Terminate` message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn't want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

### 45.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 17.8.

To initiate an SSL-encrypted connection, the frontend initially sends an `SSLRequest` message rather than a `StartupMessage`. The server then responds with a single byte containing `S` or `N`, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after `S`, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual `StartupMessage`. In this case the `StartupMessage` and all subsequent data will be SSL-encrypted. To continue after `N`, send the usual `StartupMessage` and proceed without encryption.

The frontend should also be prepared to handle an `ErrorMessage` response to `SSLRequest` from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial `SSLRequest` can also be used in a connection that is being opened to send a `CancelRequest` message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

## 45.3. Message Data Types

This section describes the base data types used in messages.

`Int $n$ ( $i$ )`

An  $n$ -bit integer in network byte order (most significant byte first). If  $i$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `Int16`, `Int32(42)`.

`Int $n$ [ $k$ ]`

An array of  $k$   $n$ -bit integers, each in network byte order. The array length  $k$  is always determined by an earlier field in the message. Eg. `Int16[M]`.

`String( $s$ )`

A null-terminated string (C-style string). There is no specific length limitation on strings. If  $s$  is specified it is the exact value that will appear, otherwise the value is variable. Eg. `String`, `String("user")`.

**Note:** *There is no predefined limit* on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don't fit into your fixed-size buffer.

`Byte $n$ ( $c$ )`

Exactly  $n$  bytes. If the field width  $n$  is not a constant, it is always determinable from an earlier field in the message. If  $c$  is specified it is the exact value. Eg. `Byte2`, `Byte1('\n')`.

## 45.4. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The `CopyData` message is an exception, because it forms part of a data stream; the contents of any individual `CopyData` message cannot be interpretable on their own.)

`AuthenticationOk` (B)

`Byte1('R')`

Identifies the message as an authentication request.

`Int32(8)`

Length of message contents in bytes, including self.

Int32(0)

Specifies that the authentication was successful.

#### AuthenticationKerberosV5 (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(2)

Specifies that Kerberos V5 authentication is required.

#### AuthenticationCleartextPassword (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(3)

Specifies that a clear-text password is required.

#### AuthenticationCryptPassword (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(10)

Length of message contents in bytes, including self.

Int32(4)

Specifies that a crypt()-encrypted password is required.

Byte2

The salt to use when encrypting the password.

#### AuthenticationMD5Password (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(12)

Length of message contents in bytes, including self.

Int32(5)

Specifies that an MD5-encrypted password is required.

Byte4

The salt to use when encrypting the password.

#### AuthenticationSCMCredential (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(6)

Specifies that an SCM credentials message is required.

#### AuthenticationGSS (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(7)

Specifies that GSSAPI authentication is required.

#### AuthenticationSSPI (B)

Byte1('R')

Identifies the message as an authentication request.

Int32(8)

Length of message contents in bytes, including self.

Int32(9)

Specifies that SSPI authentication is required.

## AuthenticationGSSContinue (B)

Byte1('R')

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte<sub>n</sub>

GSSAPI or SSPI authentication data.

## BackendKeyData (B)

Byte1('K')

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

## Bind (F)

Byte1('B')

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).

Int16

The number of parameter format codes that follow (denoted  $C$  below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16[ $C$ ]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte $n$

The value of the parameter, in the format indicated by the associated format code.  $n$  is the above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted  $R$  below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16[ $R$ ]

The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1('2')

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least 16 significant bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.

For an `INSERT` command, the tag is `INSERT oid rows`, where `rows` is the number of rows inserted. `oid` is the object ID of the inserted row if `rows` is 1 and the target table has OIDs; otherwise `oid` is 0.

For a `DELETE` command, the tag is `DELETE rows` where `rows` is the number of rows deleted.

For an `UPDATE` command, the tag is `UPDATE rows` where `rows` is the number of rows updated.

For a `MOVE` command, the tag is `MOVE rows` where `rows` is the number of rows the cursor's position has been changed by.

For a `FETCH` command, the tag is `FETCH rows` where `rows` is the number of rows that have been retrieved from the cursor.

For a `COPY` command, the tag is `COPY rows` where `rows` is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

### CopyData (F & B)

Byte1('d')

Identifies the message as `COPY` data.

Int32

Length of message contents in bytes, including self.

Byte<sub>*n*</sub>

Data that forms part of a `COPY` data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

### CopyDone (F & B)

Byte1('c')

Identifies the message as a `COPY`-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

### CopyFail (F)

Byte1('f')

Identifies the message as a `COPY`-failure indicator.

Int32

Length of message contents in bytes, including self.

String

An error message to report as the cause of failure.

### CopyInResponse (B)

Byte1('G')

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See *COPY* for more information.

Int16

The number of columns in the data to be copied (denoted *N* below).

Int16[*N*]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

### CopyOutResponse (B)

Byte1('H')

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See *COPY* for more information.

Int16

The number of columns in the data to be copied (denoted *N* below).

Int16[*N*]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

## DataRow (B)

Byte1('D')

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte<sub>*n*</sub>The value of the column, in the format indicated by the associated format code. *n* is the above length.

## Describe (F)

Byte1('D')

Identifies the message as a Describe command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to describe a prepared statement; or 'P' to describe a portal.

String

The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

## EmptyQueryResponse (B)

Byte1('I')

Identifies the message as a response to an empty query string. (This substitutes for Command-Complete.)

Int32(4)

Length of message contents in bytes, including self.

## ErrorResponse (B)

Byte1('E')

Identifies the message as an error.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 45.5. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

## Execute (F)

Byte1('E')

Identifies the message as an Execute command.

Int32

Length of message contents in bytes, including self.

String

The name of the portal to execute (an empty string selects the unnamed portal).

Int32

Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

## Flush (F)

Byte1('H')

Identifies the message as a Flush command.

Int32(4)

Length of message contents in bytes, including self.

## FunctionCall (F)

Byte1('F')

Identifies the message as a function call.

Int32

Length of message contents in bytes, including self.

Int32

Specifies the object ID of the function to call.

Int16

The number of argument format codes that follow (denoted *C* below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[*C*]

The argument format codes. Each must presently be zero (text) or one (binary).

Int16

Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32

The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte<sub>*n*</sub>

The value of the argument, in the format indicated by the associated format code. *n* is the above length.

After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

## FunctionCallResponse (B)

Byte1('V')

Identifies the message as a function call result.

Int32

Length of message contents in bytes, including self.

Int32

The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte $n$

The value of the function result, in the format indicated by the associated format code.  $n$  is the above length.

NoData (B)

Byte1('n')

Identifies the message as a no-data indicator.

Int32(4)

Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')

Identifies the message as a notice.

Int32

Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1

A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 45.5. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String

The field value.

NotificationResponse (B)

Byte1('A')

Identifies the message as a notification response.

Int32

Length of message contents in bytes, including self.

Int32

The process ID of the notifying backend process.

String

The name of the condition that the notify has been raised on.

String

Additional information passed from the notifying process. (Currently, this feature is unimplemented so the field is always an empty string.)

ParameterDescription (B)

Byte1('t')

Identifies the message as a parameter description.

Int32

Length of message contents in bytes, including self.

Int16

The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')

Identifies the message as a run-time parameter status report.

Int32

Length of message contents in bytes, including self.

String

The name of the run-time parameter being reported.

String

The current value of the parameter.

Parse (F)

Byte1('P')

Identifies the message as a Parse command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination prepared statement (an empty string selects the unnamed prepared statement).

String

The query string to be parsed.

Int16

The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI and SSPI response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message's row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.

String

The query string itself.

ReadyForQuery (B)

Byte1('Z')

Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)

Length of message contents in bytes, including self.

Byte1

Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')

Identifies the message as a row description.

Int32

Length of message contents in bytes, including self.

Int16

Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String

The field name.

Int32

If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16

If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32

The object ID of the field's data type.

Int16

The data type size (see `pg_type.typelen`). Note that negative values denote variable-width types.

Int32

The type modifier (see `pg_attribute.atttypmod`). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a `RowDescription` returned from the statement variant of `Describe`, the format code is not yet known and will always be zero.

## SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least 16 significant bits. (To avoid confusion, this code must not be the same as any protocol version number.)

## StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. `user` is required, others are optional. Each parameter is specified as:

**String**

The parameter name. Currently recognized names are:

`user`

The database user name to connect as. Required; there is no default.

`database`

The database to connect to. Defaults to the user name.

`options`

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.)

In addition to the above, any run-time parameter that can be set at backend start time might be listed. Such settings will be applied during backend start (after parsing the command-line options if any). The values will act as session defaults.

**String**

The parameter value.

**Sync (F)**

`Byte1('S')`

Identifies the message as a Sync command.

`Int32(4)`

Length of message contents in bytes, including self.

**Terminate (F)**

`Byte1('X')`

Identifies the message as a termination.

`Int32(4)`

Length of message contents in bytes, including self.

## 45.5. Error and Notice Message Fields

This section describes the fields that can appear in `ErrorResponse` and `NoticeResponse` messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

S

Severity: the field contents are `ERROR`, `FATAL`, or `PANIC` (in an error message), or `WARNING`, `NOTICE`, `DEBUG`, `INFO`, or `LOG` (in a notice message), or a localized translation of one of these. Always present.

C

Code: the `SQLSTATE` code for the error (see Appendix A). Not localizable. Always present.

M

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

D

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P

Internal position: this is defined the same as the `P` field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The `q` field will always appear when this field appears.

q

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

F

File: the file name of the source-code location where the error was reported.

L

Line: the line number of the source-code location where the error was reported.

R

Routine: the name of the source-code routine reporting the error.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

## 45.6. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn't a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that `PasswordMessage` now has a type byte.

`ErrorResponse` and `NoticeResponse` ('E' and 'N') messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The `ReadyForQuery` ('Z') message includes a transaction status indicator.

The distinction between `BinaryRow` and `DataRow` message types is gone; the single `DataRow` message type serves for returning data in all formats. Note that the layout of `DataRow` has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server's internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types `Parse`, `Bind`, `Execute`, `Describe`, `Close`, `Flush`, and `Sync`, and the backend message types `ParseComplete`, `BindComplete`, `PortalSuspended`, `ParameterDescription`, `NoData`, and `CloseComplete`. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

`COPY` data is now encapsulated into `CopyData` and `CopyDone` messages. There is a well-defined way to recover from errors during `COPY`. The special “\.” last line is not needed anymore, and is not sent during `COPY OUT`. (It is still recognized as a terminator during `COPY IN`, but its use is deprecated and will eventually be removed.) Binary `COPY` is supported. The `CopyInResponse` and `CopyOutResponse` messages include fields indicating the number of columns and the format of each column.

The layout of `FunctionCall` and `FunctionCallResponse` messages has changed. `FunctionCall` can now support passing `NULL` arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider `FunctionCall` a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends `ParameterStatus` ('S') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a `ParameterStatus` message is sent whenever the active value changes for any of these parameters.

The `RowDescription` ('T') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The `CursorResponse` ('P') message is no longer generated by the backend.

The `NotificationResponse` ('A') message has an additional string field, which is presently empty but might someday carry additional data passed from the `NOTIFY` event sender.

The `EmptyQueryResponse` ('I') message used to include an empty string parameter; this has been removed.

# Chapter 46. PostgreSQL Coding Conventions

## 46.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e. tabs are not expanded to spaces). Each logical indentation level is one additional tab stop. Layout rules (brace positioning, etc) follow BSD conventions.

While submitted patches do not absolutely have to follow these formatting rules, it's a good idea to do so. Your code will get run through `pgindent`, so there's no point in making it look nice under some other set of formatting conventions.

The `src/tools` directory contains sample settings files that can be used with the `emacs`, `xemacs` or `vim` editors to help ensure that they format code according to these conventions.

The text browsing tools `more` and `less` can be invoked as:

```
more -x4
less -x4
```

to make them show tabs appropriately.

## 46.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec's `SQLSTATE` conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```
ereport (ERROR,
        (errcode (ERRCODE_DIVISION_BY_ZERO),
         errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the `SQLSTATE` error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```
ereport (ERROR,
        (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
         errmsg("function %s is not unique",
                func_signature_string(funcname, nargs,
                                     actual_arg_types)),
         errhint("Unable to choose a best candidate function. "
                 "You might need to add explicit typecasts.")));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.
- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`.<sup>1</sup> `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.
- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.
- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.
- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.
- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.
- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

---

1. That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`’s parameter list; accordingly, do not do so.

- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.
- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.
- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

There is an older function `elog` that is still heavily used. An `elog` call:

```
elog(level, "format string", ...);
```

is exactly equivalent to:

```
ereport(level, (errmsg_internal("format string", ...)));
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not included in the internationalization message dictionary. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 46.3.

## 46.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

### 46.3.1. What goes where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

```
IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m
(plus a long addendum that is basically a hint)
```

write:

```

Primary:    could not create shared memory segment: %m
Detail:     Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint:       the addendum

```

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users don't know the details anyway.

### 46.3.2. Formatting

Don't put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (`\n`) can be used to indicate suggested paragraph breaks. Don't end a message with a newline. Don't use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.

### 46.3.3. Quotation marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-internal technical issue that many users aren't even familiar with, it won't scale to other kinds of quoted terms, it doesn't translate to other languages, and it's pretty pointless, too.

### 46.3.4. Use of quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don't clutter messages with unnecessary or duplicate quote marks.

### 46.3.5. Grammar and punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they're long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there's only one sentence.

### 46.3.6. Upper case vs. lower case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It's easier to make everything look more consistent this way, since some messages are complete sentences and some not.

### 46.3.7. Avoid passive voice

Use the active voice. Use complete sentences when there is an acting subject ("A could not do B"). Use telegram style without subject if the subject would be the program itself; do not use "I" for the program.

Rationale: The program is not human. Don't pretend otherwise.

### 46.3.8. Present vs past tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

```
could not open file "%s": %m
```

and:

```
cannot open file "%s"
```

The first one means that the attempt to open the file failed. The message should give a reason, such as "disk full" or "file doesn't exist". The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it's conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

### 46.3.9. Type of the object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

### 46.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

### 46.3.11. Assembling error messages

When a message includes text that is generated elsewhere, embed it in this style:

```
could not open file %s: %m
```

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it's unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

### 46.3.12. Reasons for errors

Messages should always state the reason why an error occurred. For example:

```
BAD:      could not open file %s
BETTER:  could not open file %s (I/O failure)
```

If no reason is known you better fix the code.

### 46.3.13. Function names

Don't include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it's not helpful information. If the error text doesn't make as much sense without the function name, reword it.

```
BAD:      pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"
```

Avoid mentioning called function names, either; instead say what the code was trying to do:

```
BAD:      open() failed: %m
BETTER: could not open file %s: %m
```

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don't know what all those functions do.

### 46.3.14. Tricky words to avoid

**Unable.** “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

**Bad.** Error messages like “bad result” are really hard to interpret intelligently. It's better to write why the result is “bad”, e.g., “invalid format”.

**Illegal.** “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it's invalid.

**Unknown.** Try to avoid “unknown”. Consider “error: unknown response”. If you don't know what the response is, how do you know it's erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

```
BAD:      unknown node type
BETTER: unrecognized node type: 42
```

**Find vs. Exists.** If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn't “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn't “exist”. Using “find” in this case sounds weak and confuses the issue.

**May vs. Can vs. Might.** “May” suggests permission (e.g. “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g. “I can lift that log.”), and “might” suggests possibility (e.g. “It might rain today.”). Using the proper word clarifies meaning and assists translation.

**Contractions.** Avoid contractions, like “can't”; use “cannot” instead.

### 46.3.15. Proper spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth
- xact

Rationale: This will improve consistency.

### 46.3.16. Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 47.2.2 to avoid making life difficult for translators.

# Chapter 47. Native Language Support

## 47.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

### 47.1.1. Requirements

We won't judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the `libintl` library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won't need `xgettext`. (From CVS, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

### 47.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in *message catalogs*, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either `.po` or `.mo`. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for `psql`) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```
# comment

msgid "original string"
msgstr "translated string"
```

```
msgid "more original"
msgstr "another translated"
"string can be broken up like this"

...
```

The `msgid`'s are extracted from the program source. (They need not be, but this is the most common way.) The `msgstr` lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The `#` character introduces a comment. If whitespace immediately follows the `#` character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the `#`. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

```
#. automatic comment
#: filename.c:1023
#, flags, flags
```

The `#.` style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The `#:` comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but he can if there is doubt about the correct translation. The `#,` comments contain flags that describe the message in some way. There are currently two flags: `fuzzy` is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is `c-format`, which indicates that the message is a `printf`-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the `c-format` flag.

### 47.1.3. Creating and maintaining message catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file `nls.mk`, then this program has been prepared for translation.

If there are already some `.po` files, then someone has already done some translation work. The files are named `language.po`, where `language` is the ISO 639-1 two-letter language code (in lower case)<sup>1</sup>, e.g., `fr.po` for French. If there is really a need for more than one translation effort per language then the files can also be named `language_region.po` where `region` is the ISO 3166-1 two-letter country code (in upper case)<sup>2</sup>, e.g., `pt_BR.po` for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
gmake init-po
```

- 
1. <http://lcweb.loc.gov/standards/iso639-2/englagn.html>
  2. [http://www.din.de/gremien/nas/nabd/iso3166ma/codlstp1/en\\_listp1.html](http://www.din.de/gremien/nas/nabd/iso3166ma/codlstp1/en_listp1.html)

This will create a file `progrname.pot`. (.pot to distinguish it from PO files that are “in production”. The `T` stands for “template”.) Copy this file to `language.po` and edit it. To make it known that the new language is available, also edit the file `nls.mk` and add the language (or language and country) code to the line that looks like:

```
AVAIL_LANGUAGES := de fr
```

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
gmake update-po
```

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. For the case where something went really wrong, the old PO file is saved with a `.po.old` extension.

### 47.1.4. Editing the PO files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

```
msgstr "Die Datei %2$s hat %1$u Zeichen."
```

Then the first placeholder will actually use the second argument from the list. The `digits$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.
- Maintain the style and tone of the original string. Specifically, messages that are not sentences (`cannot open file %s`) should probably not start with a capital letter (if your language distinguishes letter

case) or end with a period (if your language uses punctuation marks). It might help to read Section 46.3.

- If you don't know what a message means, or if it is ambiguous, ask on the developers' mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it's best to improve the message.

## 47.2. For the Programmer

### 47.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

#### Adding NLS support to a program

1. Insert this code into the start-up sequence of the program:

```
#ifdef ENABLE_NLS
#include <locale.h>
#endif

...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("progrname", LOCALEDIR);
textdomain("progrname");
#endif
```

(The *progrname* can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```
fprintf(stderr, "panic level %d\n", lvl);
would be changed to:

fprintf(stderr, gettext("panic level %d\n"), lvl);
(gettext is defined as a no-op if no NLS is configured.)
```

This tends to add a lot of clutter. One common shortcut is to use:

```
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

CATALOG\_NAME

The program name, as provided in the `textdomain()` call.

AVAIL\_LANGUAGES

List of provided translations — initially empty.

GETTEXT\_FILES

List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a + and the second word be a file that contains one file name per line.

GETTEXT\_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only `gettext()` calls are known. If you used `_` or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form `func:2` (for the second argument).

The build system will automatically take care of building and installing the message catalogs.

## 47.2.2. Message-writing guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:

```
printf("Files were %s.\n", flag ? "copied" : "removed");
```

The word order within the sentence might be different in other languages. Also, even if you remember to call `gettext()` on each fragment, the fragments might not translate well separately. It's better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

- For similar reasons, this won't work:

```
printf("copied %d file%s", n, n!=1 ? "s" : "");
```

because it assumes how the plural is formed. If you figured you could solve it like this:

```
if (n==1)
    printf("copied 1 file");
else
    printf("copied %d files", n);
```

then be disappointed. Some languages have more than two forms, with some peculiar rules. We might have a solution for this in the future, but for now the matter is best avoided altogether. You could write:

```
printf("number of copied files: %d", n);
```

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

```
/* translator: This message is not what it seems to be. */
```

These comments are copied to the message catalog files so that the translators can see them.

# Chapter 48. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface), go through a *call handler* function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type `language_handler`. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a `Datum` result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the system table `pg_proc` and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-`NULL` then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData`’s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum          retval;

    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger procedure
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;

        retval = ...
    }
    else
    {
        /*
         * Called as a function
         */

        retval = ...
    }

    return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 34.9.6), the following commands then register the sample procedural language:

```
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
AS 'filename'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

The procedural languages included in the standard distribution are good references when trying to write your own call handler. Look into the `src/pl` subdirectory of the source tree.

# Chapter 49. Genetic Query Optimizer

**Author:** Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

## 49.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM's System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

## 49.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through nondeterministic, randomized search. The set of possible solutions for the optimization problem is considered as a *population* of *individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors.

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

### Figure 49-1. Structured Diagram of a Genetic Algorithm

$P(t)$	generation of ancestors at a time $t$
$P''(t)$	generation of descendants at a time $t$

[illegible]

### 49.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

$$\begin{array}{c} \wedge \\ \wedge \quad 2 \\ \wedge \quad 3 \\ 4 \quad 1 \end{array}$$

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- Usage of a *steady state* GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 49.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. Hence different plans may be selected from one run to the next, resulting in varying run time and varying output row order.

### 49.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file `src/backend/optimizer/geqo/geqo_main.c`, routines `gimme_pool_size` and `gimme_number_generations`, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates

use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

## 49.4. Further Reading

# Chapter 50. Index Access Method Interface Definition

This chapter defines the interface between the core PostgreSQL system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 53.3, and they all use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index's parent table. A TID consists of a block number and an item number within that block (see Section 53.3). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

## 50.1. Catalog Entries for Indexes

Each index access method is described by a row in the `pg_am` system catalog (see Section 44.3). The principal contents of a `pg_am` row are references to `pg_proc` entries that identify the index access functions supplied by the access method. The APIs for these functions are defined later in this chapter. In addition, the `pg_am` row specifies a few fixed properties of the access method, such as whether it can support multi-column indexes. There is not currently any special support for creating or deleting `pg_am` entries; anyone able to write a new access method is expected to be competent to insert an appropriate row for themselves.

To be useful, an index access method must also have one or more *operator families* and *operator classes* defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 34.14, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in

`pg_index`. Both of these catalog entries can be accessed as part of the `Relation` data structure that is passed to all operations on the index.

Some of the flag columns of `pg_am` have nonobvious implications. The requirements of `amcanunique` are discussed in Section 50.5. The `amcanmulticol` flag asserts that the access method supports multicolumn indexes, while `amoptionalkey` asserts that it allows scans where no indexable restriction clause is given for the first index column. When `amcanmulticol` is false, `amoptionalkey` essentially says whether the access method allows full-index scans without any restriction clause. Access methods that support multiple index columns *must* support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting `amoptionalkey` false. `amindexnulls` asserts that index entries are created for NULL key values. Since most indexable operators are strict and hence cannot return TRUE for NULL inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have `amoptionalkey` true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns *must* support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with `WHERE a = 4`. The system will assume the index can be used to scan for rows with `a = 4`, which is wrong if the index omits rows where `b` is null. It is, however, OK to omit rows where the first indexed column is null. Thus, `amindexnulls` should be set true only if the index access method indexes all rows, including arbitrary combinations of null values. An index access method that sets `amindexnulls` may also set `amsearchnulls`, indicating that it supports `IS NULL` clauses as search conditions.

## 50.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide are:

```
IndexBuildResult *
ambuild (Relation heapRelation,
         Relation indexRelation,
         IndexInfo *indexInfo);
```

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the `ambuild` function will call `IndexBuildHeapScan()` to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc'd struct containing statistics about the new index.

```
bool
aminsert (Relation indexRelation,
          Datum *values,
          bool *isnull,
          ItemPointer heap_tid,
          Relation heapRelation,
          bool check_uniqueness);
```

Insert a new tuple into an existing index. The `values` and `isnull` arrays give the key values to be indexed, and `heap_tid` is the TID to be indexed. If the access method supports unique indexes (its `pg_am.amcanunique` flag is true) then `check_uniqueness` might be true, in which case the access method must verify that there is no conflicting row; this is the only situation in which the access method normally needs the `heapRelation` parameter. See Section 50.5 for details. The result is TRUE if an index entry was inserted, FALSE if not. (A FALSE result does not denote an error condition, but is used for cases such as an index AM refusing to index a NULL.)

```
IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
              IndexBulkDeleteResult *stats,
              IndexBulkDeleteCallback callback,
              void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in `callback` function must be called, in the style `callback(TID, callback_state)` returns `bool`, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to `amvacuumcleanup`.

Because of limited `maintenance_work_mem`, `ambulkdelete` might need to be called more than once when many tuples are to be deleted. The `stats` argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, `ambulkdelete` will modify and return the same struct if the passed `stats` is not null.

```
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                 IndexBulkDeleteResult *stats);
```

Clean up after a VACUUM operation (zero or more `ambulkdelete` calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. `stats` is whatever the last `ambulkdelete` call returned, or NULL if `ambulkdelete` was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics it contains will be used to update `pg_class`, and will be reported by VACUUM if VERBOSE is given. It is OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

```
void
amcostestimate (PlannerInfo *root,
                IndexOptInfo *index,
                List *indexQuals,
                RelOptInfo *outer_rel,
                Cost *indexStartupCost,
                Cost *indexTotalCost,
                Selectivity *indexSelectivity,
                double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in Section 50.6, below.

```
bytea *
amoptions (ArrayType *reloptions,
          bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. `reloptions` is a text array containing entries of the form *name=value*. The function should construct a `bytea` value, which will be copied into the `rd_options` field of the index's relcache entry. The data contents of the `bytea` value are open for the access method to define, but the standard access methods currently all use struct `StdRdOptions`. When `validate` is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when `validate` is false, invalid entries should be silently ignored. (`validate` is false when loading options already stored in `pg_catalog`; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a *qualifier* or *scan key*. The semantics of index scanning are described more fully in Section 50.3, below. The scan-related functions that an index access method must provide are:

```
IndexScanDesc
ambeginscan (Relation indexRelation,
            int nkeys,
            ScanKey key);
```

Begin a new scan. The `key` array (of length `nkeys`) describes the scan key(s) for the index scan. The result must be a palloc'd struct. For implementation reasons the index access method *must* create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` itself does little beyond making that call; the interesting parts of index-scan startup are in `amrescan`.

```
boolean
amgettupple (IndexScanDesc scan,
            ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the `scan` structure. Note that "success" means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller's snapshot test.

```
boolean
amgetmulti (IndexScanDesc scan,
            ItemPointer tids,
            int32 max_tids,
            int32 *returned_tids);
```

Fetch multiple tuples in the given scan. Returns TRUE if the scan should continue, FALSE if no matching tuples remain. `tids` points to a caller-supplied array of `max_tids` `ItemPointerData` records, which the call fills with TIDs of matching tuples. `*returned_tids` is set to the number of TIDs actually returned. This can be less than `max_tids`, or even zero, even when the return value is TRUE. (This provision allows the access method to choose the most efficient stopping points in its scan, for example index

page boundaries.) `amgetmulti` and `amgettupple` cannot be used in the same index scan; there are other restrictions too when using `amgetmulti`, as explained in Section 50.3.

```
void
amrescan (IndexScanDesc scan,
         ScanKey key);
```

Restart the given scan, possibly with new scan keys (to continue using the old keys, `NULL` is passed for `key`). Note that it is not possible for the number of keys to be changed. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same. This function is also called by `RelationGetIndexScan()`, so it is used for initial setup of an index scan as well as rescanning.

```
void
amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released.

```
void
ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

```
void
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

By convention, the `pg_proc` entry for an index access method function should show the correct number of arguments, but declare them all as type `internal` (since most of the arguments have types that are not known to SQL, and we don't want users calling the functions directly anyway). The return type is declared as `void`, `internal`, or `boolean` as appropriate. The only exception is `amoptions`, which should be correctly declared as taking `text[]` and `bool` and returning `bytea`. This provision allows client code to execute `amoptions` to test validity of options settings.

## 50.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the *scan keys*. The access method is *not* involved in actually fetching those tuples from the index's parent table, nor in determining whether they pass the scan's time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form *index\_key operator constant*, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The operator family can indicate that the index is *lossy* for a particular operator; this implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system's index-scan machinery will then apply that operator again to the heap tuple to verify whether or not it really should be selected. For non-lossy operators, the index scan must return exactly the set of matching entries, as there is no recheck.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. If entries are returned in sorted order, the access method should set `pg_am.amcanorder` true to indicate that it supports ordered scans. All such access methods must use btree-compatible strategy numbers for their equality and ordering operators.

The `amgettupple` function has a `direction` argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so `amgettupple` must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that advertise they support ordered scans.) After the first call, `amgettupple` must be prepared to advance the scan in either direction from the most recently returned entry.

The access method must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new `ammarkpos` call overrides the previously marked position.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

Instead of using `amgettupple`, an index scan can be done with `amgetmulti` to fetch multiple tuples per call. This can be noticeably more efficient than `amgettupple` because it allows avoiding lock/unlock cycles within the access method. In principle `amgetmulti` should have the same effects as repeated `amgettupple` calls, but we impose several restrictions to simplify matters. In the first place, `amgetmulti` does not take a `direction` argument, and therefore it does not support backwards scan nor intrascan reversal of direction. The access method need not support marking or restoring scan positions during an `amgetmulti` scan, either. (These restrictions cost little since it would be difficult to use these features in an `amgetmulti` scan anyway: adjusting the caller's buffered list of TIDs would be complex.) Finally, `amgetmulti` does not guarantee any locking of the returned tuples, with implications spelled out in Section 50.4.

## 50.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, `REINDEX`, or `VACUUM FULL`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index's own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 50.5.)
- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by `amgettupletuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotNow`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making `ambulkdelete` block on such a pin ensures that `VACUUM` cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an `amgetmulti` index scan, the access method need not guarantee to keep an index pin on any of the returned tuples. (It would be impractical to pin more than the last one anyway.) Therefore it is only safe to use such scans with MVCC-compliant snapshots.

## 50.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets `pg_am.amcanunique` true. (At present, only b-tree supports it.)

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it's okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)
- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)
- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before raising a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no error should be raised. (This case cannot occur during the ordinary scenario of inserting a row that's just been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row's index entry. What's more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

The main limitation of this scheme is that it has no convenient way to support deferred uniqueness checks.

## 50.6. Index Cost Estimation Functions

The `amcostestimate` function is given a list of WHERE clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```
void
amcostestimate (PlannerInfo *root,
```

```

IndexOptInfo *index,
List *indexQuals,
RelOptInfo *outer_rel,
Cost *indexStartupCost,
Cost *indexTotalCost,
Selectivity *indexSelectivity,
double *indexCorrelation);

```

The first four parameters are inputs:

`root`

The planner's information about the query being processed.

`index`

The index being considered.

`indexQuals`

List of index qual clauses (implicitly ANDed); a NIL list indicates no qualifiers are available. Note that the list contains expression trees, not ScanKeys.

`outer_rel`

If the index is being considered for use in a join inner indexscan, the planner's information about the outer side of the join. Otherwise NULL. When non-NULL, some of the qual clauses will be join clauses with this rel rather than being simple restriction clauses. Also, the cost estimator should expect that the index scan will be repeated for each row of the outer rel.

The last four parameters are pass-by-reference outputs:

`*indexStartupCost`

Set to cost of index start-up processing

`*indexTotalCost`

Set to total cost of index processing

`*indexSelectivity`

Set to index selectivity

`*indexCorrelation`

Set to correlation coefficient between index scan order and underlying table's order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of

`cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the `indexQuals` themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but *not* the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The `indexSelectivity` should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy index, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The `indexCorrelation` should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

In the join case, the returned numbers should be averages expected for any one scan of the index.

### Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:  

```
*indexSelectivity = clauselist_selectivity(root, indexQuals,
                                           index->rel->relid, JOIN_INNER);
```
2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as `indexSelectivity` times the number of rows in the index, but it might be more. (Note that the index’s size in pages and rows is available from the `IndexOptInfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just `indexSelectivity` times the index’s size in pages.
4. Compute the index access cost. A generic estimator might do this:

```
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index row.
 * All the costs are assumed to be paid incrementally during the scan.
 */
cost_qual_eval(&index_qual_cost, indexQuals, root);
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
                  (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans in the join case.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adts/selfuncs.c`.

# Chapter 51. GiST Indexes

## 51.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley's GiST Indexing Project web site<sup>1</sup> and Marcel Kornacker's thesis, Access Methods for Next-Generation Database Systems<sup>2</sup>. The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their website<sup>3</sup>.

## 51.2. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer to only implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates ( $<$ ,  $=$ ,  $>$ ), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”? Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement seven user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they're relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

2. <http://www.sai.msu.su/~megeera/postgres/gist/papers/concurrency/access-methods-for-next-generation.pdf.gz>

3. <http://www.sai.msu.su/~megeera/postgres/gist/>

## 51.3. Implementation

There are seven methods that an index operator class for GiST must provide:

`consistent`

Given a predicate `p` on a tree page, and a user query, `q`, this method will return false if it is certain that both `p` and `q` cannot be true for a given data item.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new predicate that is true for all the entries.

`compress`

Converts the data item into a format suitable for physical storage in an index page.

`decompress`

The reverse of the `compress` method. Converts the index representation of the data item into a format that can be manipulated by the database.

`penalty`

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least `penalty` in the tree.

`picksplit`

When a page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

`same`

Returns true if two entries are identical, false otherwise.

## 51.4. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for `tsvector` and `tsquery`) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see `src/backend/access/gist/gistproc.c`). The following `contrib` modules also contain GiST operator classes:

`btree_gist`

B-Tree equivalent functionality for several data types

`cube`

Indexing for multidimensional cubes

`hstore`

Module for storing (key, value) pairs

`intarray`

RD-Tree for one-dimensional array of `int4` values

`ltree`

Indexing for tree-like structures

`pg_trgm`

Text similarity using trigram matching

`seg`

Indexing for “float ranges”

## 51.5. Crash Recovery

Usually, replay of the WAL log is sufficient to restore the integrity of a GiST index following a database crash. However, there are some corner cases in which the index state is not fully rebuilt. The index will still be functionally correct, but there might be some performance degradation. When this occurs, the index can be repaired by `VACUUM`ing its table, or by rebuilding the index using `REINDEX`. In some cases a plain `VACUUM` is not sufficient, and either `VACUUM FULL` or `REINDEX` is needed. The need for one of these procedures is indicated by occurrence of this log message during crash recovery:

```
LOG:  index NNN/NNN/NNN needs VACUUM or REINDEX to finish crash recovery
```

or this log message during routine index insertions:

```
LOG:  index "FOO" needs VACUUM or REINDEX to finish crash recovery
```

If a plain `VACUUM` finds itself unable to complete recovery fully, it will return a notice:

```
NOTICE:  index "FOO" needs VACUUM FULL or REINDEX to finish crash recovery
```

# Chapter 52. GIN Indexes

## 52.1. Introduction

GIN stands for Generalized Inverted Index. It is an index structure storing a set of (key, posting list) pairs, where a “posting list” is a set of rows in which the key occurs. Each indexed value can contain many keys, so the same row ID can appear in multiple posting lists.

It is generalized in the sense that a GIN index does not need to be aware of the operation that it accelerates. Instead, it uses custom strategies defined for particular data types.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website<sup>1</sup>.

## 52.2. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement four user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed values, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

The four methods that an index operator class for GIN must provide are:

`int compare(Datum a, Datum b)`

Compares keys (not indexed values!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second.

`Datum* extractValue(Datum inputValue, int32 *nkeys)`

Returns an array of keys given a value to be indexed. The number of returned keys must be stored into `*nkeys`.

`Datum* extractQuery(Datum query, int32 *nkeys, StrategyNumber n)`

Returns an array of keys given a value to be queried; that is, `query` is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. `n` is the strategy number of the operator within the operator class (see Section 34.14.2). Often, `extractQuery` will need to consult `n` to determine the data type of `query` and the key values that need to be extracted. The number of

---

1. <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin>

returned keys must be stored into `*nkeys`. If number of keys is equal to zero then `extractQuery` should store 0 or -1 into `*nkeys`. 0 means that any row matches the `query` and sequence scan should be produced. -1 means nothing can satisfy `query`. Choice of value should be based on semantics meaning of operation with given strategy number.

`bool consistent(bool check[], StrategyNumber n, Datum query)`

Returns TRUE if the indexed value satisfies the query operator with strategy number `n` (or would satisfy, if the operator is marked `RECHECK` in the operator class). The `check` array has the same length as the number of keys previously returned by `extractQuery` for this query. Each element of the `check` array is TRUE if the indexed value contains the corresponding query key, ie, if `(check[i] == TRUE)` the `i`-th key of the `extractQuery` result array is present in the indexed value. The original `query` datum (not the extracted key array!) is passed in case the `consistent` method needs to consult it.

## 52.3. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of the indexed value (a member of an array, for example) and where each tuple in a leaf page is either a pointer to a B-tree over heap pointers (PT, posting tree), or a list of heap pointers (PL, posting list) if the list is small enough.

## 52.4. GIN tips and tricks

Create vs insert

In most cases, insertion into a GIN index is slow due to the likelihood of many keys being inserted for each value. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn't pay to skimp on work memory during index creation.

`gin_fuzzy_search_limit`

The primary goal of developing GIN indexes was to create support for highly scalable, full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries GIN has a configurable soft upper limit on the number of rows returned, the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ slightly from the specified limit, depending on the query and the quality of the system's random number generator.

## 52.5. Limitations

GIN doesn't support full index scans: because there are often many keys per value, each heap pointer would be returned many times, and there is no easy way to prevent this.

When `extractQuery` returns zero keys, GIN will emit an error. Depending on the operator, a void query might match all, some, or none of the indexed values (for example, every array contains the empty array, but does not overlap the empty array), and GIN cannot determine the correct answer, nor produce a full-index-scan result if it could determine that that was correct.

It is not an error for `extractValue` to return zero keys, but in this case the indexed value will be unrepresented in the index. This is another reason why full index scan is not useful — it would miss such rows.

GIN searches keys only by equality matching. This might be improved in future.

## 52.6. Examples

The PostgreSQL source distribution includes GIN operator classes for `tsvector` and for one-dimensional arrays of all internal types. The following `contrib` modules also contain GIN operator classes:

`hstore`

Module for storing (key, value) pairs

`intarray`

Enhanced support for `int4[]`

`pg_trgm`

Text similarity using trigram matching

# Chapter 53. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

## 53.1. Database File Layout

This section describes the storage format at the level of files and directories.

All the data needed for a database cluster is stored within the cluster's data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in Table 53-1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in PGDATA (although in PostgreSQL 8.0 and later, it is possible to keep them elsewhere).

**Table 53-1. Contents of PGDATA**

Item	Description
PG_VERSION	A file containing the major version number of PostgreSQL
base	Subdirectory containing per-database subdirectories
global	Subdirectory containing cluster-wide tables, such as <code>pg_database</code>
pg_clog	Subdirectory containing transaction commit status data
pg_multixact	Subdirectory containing multitransaction status data (used for shared row locks)
pg_subtrans	Subdirectory containing subtransaction status data
pg_tblspc	Subdirectory containing symbolic links to tablespaces
pg_twophase	Subdirectory containing state files for prepared transactions
pg_xlog	Subdirectory containing WAL (Write Ahead Log) files
postmaster.opts	A file recording the command-line options the server was last started with

Item	Description
<code>postmaster.pid</code>	A lock file recording the current server PID and shared memory segment ID (not present after server shutdown)

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database's OID in `pg_database`. This subdirectory is the default location for the database's files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file, named after the table or index's *filenode* number, which can be found in `pg_class.relfilenode`.

### Caution

Note that while a table's *filenode* often matches its *OID*, this is *not* necessarily the case; some operations, like `TRUNCATE`, `REINDEX`, `CLUSTER` and some forms of `ALTER TABLE`, can change the *filenode* while preserving the *OID*. Avoid assuming that *filenode* and table *OID* are the same.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized *segments*. The first segment's file name is the same as the *filenode*; subsequent segments are named *filenode.1*, *filenode.2*, etc. This arrangement avoids problems on platforms that have file size limitations. The contents of tables and indexes are discussed further in Section 53.3.

A table that has columns with potentially large entries will have an associated *TOAST* table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. `pg_class.reltoastrelid` links from a table to its *TOAST* table, if any. See Section 53.2 for more information.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the `PGDATA/pg_tblspc` directory, which points to the physical tablespace directory (as specified in its `CREATE TABLESPACE` command). The symbolic link is named after the tablespace's *OID*. Inside the physical tablespace directory there is a subdirectory for each database that has elements in the tablespace, named after the database's *OID*. Tables within that directory follow the *filenode* naming scheme. The `pg_default` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/base`. Similarly, the `pg_global` tablespace is not accessed through `pg_tblspc`, but corresponds to `PGDATA/global`.

Temporary files (for operations such as sorting more data than can fit in memory) are created within `PGDATA/base/pgsql_tmp`, or within a `pgsql_tmp` subdirectory of a tablespace directory if a tablespace other than `pg_default` is specified for them. The name of a temporary file has the form `pgsql_tmpPPP.NNN`, where *PPP* is the PID of the owning backend and *NNN* distinguishes different files of that backend.

## 53.2. TOAST

This section provides an overview of *TOAST* (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large

field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”).

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (*varlena*) representation, in which the first 32-bit word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the representation. All the C-level functions supporting a TOAST-able data type must be careful to handle TOASTed input values. (This is normally done by invoking `PG_DETOAST_DATUM` before doing anything with an input value, but in some cases more efficient approaches are possible.)

TOAST usurps two bits of the *varlena* length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ( $2^{30}$  - 1 bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits give the total datum size (including length byte) in bytes. As a special case, if the remaining bits are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data stored in a separate TOAST table. (The size of a TOAST pointer is given in the second byte of the datum.) Values with single-byte headers aren’t aligned on any particular boundary, either. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the *varlena* header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s `pg_class.reltoastrelid` entry. Out-of-line TOASTed values are kept in the TOAST table, as described in more detail below.

The compression technique used is a fairly simple and very fast member of the LZ family of compression techniques. See `src/backend/utils/adts/pg_lzcompress.c` for the details.

Out-of-line values are divided (after compression if used) into chunks of at most `TOAST_MAX_CHUNK_SIZE` bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table for the owning table. Every TOAST table has the columns `chunk_id` (an OID identifying the particular TOASTed value), `chunk_seq` (a sequence number for the chunk within its value), and `chunk_data` (the actual data of the chunk). A unique index on `chunk_id` and `chunk_seq` provides fast retrieval of the values. A pointer datum representing an out-of-line TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its `chunk_id`). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and actual stored size (different if compression was applied). Allowing for the *varlena* header bytes, the total size of a TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST code is triggered only when a row value to be stored in a table is wider than `TOAST_TUPLE_THRESHOLD` bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than `TOAST_TUPLE_TARGET` bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the

out-of-line values change.

The TOAST code recognizes four different strategies for storing TOAST-able columns:

- `PLAIN` prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- `EXTENDED` allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- `EXTERNAL` allows out-of-line storage but not compression. Use of `EXTERNAL` will make substring operations on wide `text` and `bytea` columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- `MAIN` allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with `ALTER TABLE SET STORAGE`.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

## 53.3. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes.<sup>1</sup> Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a *byte* is assumed to contain 8 bits. In addition, the term *item* refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of *pages* of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a *metapage* holding control information, and there can be different types of pages within the index, depending on the index access method.

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn't follow the item layout rules.

Table 53-2 shows the overall layout of a page. There are five parts to each page.

**Table 53-2. Overall Page Layout**

Item	Description
PageHeaderData	24 bytes long. Contains general information about the page, including free space pointers.
ItemIdData	Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.
Free space	The unallocated space. New item pointers are allocated from the start of this area, new items from the end.
Items	The actual items themselves.
Special space	Index access method specific data. Different methods store different data. Empty in ordinary tables.

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 53-3. The first two fields track the most recent WAL entry related to this page. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (`pd_lower`, `pd_upper`, and `pd_special`). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, `pd_pagesize_version`, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

**Table 53-3. PageHeaderData Layout**

Field	Type	Length	Description
<code>pd_lsn</code>	XLogRecPtr	8 bytes	LSN: next byte after last byte of xlog record for last change to this page
<code>pd_tli</code>	uint16	2 bytes	TimeLineID of last change (only its lowest 16 bits)
<code>pd_flags</code>	uint16	2 bytes	Flag bits
<code>pd_lower</code>	LocationIndex	2 bytes	Offset to start of free space
<code>pd_upper</code>	LocationIndex	2 bytes	Offset to end of free space

Field	Type	Length	Description
pd_special	LocationIndex	2 bytes	Offset to start of special space
pd_pagesize_version	uint16	2 bytes	Page size and layout version number information
pd_prune_xid	TransactionId	4 bytes	Oldest unpruned XMAX on page, or zero if none

All the details can be found in `src/include/storage/bufpage.h`.

Following the page header are item identifiers (`ItemIdData`), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at `pd_lower`, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (`ItemPointer`, also known as `CTID`) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named `HeapTupleHeaderData`, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting `pd_special` to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 53-4. The actual user data (columns of the row) begins at the offset indicated by `t_hoff`, which must always be a multiple of the `MAXALIGN` distance for the platform. The null bitmap is only present if the `HEAP_HASNULL` bit is set in `t_infomask`. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, `t_natts` bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the `HEAP_HASOID` bit is set in `t_infomask`. If present, it appears just before the `t_hoff` boundary. Any padding needed to make `t_hoff` a `MAXALIGN` multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

**Table 53-4. HeapTupleHeaderData Layout**

Field	Type	Length	Description
t_xmin	TransactionId	4 bytes	insert XID stamp
t_xmax	TransactionId	4 bytes	delete XID stamp

Field	Type	Length	Description
t_cid	CommandId	4 bytes	insert and/or delete CID stamp (overlays with t_xvac)
t_xvac	TransactionId	4 bytes	XID for VACUUM operation moving a row version
t_ctid	ItemPointerData	6 bytes	current TID of this or newer row version
t_infomask2	int16	2 bytes	number of attributes, plus various flag bits
t_infomask	uint16	2 bytes	various flag bits
t_hoff	uint8	1 byte	offset to user data

All the details can be found in `src/include/access/htup.h`.

Interpreting the actual data can only be done with information obtained from other tables, mostly `pg_attribute`. The key values needed to identify field locations are `attlen` and `attalign`. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions `heap_getattr`, `fastgetattr` and `heap_getsysattr`.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it's a variable length field (`attlen = -1`) then it's a bit more complicated. All variable-length datatypes share the common header structure `struct varlena`, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 53.2).

# Chapter 54. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named `genbki.sh`, which reads some specially formatted C header files in the `src/include/catalog/` directory of the source tree. The created BKI file is called `postgres.bki` and is normally installed in the `share` subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

## 54.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

## 54.2. BKI Commands

```
create [bootstrap] [shared_relation] [without_oids] tablename tableoid (name1 = type1  
[, name2 = type2, ...])
```

Create a table named *tablename*, and having the OID *tableoid*, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char` (1 byte), `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `int2vector`, `oidvector`, `_int4` (array), `_text` (array), `_oid` (array), `_char` (array), `_aclitem` (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only

these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc., for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc themselves.

The table is created as shared if `shared_relation` is specified. It will have OIDs unless `without_oids` is specified.

`open tablename`

Open the table named `tablename` for insertion of data. Any currently open table is closed.

`close [tablename]`

Close the open table. The name of the table can be given as a cross-check, but this is not required.

`insert [OID = oid_value] ( value1 value2 ... )`

Insert a new row into the open table using `value1`, `value2`, etc., for its column values and `oid_value` for its OID. If `oid_value` is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word `_null_`. Values containing spaces must be double quoted.

`declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [ , ... ] )`

Create an index named `indexname`, having OID `indexoid`, on the table named `tablename`, using the `amname` access method. The fields to index are called `name1`, `name2` etc., and the operator classes to use are `opclass1`, `opclass2` etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

`declare toast toasttableoid toastindexoid on tablename`

Create a TOAST table for the table named `tablename`. The TOAST table is assigned OID `toasttableoid` and its index is assigned OID `toastindexoid`. As with `declare index`, filling of the index is postponed.

`build indices`

Fill in the indices that have previously been declared.

## 54.3. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. `close`
4. Repeat for the other critical tables.
5. `create` (without `bootstrap`) a noncritical table
6. `open`
7. `insert` desired data
8. `close`
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. `build indices`

There are doubtless other, undocumented ordering dependencies.

## 54.4. Example

The following sequence of commands will create the table `test_table` with OID 420, having two columns `cola` and `colb` of type `int4` and `text`, respectively, and insert two rows into the table:

```
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```

# Chapter 55. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

## 55.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

QUERY PLAN

```
-----  
Seq Scan on tenk1  (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
 relpages | reltuples  
-----+-----  
      358 |      10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In this case the values are correct so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

QUERY PLAN

```
-----  
Bitmap Heap Scan on tenk1  (cost=24.06..394.64 rows=1007 width=244)  
  Recheck Cond: (unique1 < 1000)  
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
```

```
Index Cond: (unique1 < 1000)
```

The planner examines the `WHERE` clause condition and looks up the selectivity function for the operator `<` in `pg_operator`. This is held in the column `oprrest`, and the entry in this case is `scalarlttsel`. The `scalarlttsel` function retrieves the histogram for `unique1` from `pg_statistics`. For manual queries it is more convenient to look in the simpler `pg_stats` view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';

          histogram_bounds
-----
{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}
```

Next the fraction of the histogram occupied by “`< 1000`” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count *part* of it and *all* of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

```
selectivity = (1 + (1000 - bucket[2].min)/(bucket[2].max - bucket[2].min))/num_buckets
             = (1 + (1000 - 993)/(1997 - 993))/10
             = 0.100697
```

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of `tenk1`:

```
rows = rel_cardinality * selectivity
      = 10000 * 0.100697
      = 1007 (rounding off)
```

Next let’s consider an example with an equality condition in its `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE string1 = 'CRAAAA';

          QUERY PLAN
-----
Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244)
  Filter: (string1 = 'CRAAAA'::name)
```

Again the planner examines the `WHERE` clause condition and looks up the selectivity function for `=`, which is `eqsel`. For equality estimation the histogram is not useful; instead the list of *most common values* (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='string1';

null_frac      | 0
n_distinct     | 676
```

```

most_common_vals | {EJAAAA,BBAAAA,CRAAAA,FCAAAA,FEAAAA,GSAAAA,JOAAAA,MCAAAA,NAAAAA,WGAAAA}
most_common_freqs | {0.00333333,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003,0.003}

```

Since `CRAAAA` appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

```

selectivity = mcf[3]
             = 0.003

```

As before, the estimated number of rows is just the product of this with the cardinality of `tenk1`:

```

rows = 10000 * 0.003
      = 30

```

Now consider the same query, but with a constant that is not in the MCV list:

```
EXPLAIN SELECT * FROM tenk1 WHERE string1 = 'xxx';
```

#### QUERY PLAN

```

-----
Seq Scan on tenk1  (cost=0.00..483.00 rows=15 width=244)
  Filter: (string1 = 'xxx'::name)

```

This is quite a different problem: how to estimate the selectivity when the value is *not* in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

```

selectivity = (1 - sum(mvf))/(num_distinct - num_mcv)
             = (1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 +
                    0.003 + 0.003 + 0.003 + 0.003))/(676 - 10)
             = 0.0014559

```

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of *other* distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don't have to worry about those (otherwise we'd subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

```

rows = 10000 * 0.0014559
      = 15  (rounding off)

```

The previous example with `unique1 < 1000` was an oversimplification of what `scalarltsel` really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since `unique1` is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and *the histogram does not include the portion of the column population represented by the MCVs*. We do things this way because it allows more precise estimation. In this situation `scalarltsel` directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity

within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE string1 < 'IAAAAA';
```

QUERY PLAN

```
-----
Seq Scan on tenk1  (cost=0.00..483.00 rows=3077 width=244)
  Filter: (string1 < 'IAAAAA'::name)
```

We already saw the MCV information for `string1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='string1';
```

histogram\_bounds

```
-----
{AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `string1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
             = 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
             = 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we'd have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
             = 0.01833333 + 0.298387 * 0.96966667
             = 0.307669
```

```
rows        = 10000 * 0.307669
             = 3077  (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let's consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND string1 = 'xxx';
```

QUERY PLAN

```

Bitmap Heap Scan on tenk1  (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (string1 = 'xxx'::name)
-> Bitmap Index Scan on tenk1_unique1  (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)

```

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

```

selectivity = selectivity(unique1 < 1000) * selectivity(string1 = 'xxx')
              = 0.100697 * 0.0014559
              = 0.0001466

rows        = 10000 * 0.0001466
              = 1    (rounding off)

```

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

```

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

```

#### QUERY PLAN

```

-----
Nested Loop  (cost=4.64..456.23 rows=50 width=488)
-> Bitmap Heap Scan on tenk1 t1  (cost=4.64..142.17 rows=50 width=244)
    Recheck Cond: (unique1 < 50)
    -> Bitmap Index Scan on tenk1_unique1  (cost=0.00..4.63 rows=50 width=0)
        Index Cond: (unique1 < 50)
-> Index Scan using tenk2_unique2 on tenk2 t2  (cost=0.00..6.27 rows=1 width=244)
    Index Cond: (t2.unique2 = t1.unique2)

```

The restriction on `tenk1, unique1 < 50`, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the `unique1` histogram:

```

selectivity = (0 + (50 - bucket[1].min)/(bucket[1].max - bucket[1].min))/num_buckets
              = (0 + (50 - 0)/(993 - 0))/10
              = 0.005035

rows        = 10000 * 0.005035
              = 50    (rounding off)

```

The restriction for the join is `t2.unique2 = t1.unique2`. The operator is just our familiar `=`, however the selectivity function is obtained from the `oprjoin` column of `pg_operator`, and is `eqjoinsel`. `eqjoinsel` looks up the statistical information for both `tenk2` and `tenk1`:

```

SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';

```

tablename	null_frac	n_distinct	most_common_vals
tenk1	0	-1	
tenk2	0	-1	

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

```
selectivity = (1 - null_frac1) * (1 - null_frac2) * min(1/num_distinct1, 1/num_distinct2)
             = (1 - 0) * (1 - 0) / max(10000, 10000)
             = 0.0001
```

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

```
rows = (outer_cardinality * inner_cardinality) * selectivity
      = (50 * 10000) * 0.0001
      = 50
```

Had there been MCV lists for the two columns, `eqjoinse1` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the `EXPLAIN` output that the estimate of join rows comes from `50 * 1`, that is, the number of outer rows times the estimated number of rows obtained by each inner indexscan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to roundoff error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any `WHERE` clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adt/selfuncs.c`.

## **VIII. Appendixes**

# Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard's conventions for "SQLSTATE" codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code can still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 8.3.1. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a "standard" error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The PL/pgSQL condition name for each error code is the same as the phrase shown in the table, with underscores substituted for spaces. For example, code 22012, DIVISION BY ZERO, has condition name DIVISION\_BY\_ZERO. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

**Table A-1. PostgreSQL Error Codes**

Error Code	Meaning	Constant
<b>Class 00 — Successful Completion</b>		
00000	SUCCESSFUL COMPLETION	successful_completion
<b>Class 01 — Warning</b>		
01000	WARNING	warning
0100C	DYNAMIC RESULT SETS RETURNED	dynamic_result_sets_returned
01008	IMPLICIT ZERO BIT PADDING	implicit_zero_bit_padding
01003	NULL VALUE ELIMINATED IN SET FUNCTION	null_value_eliminated_in_set_function
01007	PRIVILEGE NOT GRANTED	privilege_not_granted
01006	PRIVILEGE NOT REVOKED	privilege_not_revoked
01004	STRING DATA RIGHT TRUNCATION	string_data_right_truncation
01P01	DEPRECATED FEATURE	deprecated_feature
<b>Class 02 — No Data (this is also a warning class per the SQL standard)</b>		
02000	NO DATA	no_data
02001	NO ADDITIONAL DYNAMIC RESULT SETS RETURNED	no_additional_dynamic_result_sets_returned

Error Code	Meaning	Constant
<b>Class 03 — SQL Statement Not Yet Complete</b>		
03000	SQL STATEMENT NOT YET COMPLETE	sql_statement_not_yet_complete
<b>Class 08 — Connection Exception</b>		
08000	CONNECTION EXCEPTION	connection_exception
08003	CONNECTION DOES NOT EXIST	connection_does_not_exist
08006	CONNECTION FAILURE	connection_failure
08001	SQLCLIENT UNABLE TO ESTABLISH SQLCONNECTION	sqlclient_unable_to_establish_sqlconnection
08004	SQLSERVER REJECTED ESTABLISHMENT OF SQLCONNECTION	sqlserver_rejected_establishment_of_sqlconnection
08007	TRANSACTION RESOLUTION UNKNOWN	transaction_resolution_unknown
08P01	PROTOCOL VIOLATION	protocol_violation
<b>Class 09 — Triggered Action Exception</b>		
09000	TRIGGERED ACTION EXCEPTION	triggered_action_exception
<b>Class 0A — Feature Not Supported</b>		
0A000	FEATURE NOT SUPPORTED	feature_not_supported
<b>Class 0B — Invalid Transaction Initiation</b>		
0B000	INVALID TRANSACTION INITIATION	invalid_transaction_initiation
<b>Class 0F — Locator Exception</b>		
0F000	LOCATOR EXCEPTION	locator_exception
0F001	INVALID LOCATOR SPECIFICATION	invalid_locator_specification
<b>Class 0L — Invalid Grantor</b>		
0L000	INVALID GRANTOR	invalid_grantor
0LP01	INVALID GRANT OPERATION	invalid_grant_operation
<b>Class 0P — Invalid Role Specification</b>		
0P000	INVALID ROLE SPECIFICATION	invalid_role_specification
<b>Class 21 — Cardinality Violation</b>		
21000	CARDINALITY VIOLATION	cardinality_violation
<b>Class 22 — Data Exception</b>		
22000	DATA EXCEPTION	data_exception

Error Code	Meaning	Constant
2202E	ARRAY SUBSCRIPT ERROR	array_subscript_error
22021	CHARACTER NOT IN REPERTOIRE	character_not_in_repertoire
22008	DATETIME FIELD OVERFLOW	datetime_field_overflow
22012	DIVISION BY ZERO	division_by_zero
22005	ERROR IN ASSIGNMENT	error_in_assignment
2200B	ESCAPE CHARACTER CONFLICT	escape_character_conflict
22022	INDICATOR OVERFLOW	indicator_overflow
22015	INTERVAL FIELD OVERFLOW	interval_field_overflow
2201E	INVALID ARGUMENT FOR LOGARITHM	invalid_argument_for_logarithm
2201F	INVALID ARGUMENT FOR POWER FUNCTION	invalid_argument_for_power_function
2201G	INVALID ARGUMENT FOR WIDTH BUCKET FUNCTION	invalid_argument_for_width_bucket_function
22018	INVALID CHARACTER VALUE FOR CAST	invalid_character_value_for_cast
22007	INVALID DATETIME FORMAT	invalid_datetime_format
22019	INVALID ESCAPE CHARACTER	invalid_escape_character
2200D	INVALID ESCAPE OCTET	invalid_escape_octet
22025	INVALID ESCAPE SEQUENCE	invalid_escape_sequence
22P06	NONSTANDARD USE OF ESCAPE CHARACTER	nonstandard_use_of_escape_character
22010	INVALID INDICATOR PARAMETER VALUE	invalid_indicator_parameter_value
22020	INVALID LIMIT VALUE	invalid_limit_value
22023	INVALID PARAMETER VALUE	invalid_parameter_value
2201B	INVALID REGULAR EXPRESSION	invalid_regular_expression
22009	INVALID TIME ZONE DISPLACEMENT VALUE	invalid_time_zone_displacement_value
2200C	INVALID USE OF ESCAPE CHARACTER	invalid_use_of_escape_character

Error Code	Meaning	Constant
2200G	MOST SPECIFIC TYPE MISMATCH	most_specific_type_mismatch
22004	NULL VALUE NOT ALLOWED	null_value_not_allowed
22002	NULL VALUE NO INDICATOR PARAMETER	null_value_no_indicator_parameter
22003	NUMERIC VALUE OUT OF RANGE	numeric_value_out_of_range
22026	STRING DATA LENGTH MISMATCH	string_data_length_mismatch
22001	STRING DATA RIGHT TRUNCATION	string_data_right_truncation
22011	SUBSTRING ERROR	substring_error
22027	TRIM ERROR	trim_error
22024	UNTERMINATED C STRING	unterminated_c_string
2200F	ZERO LENGTH CHARACTER STRING	zero_length_character_string

# Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

## B.1. Date/Time Input Interpretation

The date/time type inputs are all decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
  - a. If the numeric token contains a colon (:), this is a time string. Include all subsequent digits and colons.
  - b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., *America/New\_York*).
  - c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
  - d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.
2. If the token is a text string, match up with possible strings:
  - a. Do a binary-search table lookup for the token as a time zone abbreviation.
  - b. If not found, do a similar binary-search table lookup to match the token as either a special string (e.g., *today*), day (e.g., *Thursday*), month (e.g., *January*), or noise word (e.g., *at*, *on*).
  - c. If still not found, throw an error.
3. When the token is a number or number field:
  - a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is *YYYYMMDD* or *YYMMDD*.
  - b. If the token is three digits and a year has already been read, then interpret as day of year.
  - c. If four or six digits and a year has already been read, then interpret as a time (*HHMM* or *HHMMSS*).

- d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
  - e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)
  5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

**Tip:** Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

## B.2. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

**Table B-1. Month Names**

Month	Abbreviations
January	Jan
February	Feb
March	Mar
April	Apr
May	
June	Jun
July	Jul
August	Aug
September	Sep, Sept
October	Oct
November	Nov
December	Dec

Table B-2 shows the tokens that are recognized as names of days of the week.

**Table B-2. Day of the Week Names**

Day	Abbreviations
Sunday	Sun
Monday	Mon

Day	Abbreviations
Tuesday	Tue, Tues
Wednesday	Wed, Weds
Thursday	Thu, Thur, Thurs
Friday	Fri
Saturday	Sat

Table B-3 shows the tokens that serve various modifier purposes.

**Table B-3. Date/Time Field Modifiers**

Identifier	Description
ABSTIME	Ignored
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Day
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time

The key word `ABSTIME` is ignored for historical reasons: In very old releases of PostgreSQL, invalid values of type `abstime` were emitted as `Invalid Abstime`. This is no longer the case however and this key word will likely be dropped in a future release.

## B.3. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The `timezone_abbreviations` run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

`timezone_abbreviations` can be set to any file name found in `.../share/timezonesets/`, if the file's name is entirely alphabetic. (The prohibition against non-alphabetic characters in `timezone_abbreviations` prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with `#`. Non-comment lines must have one of these formats:

```
time_zone_name offset
time_zone_name offset D
@INCLUDE file_name
@OVERRIDE
```

A `time_zone_name` is just the abbreviation being defined. The `offset` is the zone's offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. `D` indicates that the zone name represents local daylight-savings time rather than standard time. Since all known time zone offsets are on 15 minute boundaries, the number of seconds has to be a multiple of 900.

The `@INCLUDE` syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The `@OVERRIDE` syntax indicates that subsequent entries in the file can override previous entries (i.e., entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file `Default` contains all the non-conflicting time zone abbreviations for most of the world. Additional files `Australia` and `India` are provided for those regions: these files first include the `Default` file and then add or modify timezones as needed.

For reference purposes, a standard installation also contains files `Africa.txt`, `America.txt`, etc, containing information about every time zone abbreviation known to be in use according to the `zic` timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as `timezone_abbreviations` settings, because of the dot embedded in their names.

**Note:** If an error occurs while reading the time zone data sets, no new value is applied but the old set is kept. If the error occurs while starting the database, startup fails.

### Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the `Australia` configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.

### Caution

If you modify files in `.../share/timezonesets/`, it is up to you to make backups — a normal database dump will not include this directory.

## B.4. History of Units

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as  $365 \frac{1}{4}$  days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as  $365 + 97 / 400$  days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one day with respect to the Gregorian calendar.

The approximation  $365+97/400$  is achieved by having 97 leap years every 400 years, using the following rules:

Every year divisible by 4 is a leap year.

However, every year divisible by 100 is not a leap year.

However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that 15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal, and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to change, and the Greek Orthodox countries didn't change until the start of the 20th century. The reform was observed by Great Britain and Dominions (including what is now the USA) in 1752. Thus 2 September 1752 was followed by 14 September 1752. This is why Unix systems have the `cal` program produce the following:

```
$ cal 9 1752
      September 1752
S  M Tu  W Th  F  S
           1  2 14 15 16
17 18 19 20 21 22 23
24 25 26 27 28 29 30
```

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime value’s are constrained by the natural rules for dates and times according to the Gregorian calendar”. Dates between 1582-10-05 and 1582-10-14, although eliminated in some countries by Papal fiat, conform to “natural rules” and are hence valid dates. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The “Julian Date” is unrelated to the “Julian calendar”. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called *the* Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 1 January 4713 BC to noon UTC on 2 January 4713 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses them for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.

# Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 8.3.1. Background information can be found in Section 4.1.1.

SQL distinguishes between *reserved* and *non-reserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

## Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent full update appearing in 2003, with a partial update appearing in 2006. The 2003 version is referred to as ISO/IEC 9075:2003, or simply as SQL:2003. The versions prior to that were SQL:1999 and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. The PostgreSQL project is not represented in the ISO/IEC 9075 Working Group during the preparation of the SQL standard releases, but even so, many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The SQL:2003 standard is also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

PostgreSQL covers parts 1, 2, 11, and 14. Part 3 is similar to the ODBC interface, and part 4 is similar to the PL/pgSQL programming language, but exact conformance is not specifically intended or verified in either case.

PostgreSQL supports most of the major features of SQL:2003. Out of 164 mandatory features required for full Core conformance, PostgreSQL conforms to at least 150. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2003.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2003 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

**Note:** Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

Identifier	Package	Description	Comment
B012		Embedded C	
B021		Direct SQL	
E011	Core	Numeric data types	
E011-01	Core	INTEGER and SMALLINT data types	
E011-02	Core	REAL, DOUBLE PRECISION, and FLOAT data types	
E011-03	Core	DECIMAL and NUMERIC data types	
E011-04	Core	Arithmetic operators	
E011-05	Core	Numeric comparison	
E011-06	Core	Implicit casting among the numeric data types	
E021	Core	Character data types	
E021-01	Core	CHARACTER data type	
E021-02	Core	CHARACTER VARYING data type	
E021-03	Core	Character literals	

Identifier	Package	Description	Comment
E021-04	Core	CHARACTER_LENGTH function	Trims trailing spaces from CHARACTER values before counting
E021-05	Core	OCTET_LENGTH function	
E021-06	Core	SUBSTRING function	
E021-07	Core	Character concatenation	
E021-08	Core	UPPER and LOWER functions	
E021-09	Core	TRIM function	
E021-10	Core	Implicit casting among the character string types	
E021-11	Core	POSITION function	
E021-12	Core	Character comparison	
E031	Core	Identifiers	
E031-01	Core	Delimited identifiers	
E031-02	Core	Lower case identifiers	
E031-03	Core	Trailing underscore	
E051	Core	Basic query specification	
E051-01	Core	SELECT DISTINCT	
E051-02	Core	GROUP BY clause	
E051-04	Core	GROUP BY can contain columns not in <select list>	
E051-05	Core	Select list items can be renamed	AS is required
E051-06	Core	HAVING clause	
E051-07	Core	Qualified * in select list	
E051-08	Core	Correlation names in the FROM clause	
E051-09	Core	Rename columns in the FROM clause	
E061	Core	Basic predicates and search conditions	
E061-01	Core	Comparison predicate	
E061-02	Core	BETWEEN predicate	
E061-03	Core	IN predicate with list of values	
E061-04	Core	LIKE predicate	

Identifier	Package	Description	Comment
E061-05	Core	LIKE predicate ESCAPE clause	
E061-06	Core	NULL predicate	
E061-07	Core	Quantified comparison predicate	
E061-08	Core	EXISTS predicate	
E061-09	Core	Subqueries in comparison predicate	
E061-11	Core	Subqueries in IN predicate	
E061-12	Core	Subqueries in quantified comparison predicate	
E061-13	Core	Correlated subqueries	
E061-14	Core	Search condition	
E071	Core	Basic query expressions	
E071-01	Core	UNION DISTINCT table operator	
E071-02	Core	UNION ALL table operator	
E071-03	Core	EXCEPT DISTINCT table operator	
E071-05	Core	Columns combined via table operators need not have exactly the same data type	
E071-06	Core	Table operators in subqueries	
E081-01	Core	SELECT privilege	
E081-02	Core	DELETE privilege	
E081-03	Core	INSERT privilege at the table level	
E081-04	Core	UPDATE privilege at the table level	
E081-06	Core	REFERENCES privilege at the table level	
E081-08	Core	WITH GRANT OPTION	
E081-10	Core	EXECUTE privilege	
E091	Core	Set functions	
E091-01	Core	AVG	
E091-02	Core	COUNT	

Identifier	Package	Description	Comment
E091-03	Core	MAX	
E091-04	Core	MIN	
E091-05	Core	SUM	
E091-06	Core	ALL quantifier	
E091-07	Core	DISTINCT quantifier	
E101	Core	Basic data manipulation	
E101-01	Core	INSERT statement	
E101-03	Core	Searched UPDATE statement	
E101-04	Core	Searched DELETE statement	
E111	Core	Single row SELECT statement	
E121-01	Core	DECLARE CURSOR	
E121-02	Core	ORDER BY columns need not be in select list	
E121-03	Core	Value expressions in ORDER BY clause	
E121-04	Core	OPEN statement	
E121-08	Core	CLOSE statement	
E121-10	Core	FETCH statement implicit NEXT	
E121-17	Core	WITH HOLD cursors	
E131	Core	Null value support (nulls in lieu of values)	
E141	Core	Basic integrity constraints	
E141-01	Core	NOT NULL constraints	
E141-02	Core	UNIQUE constraints of NOT NULL columns	
E141-03	Core	PRIMARY KEY constraints	
E141-04	Core	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	
E141-06	Core	CHECK constraints	
E141-07	Core	Column defaults	
E141-08	Core	NOT NULL inferred on PRIMARY KEY	

Identifier	Package	Description	Comment
E141-10	Core	Names in a foreign key can be specified in any order	
E151	Core	Transaction support	
E151-01	Core	COMMIT statement	
E151-02	Core	ROLLBACK statement	
E152	Core	Basic SET TRANSACTION statement	
E152-01	Core	SET TRANSACTION statement: ISOLATION LEVEL SERIALIZABLE clause	
E152-02	Core	SET TRANSACTION statement: READ ONLY and READ WRITE clauses	
E161	Core	SQL comments using leading double minus	
E171	Core	SQLSTATE support	
F021	Core	Basic information schema	
F021-01	Core	COLUMNS view	
F021-02	Core	TABLES view	
F021-03	Core	VIEWS view	
F021-04	Core	TABLE_CONSTRAINTS view	
F021-05	Core	REFERENTIAL_CONSTRAINTS view	
F021-06	Core	CHECK_CONSTRAINTS view	
F031	Core	Basic schema manipulation	
F031-01	Core	CREATE TABLE statement to create persistent base tables	
F031-02	Core	CREATE VIEW statement	
F031-03	Core	GRANT statement	

Identifier	Package	Description	Comment
F031-04	Core	ALTER TABLE statement: ADD COLUMN clause	
F031-13	Core	DROP TABLE statement: RESTRICT clause	
F031-16	Core	DROP VIEW statement: RESTRICT clause	
F031-19	Core	REVOKE statement: RESTRICT clause	
F032		CASCADE drop behavior	
F033		ALTER TABLE statement: DROP COLUMN clause	
F034		Extended REVOKE statement	
F034-01		REVOKE statement performed by other than the owner of a schema object	
F034-02		REVOKE statement: GRANT OPTION FOR clause	
F034-03		REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION	
F041	Core	Basic joined table	
F041-01	Core	Inner join (but not necessarily the INNER keyword)	
F041-02	Core	INNER keyword	
F041-03	Core	LEFT OUTER JOIN	
F041-04	Core	RIGHT OUTER JOIN	
F041-05	Core	Outer joins can be nested	
F041-07	Core	The inner table in a left or right outer join can also be used in an inner join	

Identifier	Package	Description	Comment
F041-08	Core	All comparison operators are supported (rather than just =)	
F051	Core	Basic date and time	
F051-01	Core	DATE data type (including support of DATE literal)	
F051-02	Core	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	
F051-03	Core	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	
F051-04	Core	Comparison predicate on DATE, TIME, and TIMESTAMP data types	
F051-05	Core	Explicit CAST between datetime types and character string types	
F051-06	Core	CURRENT_DATE	
F051-07	Core	LOCALTIME	
F051-08	Core	LOCALTIMESTAMP	
F052	Enhanced datetime facilities	Intervals and datetime arithmetic	
F053		OVERLAPS predicate	
F081	Core	UNION and EXCEPT in views

# Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the CVS logs for each release. The `pgsql-committers` email list<sup>1</sup> contains all source code changes as well. There is also a web interface<sup>2</sup> that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

## E.1. Release 8.3.1

**Release date:** 2008-03-17

This release contains a variety of fixes from 8.3.0.

### E.1.1. Migration to Version 8.3.1

A dump/restore is not required for those running 8.3.X. However, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the Windows locale issue described below.

### E.1.2. Changes

- Fix character string comparison for Windows locales that consider different character combinations as equal (Tom)

This fix applies only on Windows and only when using UTF-8 database encoding. The same fix was made for all other cases over two years ago, but Windows with UTF-8 uses a separate code path that was not updated. If you are using a locale that considers some non-identical strings as equal, you may need to `REINDEX` to fix existing indexes on textual columns.

- Repair corner-case bugs in `VACUUM FULL` (Tom)

A potential deadlock between concurrent `VACUUM FULL` operations on different system catalogs was introduced in 8.2. This has now been corrected. 8.3 made this worse because the deadlock could occur within a critical code section, making it a `PANIC` rather than just `ERROR` condition.

---

1. <http://archives.postgresql.org/pgsql-committers/>  
2. <http://developer.postgresql.org/cvsweb.cgi/pgsql/>

Also, a `VACUUM FULL` that failed partway through vacuuming a system catalog could result in cache corruption in concurrent database sessions.

Another `VACUUM FULL` bug introduced in 8.3 could result in a crash or out-of-memory report when dealing with pages containing no live tuples.

- Fix misbehavior of foreign key checks involving `character` or `bit` columns (Tom)

If the referencing column were of a different but compatible type (for instance `varchar`), the constraint was enforced incorrectly.

- Avoid needless deadlock failures in no-op foreign-key checks (Stephan Szabo, Tom)
- Fix possible core dump when re-planning a prepared query (Tom)

This bug affected only protocol-level prepare operations, not `SQL PREPARE`, and so tended to be seen only with JDBC, DBI, and other client-side drivers that use prepared statements heavily.

- Fix possible failure when re-planning a query that calls an SPI-using function (Tom)
- Fix failure in row-wise comparisons involving columns of different datatypes (Tom)
- Fix longstanding `LISTEN/NOTIFY` race condition (Tom)

In rare cases a session that had just executed a `LISTEN` might not get a notification, even though one would be expected because the concurrent transaction executing `NOTIFY` was observed to commit later.

A side effect of the fix is that a transaction that has executed a not-yet-committed `LISTEN` command will not see any row in `pg_listener` for the `LISTEN`, should it choose to look; formerly it would have. This behavior was never documented one way or the other, but it is possible that some applications depend on the old behavior.

- Disallow `LISTEN` and `UNLISTEN` within a prepared transaction (Tom)

This was formerly allowed but trying to do it had various unpleasant consequences, notably that the originating backend could not exit as long as an `UNLISTEN` remained uncommitted.

- Disallow dropping a temporary table within a prepared transaction (Heikki)

This was correctly disallowed by 8.1, but the check was inadvertently broken in 8.2 and 8.3.

- Fix rare crash when an error occurs during a query using a hash index (Heikki)
- Fix incorrect comparison of `tsquery` values (Teodor)
- Fix incorrect behavior of `LIKE` with non-ASCII characters in single-byte encodings (Rolf Jentsch)
- Disable `xmlvalidate` (Tom)

This function should have been removed before 8.3 release, but was inadvertently left in the source code. It poses a small security risk since unprivileged users could use it to read the first few characters of any file accessible to the server.

- Fix memory leaks in certain usages of set-returning functions (Neil)
- Make `encode(bytea, 'escape')` convert all high-bit-set byte values into `\nnn` octal escape sequences (Tom)

This is necessary to avoid encoding problems when the database encoding is multi-byte. This change could pose compatibility issues for applications that are expecting specific results from `encode`.

- Fix input of datetime values for February 29 in years BC (Tom)

The former coding was mistaken about which years were leap years.

- Fix “unrecognized node type” error in some variants of `ALTER OWNER` (Tom)
- Avoid tablespace permissions errors in `CREATE TABLE LIKE INCLUDING INDEXES` (Tom)
- Ensure `pg_stat_activity.waiting` flag is cleared when a lock wait is aborted (Tom)
- Fix handling of process permissions on Windows Vista (Dave, Magnus)

In particular, this fix allows starting the server as the Administrator user.

- Update time zone data files to tzdata release 2008a (in particular, recent Chile changes); adjust timezone abbreviation `VET` (Venezuela) to mean UTC-4:30, not UTC-4:00 (Tom)
- Fix `ecpg` problems with arrays (Michael)
- Fix `pg_ctl` to correctly extract the postmaster’s port number from command-line options (Itagaki Takahiro, Tom)

Previously, `pg_ctl start -w` could try to contact the postmaster on the wrong port, leading to bogus reports of startup failure.

- Use `-fwrapv` to defend against possible misoptimization in recent gcc versions (Tom)

This is known to be necessary when building PostgreSQL with gcc 4.3 or later.

- Enable building `contrib/uuid-openssl` with MSVC (Hiroshi Saito)

## E.2. Release 8.3

**Release date:** 2008-02-04

### E.2.1. Overview

With significant new functionality and performance enhancements, this release represents a major leap forward for PostgreSQL. This was made possible by a growing community that has dramatically accelerated the pace of development. This release adds the following major features:

- Full text search is integrated into the core database system
- Support for the SQL/XML standard, including new operators and an `XML` data type
- Enumerated data types (`ENUM`)
- Arrays of composite types
- Universally Unique Identifier (`UUID`) data type
- Add control over whether `NULLs` sort first or last
- Updatable cursors
- Server configuration parameters can now be set on a per-function basis

- User-defined types can now have type modifiers
- Automatically re-plan cached queries when table definitions change or statistics are updated
- Numerous improvements in logging and statistics collection
- Support Security Service Provider Interface (SSPI) for authentication on Windows
- Support multiple concurrent autovacuum processes, and other autovacuum improvements
- Allow the whole PostgreSQL distribution to be compiled with Microsoft Visual C++

Major performance improvements are listed below. Most of these enhancements are automatic and do not require user changes or tuning:

- Asynchronous commit delays writes to WAL during transaction commit
- Checkpoint writes can be spread over a longer time period to smooth the I/O spike during each checkpoint
- Heap-Only Tuples (HOT) accelerate space reuse for most `UPDATES` and `DELETES`
- Just-in-time background writer strategy improves disk write efficiency
- Using non-persistent transaction IDs for read-only transactions reduces overhead and `VACUUM` requirements
- Per-field and per-row storage overhead has been reduced
- Large sequential scans no longer force out frequently used cached pages
- Concurrent large sequential scans can now share disk reads
- `ORDER BY ... LIMIT` can be done without sorting

The above items are explained in more detail in the sections below.

## E.2.2. Migration to Version 8.3

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

Observe the following incompatibilities:

### E.2.2.1. General

- Non-character data types are no longer automatically cast to `TEXT` (Peter, Tom)

Previously, if a non-character value was supplied to an operator or function that requires `text` input, it was automatically cast to `text`, for most (though not all) built-in data types. This no longer happens: an explicit cast to `text` is now required for all non-character-string types. For example, these expressions formerly worked:

```
substr(current_date, 1, 4)
23 LIKE '2%'
```

but will now draw “function does not exist” and “operator does not exist” errors respectively. Use an explicit cast instead:

```
substr(current_date::text, 1, 4)
```

```
23::text LIKE '2%'
```

(Of course, you can use the more verbose `CAST()` syntax too.) The reason for the change is that these automatic casts too often caused surprising behavior. An example is that in previous releases, this expression was accepted but did not do what was expected:

```
current_date < 2017-11-17
```

This is actually comparing a date to an integer, which should be (and now is) rejected — but in the presence of automatic casts both sides were cast to `text` and a textual comparison was done, because the `text < text` operator was able to match the expression when no other `<` operator could.

Types `char(n)` and `varchar(n)` still cast to `text` automatically. Also, automatic casting to `text` still works for inputs to the concatenation (`||`) operator, so long as at least one input is a character-string type.

- Full text search features from `contrib/tsearch2` have been moved into the core server, with some minor syntax changes

`contrib/tsearch2` now contains a compatibility interface.

- `ARRAY(SELECT ...)`, where the `SELECT` returns no rows, now returns an empty array, rather than `NULL` (Tom)
- The array type name for a base data type is no longer always the base type's name with an underscore prefix

The old naming convention is still honored when possible, but application code should no longer depend on it. Instead use the new `pg_type.typarray` column to identify the array data type associated with a given type.

- `ORDER BY ... USING operator` must now use a less-than or greater-than *operator* that is defined in a btree operator class

This restriction was added to prevent inconsistent results.

- `SET LOCAL` changes now persist until the end of the outermost transaction, unless rolled back (Tom)

Previously `SET LOCAL`'s effects were lost after subtransaction commit (`RELEASE SAVEPOINT` or exit from a PL/pgSQL exception block).

- Commands rejected in transaction blocks are now also rejected in multiple-statement query strings (Tom)

For example, `"BEGIN; DROP DATABASE; COMMIT"` will now be rejected even if submitted as a single query message.

- `ROLLBACK` outside a transaction block now issues `NOTICE` instead of `WARNING` (Bruce)
- Prevent `NOTIFY/LISTEN/UNLISTEN` from accepting schema-qualified names (Bruce)

Formerly, these commands accepted `schema.relation` but ignored the schema part, which was confusing.

- `ALTER SEQUENCE` no longer affects the sequence's `currval()` state (Tom)
- Foreign keys now must match indexable conditions for cross-data-type references (Tom)

This improves semantic consistency and helps avoid performance problems.

- Restrict object size functions to users who have reasonable permissions to view such information (Tom)

For example, `pg_database_size()` now requires `CONNECT` permission, which is granted to everyone by default. `pg_tablespace_size()` requires `CREATE` permission in the tablespace, or is allowed if the tablespace is the default tablespace for the database.

- Remove the undocumented `!=` (not in) operator (Tom)

`NOT IN (SELECT ...)` is the proper way to perform this operation.

- Internal hashing functions are now more uniformly-distributed (Tom)

If application code was computing and storing hash values using internal PostgreSQL hashing functions, the hash values must be regenerated.

- C-code conventions for handling variable-length data values have changed (Greg Stark, Tom)

The new `SET_VARSIZE()` macro *must* be used to set the length of generated `varlena` values. Also, it might be necessary to expand (“de-TOAST”) input values in more cases.

- Continuous archiving no longer reports each successful archive operation to the server logs unless `DEBUG` level is used (Simon)

### E.2.2.2. Configuration Parameters

- Numerous changes in administrative server parameters

`bgwriter_lru_percent`, `bgwriter_all_percent`, `bgwriter_all_maxpages`, `stats_start_collector`, and `stats_reset_on_server_start` are removed. `redirect_stderr` is renamed to `logging_collector`. `stats_command_string` is renamed to `track_activities`. `stats_block_level` and `stats_row_level` are merged into `track_counts`. A new boolean configuration parameter, `archive_mode`, controls archiving. Autovacuum’s default settings have changed.

- Remove `stats_start_collector` parameter (Tom)

We now always start the collector process, unless UDP socket creation fails.

- Remove `stats_reset_on_server_start` parameter (Tom)

This was removed because `pg_stat_reset()` can be used for this purpose.

- Commenting out a parameter in `postgresql.conf` now causes it to revert to its default value (Joachim Wieland)

Previously, commenting out an entry left the parameter’s value unchanged until the next server restart.

### E.2.2.3. Character Encodings

- Add more checks for invalidly-encoded data (Andrew)

This change plugs some holes that existed in literal backslash escape string processing and `COPY` escape processing. Now the de-escaped string is rechecked to see if the result created an invalid multi-byte character.

- Disallow database encodings that are inconsistent with the server’s locale setting (Tom)

On most platforms, `C` locale is the only locale that will work with any database encoding. Other locale settings imply a specific encoding and will misbehave if the database encoding is something different. (Typical symptoms include bogus textual sort order and wrong results from `upper()` or `lower()`.) The server now rejects attempts to create databases that have an incompatible encoding.

- Ensure that `chr()` cannot create invalidly-encoded values (Andrew)

In UTF8-encoded databases the argument of `chr()` is now treated as a Unicode code point. In other multi-byte encodings `chr()`'s argument must designate a 7-bit ASCII character. Zero is no longer accepted. `ascii()` has been adjusted to match.

- Adjust `convert()` behavior to ensure encoding validity (Andrew)

The two argument form of `convert()` has been removed. The three argument form now takes a `bytea` first argument and returns a `bytea`. To cover the loss of functionality, three new functions have been added:

- `convert_from(bytea, name)` returns `text` — converts the first argument from the named encoding to the database encoding
- `convert_to(text, name)` returns `bytea` — converts the first argument from the database encoding to the named encoding
- `length(bytea, name)` returns `integer` — gives the length of the first argument in characters in the named encoding
- Remove `convert(argument USING conversion_name)` (Andrew)  
Its behavior did not match the SQL standard.
- Make JOHAB encoding client-only (Tatsuo)  
JOHAB is not safe as a server-side encoding.

## E.2.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 8.3 and the previous major release.

### E.2.3.1. Performance

- Asynchronous commit delays writes to WAL during transaction commit (Simon)

This feature dramatically increases performance for short data-modifying transactions. The disadvantage is that because disk writes are delayed, if the database or operating system crashes before data is written to the disk, committed data will be lost. This feature is useful for applications that can accept some data loss. Unlike turning off `fsync`, using asynchronous commit does not put database consistency at risk; the worst case is that after a crash the last few reportedly-committed transactions might not be committed after all. This feature is enabled by turning off `synchronous_commit` (which can be done per-session or per-transaction, if some transactions are critical and others are not).

`wal_writer_delay` can be adjusted to control the maximum delay before transactions actually reach disk.

- Checkpoint writes can be spread over a longer time period to smooth the I/O spike during each checkpoint (Itagaki Takahiro and Heikki Linnakangas)

Previously all modified buffers were forced to disk as quickly as possible during a checkpoint, causing an I/O spike that decreased server performance. This new approach spreads out disk writes during checkpoints, reducing peak I/O usage. (User-requested and shutdown checkpoints are still written as quickly as possible.)

- Heap-Only Tuples (HOT) accelerate space reuse for most `UPDATES` and `DELETES` (Pavan Deolasee, with ideas from many others)

`UPDATES` and `DELETES` leave dead tuples behind, as do failed `INSERTs`. Previously only `VACUUM` could reclaim space taken by dead tuples. With HOT dead tuple space can be automatically reclaimed at the time of `INSERT` or `UPDATE` if no changes are made to indexed columns. This allows for more consistent performance. Also, HOT avoids adding duplicate index entries.

- Just-in-time background writer strategy improves disk write efficiency (Greg Smith, Itagaki Takahiro)

This greatly reduces the need for manual tuning of the background writer.

- Per-field and per-row storage overhead have been reduced (Greg Stark, Heikki Linnakangas)

Variable-length data types with data values less than 128 bytes long will see a storage decrease of 3 to 6 bytes. For example, two adjacent `char(1)` fields now use 4 bytes instead of 16. Row headers are also 4 bytes shorter than before.

- Using non-persistent transaction IDs for read-only transactions reduces overhead and `VACUUM` requirements (Florian Pflug)

Non-persistent transaction IDs do not increment the global transaction counter. Therefore, they reduce the load on `pg_clog` and increase the time between forced vacuums to prevent transaction ID wraparound. Other performance improvements were also made that should improve concurrency.

- Avoid incrementing the command counter after a read-only command (Tom)

There was formerly a hard limit of  $2^{32}$  (4 billion) commands per transaction. Now only commands that actually changed the database count, so while this limit still exists, it should be significantly less annoying.

- Create a dedicated WAL writer process to off-load work from backends (Simon)

- Skip unnecessary WAL writes for `CLUSTER` and `COPY` (Simon)

Unless WAL archiving is enabled, the system now avoids WAL writes for `CLUSTER` and just `fsync()`s the table at the end of the command. It also does the same for `COPY` if the table was created in the same transaction.

- Large sequential scans no longer force out frequently used cached pages (Simon, Heikki, Tom)

- Concurrent large sequential scans can now share disk reads (Jeff Davis)

This is accomplished by starting the new sequential scan in the middle of the table (where another sequential scan is already in-progress) and wrapping around to the beginning to finish. This can affect the order of returned rows in a query that does not specify `ORDER BY`. The `synchronize_seqscans` configuration parameter can be used to disable this if necessary.

- `ORDER BY ... LIMIT` can be done without sorting (Greg Stark)

This is done by sequentially scanning the table and tracking just the “top N” candidate rows, rather than performing a full sort of the entire table. This is useful when there is no matching index and the `LIMIT` is not large.

- Put a rate limit on messages sent to the statistics collector by backends (Tom)

This reduces overhead for short transactions, but might sometimes increase the delay before statistics are tallied.

- Improve hash join performance for cases with many NULLs (Tom)
- Speed up operator lookup for cases with non-exact datatype matches (Tom)

### E.2.3.2. Server

- Autovacuum is now enabled by default (Alvaro)

Several changes were made to eliminate disadvantages of having autovacuum enabled, thereby justifying the change in default. Several other autovacuum parameter defaults were also modified.

- Support multiple concurrent autovacuum processes (Alvaro, Itagaki Takahiro)

This allows multiple vacuums to run concurrently. This prevents vacuuming of a large table from delaying vacuuming of smaller tables.

- Automatically re-plan cached queries when table definitions change or statistics are updated (Tom)

Previously PL/PgSQL functions that referenced temporary tables would fail if the temporary table was dropped and recreated between function invocations, unless `EXECUTE` was used. This improvement fixes that problem and many related issues.

- Add a `temp_tablespaces` parameter to control the tablespaces for temporary tables and files (Jaime Casanova, Albert Cervera, Bernd Helmle)

This parameter defines a list of tablespaces to be used. This enables spreading the I/O load across multiple tablespaces. A random tablespace is chosen each time a temporary object is created. Temporary files are no longer stored in per-database `pgsql_tmp/` directories but in per-tablespace directories.

- Place temporary tables' TOAST tables in special schemas named `pg_toast_temp_nnn` (Tom)

This allows low-level code to recognize these tables as temporary, which enables various optimizations such as not WAL-logging changes and using local rather than shared buffers for access. This also fixes a bug wherein backends unexpectedly held open file references to temporary TOAST tables.

- Fix problem that a constant flow of new connection requests could indefinitely delay the postmaster from completing a shutdown or a crash restart (Tom)
- Guard against a very-low-probability data loss scenario by preventing re-use of a deleted table's `relfilenode` until after the next checkpoint (Heikki)
- Fix `CREATE CONSTRAINT TRIGGER` to convert old-style foreign key trigger definitions into regular foreign key constraints (Tom)

This will ease porting of foreign key constraints carried forward from pre-7.3 databases, if they were never converted using `contrib/adddepend`.

- Fix `DEFAULT NULL` to override inherited defaults (Tom)

`DEFAULT NULL` was formerly considered a noise phrase, but it should (and now does) override non-null defaults that would otherwise be inherited from a parent table or domain.

- Add new encodings `EUC_JIS_2004` and `SHIFT_JIS_2004` (Tatsuo)

These new encodings can be converted to and from UTF-8.

- Change server startup log message from “database system is ready” to “database system is ready to accept connections”, and adjust its timing

The message now appears only when the postmaster is really ready to accept connections.

### E.2.3.3. Monitoring

- Add `log_autovacuum_min_duration` parameter to support configurable logging of autovacuum activity (Simon, Alvaro)
- Add `log_lock_waits` parameter to log lock waiting (Simon)
- Add `log_temp_files` parameter to log temporary file usage (Bill Moran)
- Add `log_checkpoints` parameter to improve logging of checkpoints (Greg Smith, Heikki)
- `log_line_prefix` now supports `%s` and `%c` escapes in all processes (Andrew)

Previously these escapes worked only for user sessions, not for background database processes.

- Add `log_restartpoints` to control logging of point-in-time recovery restart points (Simon)
- Last transaction end time is now logged at end of recovery and at each logged restart point (Simon)
- Autovacuum now reports its activity start time in `pg_stat_activity` (Tom)
- Allow server log output in comma-separated value (CSV) format (Arul Shaji, Greg Smith, Andrew Dunstan)

CSV-format log files can easily be loaded into a database table for subsequent analysis.

- Use PostgreSQL-supplied timezone support for formatting timestamps displayed in the server log (Tom)

This avoids Windows-specific problems with localized time zone names that are in the wrong encoding. There is a new `log_timezone` parameter that controls the timezone used in log messages, independently of the client-visible `timezone` parameter.

- New system view `pg_stat_bgwriter` displays statistics about background writer activity (Magnus)
- Add new columns for database-wide tuple statistics to `pg_stat_database` (Magnus)
- Add an `xact_start` (transaction start time) column to `pg_stat_activity` (Neil)

This makes it easier to identify long-running transactions.

- Add `n_live_tuples` and `n_dead_tuples` columns to `pg_stat_all_tables` and related views (Glen Parker)
- Merge `stats_block_level` and `stats_row_level` parameters into a single parameter `track_counts`, which controls all messages sent to the statistics collector process (Tom)

- Rename `stats_command_string` parameter to `track_activities` (Tom)
- Fix statistical counting of live and dead tuples to recognize that committed and aborted transactions have different effects (Tom)

#### E.2.3.4. Authentication

- Support Security Service Provider Interface (SSPI) for authentication on Windows (Magnus)
- Support GSSAPI authentication (Henry Hotz, Magnus)

This should be preferred to native Kerberos authentication because GSSAPI is an industry standard.

- Support a global SSL configuration file (Victor Wagner)
- Add `ssl_ciphers` parameter to control accepted SSL ciphers (Victor Wagner)
- Add a Kerberos realm parameter, `krb_realm` (Magnus)

#### E.2.3.5. Write-Ahead Log (WAL) and Continuous Archiving

- Change the timestamps recorded in transaction WAL records from `time_t` to `TimestampTz` representation (Tom)

This provides sub-second resolution in WAL, which can be useful for point-in-time recovery.

- Reduce WAL disk space needed by warm standby servers (Simon)

This change allows a warm standby server to pass the name of the earliest still-needed WAL file to the recovery script, allowing automatic removal of no-longer-needed WAL files. This is done using `%r` in the `restore_command` parameter of `recovery.conf`.

- New boolean configuration parameter, `archive_mode`, controls archiving (Simon)

Previously setting `archive_command` to an empty string turned off archiving. Now `archive_mode` turns archiving on and off, independently of `archive_command`. This is useful for stopping archiving temporarily.

#### E.2.3.6. Queries

- Full text search is integrated into the core database system (Teodor, Oleg)

Text search has been improved, moved into the core code, and is now installed by default. `contrib/tsearch2` now contains a compatibility interface.

- Add control over whether `NULL`s sort first or last (Teodor, Tom)

The syntax is `ORDER BY ... NULLS FIRST/LAST`.

- Allow per-column ascending/descending (`ASC/DESC`) ordering options for indexes (Teodor, Tom)

Previously a query using `ORDER BY` with mixed `ASC/DESC` specifiers could not fully use an index. Now an index can be fully used in such cases if the index was created with matching `ASC/DESC` specifications. `NULL` sort order within an index can be controlled, too.

- Allow `col IS NULL` to use an index (Teodor)
- Updatable cursors (Arul Shaji, Tom)

This eliminates the need to reference a primary key to `UPDATE` or `DELETE` rows returned by a cursor. The syntax is `UPDATE/DELETE WHERE CURRENT OF`.

- Allow `FOR UPDATE` in cursors (Arul Shaji, Tom)
- Create a general mechanism that supports casts to and from the standard string types (`TEXT`, `VARCHAR`, `CHAR`) for *every* datatype, by invoking the datatype's I/O functions (Tom)

Previously, such casts were available only for types that had specialized function(s) for the purpose. These new casts are assignment-only in the to-string direction, explicit-only in the other direction, and therefore should create no surprising behavior.

- Allow `UNION` and related constructs to return a domain type, when all inputs are of that domain type (Tom)

Formerly, the output would be considered to be of the domain's base type.

- Allow limited hashing when using two different data types (Tom)

This allows hash joins, hash indexes, hashed subplans, and hash aggregation to be used in situations involving cross-data-type comparisons, if the data types have compatible hash functions. Currently, cross-data-type hashing support exists for `smallint/integer/bigint`, and for `float4/float8`.

- Improve optimizer logic for detecting when variables are equal in a `WHERE` clause (Tom)

This allows mergejoins to work with descending sort orders, and improves recognition of redundant sort columns.

- Improve performance when planning large inheritance trees in cases where most tables are excluded by constraints (Tom)

### E.2.3.7. Object Manipulation

- Arrays of composite types (David Fetter, Andrew, Tom)

In addition to arrays of explicitly-declared composite types, arrays of the rowtypes of regular tables and views are now supported, except for rowtypes of system catalogs, sequences, and TOAST tables.

- Server configuration parameters can now be set on a per-function basis (Tom)

For example, functions can now set their own `search_path` to prevent unexpected behavior if a different `search_path` exists at run-time. Security definer functions should set `search_path` to avoid security loopholes.

- `CREATE/ALTER FUNCTION` now supports `COST` and `ROWS` options (Tom)

`COST` allows specification of the cost of a function call. `ROWS` allows specification of the average number of rows returned by a set-returning function. These values are used by the optimizer in choosing the best plan.

- Implement `CREATE TABLE LIKE ... INCLUDING INDEXES` (Trevor Hardcastle, Nikhil Sontakke, Neil)
- Allow `CREATE INDEX CONCURRENTLY` to ignore transactions in other databases (Simon)
- Add `ALTER VIEW ... RENAME TO` and `ALTER SEQUENCE ... RENAME TO` (David Fetter, Neil)  
Previously this could only be done via `ALTER TABLE ... RENAME TO`.
- Make `CREATE/DROP/RENAME DATABASE` wait briefly for conflicting backends to exit before failing (Tom)  
This increases the likelihood that these commands will succeed.
- Allow triggers and rules to be deactivated in groups using a configuration parameter, for replication purposes (Jan)  
This allows replication systems to disable triggers and rewrite rules as a group without modifying the system catalogs directly. The behavior is controlled by `ALTER TABLE` and a new parameter `session_replication_role`.
- User-defined types can now have type modifiers (Teodor, Tom)  
This allows a user-defined type to take a modifier, like `ssnum(7)`. Previously only built-in data types could have modifiers.

### E.2.3.8. Utility Commands

- Non-superuser database owners now are able to add trusted procedural languages to their databases by default (Jeremy Drake)  
While this is reasonably safe, some administrators might wish to revoke the privilege. It is controlled by `pg_pltemplate.tmpldbacreate`.
- Allow a session's current parameter setting to be used as the default for future sessions (Tom)  
This is done with `SET ... FROM CURRENT` in `CREATE/ALTER FUNCTION`, `ALTER DATABASE`, or `ALTER ROLE`.
- Implement new commands `DISCARD ALL`, `DISCARD PLANS`, `DISCARD TEMPORARY`, `CLOSE ALL`, and `DEALLOCATE ALL` (Marko Kreen, Neil)  
These commands simplify resetting a database session to its initial state, and are particularly useful for connection-pooling software.
- Make `CLUSTER` MVCC-safe (Heikki Linnakangas)  
Formerly, `CLUSTER` would discard all tuples that were committed dead, even if there were still transactions that should be able to see them under MVCC visibility rules.
- Add new `CLUSTER` syntax: `CLUSTER table USING index` (Holger Schurig)  
The old `CLUSTER` syntax is still supported, but the new form is considered more logical.
- Fix `EXPLAIN` so it can show complex plans more accurately (Tom)  
References to subplan outputs are now always shown correctly, instead of using `?columnN?` for complicated cases.

- Limit the amount of information reported when a user is dropped (Alvaro)

Previously, dropping (or attempting to drop) a user who owned many objects could result in large `NOTICE` or `ERROR` messages listing all these objects; this caused problems for some client applications. The length of the message is now limited, although a full list is still sent to the server log.

### E.2.3.9. Data Types

- Support for the SQL/XML standard, including new operators and an XML data type (Nikolay Samokhvalov, Pavel Stehule, Peter)
- Enumerated data types (`ENUM`) (Tom Dunstan)

This feature provides convenient support for fields that have a small, fixed set of allowed values. An example of creating an `ENUM` type is `CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy')`.

- Universally Unique Identifier (`UUID`) data type (Gevik Babakhani, Neil)

This closely matches RFC 4122.

- Widen the `MONEY` data type to 64 bits (D'Arcy Cain)

This greatly increases the range of supported `MONEY` values.

- Fix `float4/float8` to handle Infinity and NAN (Not A Number) consistently (Bruce)

The code formerly was not consistent about distinguishing Infinity from overflow conditions.

- Allow leading and trailing whitespace during input of `boolean` values (Neil)
- Prevent `COPY` from using digits and lowercase letters as delimiters (Tom)

### E.2.3.10. Functions

- Add new regular expression functions `regexp_matches()`, `regexp_split_to_array()`, and `regexp_split_to_table()` (Jeremy Drake, Neil)

These functions provide extraction of regular expression subexpressions and allow splitting a string using a POSIX regular expression.

- Add `lo_truncate()` for large object truncation (Kris Jurka)
- Implement `width_bucket()` for the `float8` data type (Neil)
- Add `pg_stat_clear_snapshot()` to discard statistics snapshots collected during the current transaction (Tom)

The first request for statistics in a transaction takes a statistics snapshot that does not change during the transaction. This function allows the snapshot to be discarded and a new snapshot loaded during the next statistics query. This is particularly useful for PL/PgSQL functions, which are confined to a single transaction.

- Add `isodow` option to `EXTRACT()` and `date_part()` (Bruce)

This returns the day of the week, with Sunday as seven. (`dow` returns Sunday as zero.)

- Add `ID` (ISO day of week) and `IDDD` (ISO day of year) format codes for `to_char()`, `to_date()`, and `to_timestamp()` (Brendan Jurd)
- Make `to_timestamp()` and `to_date()` assume `TM` (trim) option for potentially variable-width fields (Bruce)

This matches Oracle's behavior.

- Fix off-by-one conversion error in `to_date()/to_timestamp()` `D` (non-ISO day of week) fields (Bruce)
- Make `setseed()` return void, rather than a useless integer value (Neil)
- Add a hash function for `NUMERIC` (Neil)

This allows hash indexes and hash-based plans to be used with `NUMERIC` columns.

- Improve efficiency of `LIKE/ILIKE`, especially for multi-byte character sets like UTF-8 (Andrew, Itagaki Takahiro)
- Make `currtd()` functions require `SELECT` privileges on the target table (Tom)
- Add several `txid_*` functions to query active transaction IDs (Jan)

This is useful for various replication solutions.

### E.2.3.11. PL/PgSQL Server-Side Language

- Add scrollable cursor support, including directional control in `FETCH` (Pavel Stehule)
- Allow `IN` as an alternative to `FROM` in PL/PgSQL's `FETCH` statement, for consistency with the backend's `FETCH` command (Pavel Stehule)
- Add `MOVE` to PL/PgSQL (Magnus, Pavel Stehule, Neil)
- Implement `RETURN QUERY` (Pavel Stehule, Neil)

This adds convenient syntax for PL/PgSQL set-returning functions that want to return the result of a query. `RETURN QUERY` is easier and more efficient than a loop around `RETURN NEXT`.

- Allow function parameter names to be qualified with the function's name (Tom)

For example, `myfunc.myvar`. This is particularly useful for specifying variables in a query where the variable name might match a column name.

- Make qualification of variables with block labels work properly (Tom)

Formerly, outer-level block labels could unexpectedly interfere with recognition of inner-level record or row references.

- Tighten requirements for `FOR` loop `STEP` values (Tom)
- Prevent non-positive `STEP` values, and handle loop overflows.
- Improve accuracy when reporting syntax error locations (Tom)

### E.2.3.12. Other Server-Side Languages

- Allow type-name arguments to PL/Perl `spi_prepare()` to be data type aliases in addition to names found in `pg_type` (Andrew)
- Allow type-name arguments to PL/Python `plpy.prepare()` to be data type aliases in addition to names found in `pg_type` (Andrew)
- Allow type-name arguments to PL/Tcl `spi_prepare` to be data type aliases in addition to names found in `pg_type` (Andrew)
- Enable PL/PythonU to compile on Python 2.5 (Marko Kreen)
- Support a true PL/Python boolean type in compatible Python versions (Python 2.3 and later) (Marko Kreen)
- Fix PL/Tcl problems with thread-enabled `libtcl` spawning multiple threads within the backend (Steve Marshall, Paul Bayer, Doug Knight)  
This caused all sorts of unpleasantness.

### E.2.3.13. `psql`

- List disabled triggers separately in `\d` output (Brendan Jurd)
- In `\d` patterns, always match `$` literally (Tom)
- Show aggregate return types in `\da` output (Greg Sabino Mullane)
- Add the function's volatility status to the output of `\df+` (Neil)
- Add `\prompt` capability (Chad Wagner)
- Allow `\pset`, `\t`, and `\x` to specify `on` or `off`, rather than just toggling (Chad Wagner)
- Add `\sleep` capability (Jan)
- Enable `\timing` output for `\copy` (Andrew)
- Improve `\timing` resolution on Windows (Itagaki Takahiro)
- Flush `\o` output after each backslash command (Tom)
- Correctly detect and report errors while reading a `-f` input file (Peter)
- Remove `-u` option (this option has long been deprecated) (Tom)

### E.2.3.14. `pg_dump`

- Add `--tablespaces-only` and `--roles-only` options to `pg_dumpall` (Dave Page)
- Add an output file option to `pg_dumpall` (Dave Page)

This is primarily useful on Windows, where output redirection of child `pg_dump` processes does not work.

- Allow `pg_dumpall` to accept an initial-connection database name rather than the default `template1` (Dave Page)
- In `-n` and `-t` switches, always match `$` literally (Tom)
- Improve performance when a database has thousands of objects (Tom)
- Remove `-u` option (this option has long been deprecated) (Tom)

### E.2.3.15. Other Client Applications

- In `initdb`, allow the location of the `pg_xlog` directory to be specified (Euler Taveira de Oliveira)
- Enable server core dump generation in `pg_regress` on supported operating systems (Andrew)
- Add a `-t` (timeout) parameter to `pg_ctl` (Bruce)

This controls how long `pg_ctl` will wait when waiting for server startup or shutdown. Formerly the timeout was hard-wired as 60 seconds.

- Add a `pg_ctl` option to control generation of server core dumps (Andrew)
- Allow Control-C to cancel `clusterdb`, `reindexdb`, and `vacuumdb` (Itagaki Takahiro, Magnus)
- Suppress command tag output for `createdb`, `createuser`, `dropdb`, and `dropuser` (Peter)

The `--quiet` option is ignored and will be removed in 8.4. Progress messages when acting on all databases now go to `stdout` instead of `stderr` because they are not actually errors.

### E.2.3.16. libpq

- Interpret the `dbName` parameter of `PQsetdbLogin()` as a `conninfo` string if it contains an equals sign (Andrew)

This allows use of `conninfo` strings in client programs that still use `PQsetdbLogin()`.

- Support a global SSL configuration file (Victor Wagner)
- Add environment variable `PGSSLKEY` to control SSL hardware keys (Victor Wagner)
- Add `lo_truncate()` for large object truncation (Kris Jurka)
- Add `PQconnectionNeedsPassword()` that returns true if the server required a password but none was supplied (Joe Conway, Tom)

If this returns true after a failed connection attempt, a client application should prompt the user for a password. In the past applications have had to check for a specific error message string to decide whether a password is needed; that approach is now deprecated.

- Add `PQconnectionUsedPassword()` that returns true if the supplied password was actually used (Joe Conway, Tom)

This is useful in some security contexts where it is important to know whether a user-supplied password is actually valid.

**E.2.3.17. ecpg**

- Use V3 frontend/backend protocol (Michael)  
This adds support for server-side prepared statements.
- Use native threads, instead of pthreads, on Windows (Magnus)
- Improve thread-safety of ecpglib (Itagaki Takahiro)
- Make the ecpg libraries export only necessary API symbols (Michael)

**E.2.3.18. Windows Port**

- Allow the whole PostgreSQL distribution to be compiled with Microsoft Visual C++ (Magnus and others)  
This allows Windows-based developers to use familiar development and debugging tools. Windows executables made with Visual C++ might also have better stability and performance than those made with other tool sets. The client-only Visual C++ build scripts have been removed.
- Drastically reduce postmaster's memory usage when it has many child processes (Magnus)
- Allow regression tests to be started by an administrative user (Magnus)
- Add native shared memory implementation (Magnus)

**E.2.3.19. Server Programming Interface (SPI)**

- Add cursor-related functionality in SPI (Pavel Stehule)  
Allow access to the cursor-related planning options, and add `FETCH/MOVE` routines.
- Allow execution of cursor commands through `SPI_execute` (Tom)  
The macro `SPI_ERROR_CURSOR` still exists but will never be returned.
- SPI plan pointers are now declared as `SPIPlanPtr` instead of `void *` (Tom)  
This does not break application code, but switching is recommended to help catch simple programming mistakes.

**E.2.3.20. Build Options**

- Add configure option `--enable-profiling` to enable code profiling (works only with gcc) (Korry Douglas and Nikhil Sontakke)
- Add configure option `--with-system-tzdata` to use the operating system's time zone database (Peter)
- Fix PGXS so extensions can be built against PostgreSQL installations whose `pg_config` program does not appear first in the `PATH` (Tom)

- Support `gmake draft` when building the SGML documentation (Bruce)

Unless `draft` is used, the documentation build will now be repeated if necessary to ensure the index is up-to-date.

### E.2.3.21. Source Code

- Rename macro `DLLIMPORT` to `PGDLLIMPORT` to avoid conflicting with third party includes (like `Tcl`) that define `DLLIMPORT` (Magnus)
- Create “operator families” to improve planning of queries involving cross-data-type comparisons (Tom)
- Update `GIN extractQuery()` API to allow signalling that nothing can satisfy the query (Teodor)
- Move `NAMEDATALEN` definition from `postgres_ext.h` to `pg_config_manual.h` (Peter)
- Provide `strncpy()` and `strlcat()` on all platforms, and replace error-prone uses of `strncpy()`, `strncat()`, etc (Peter)
- Create hooks to let an external plugin monitor (or even replace) the planner and create plans for hypothetical situations (Gurjeet Singh, Tom)
- Create a function variable `join_search_hook` to let plugins override the join search order portion of the planner (Julius Stroffek)
- Add `tas()` support for Renesas’ M32R processor (Kazuhiro Inaoka)
- `quote_identifier()` and `pg_dump` no longer quote keywords that are unreserved according to the grammar (Tom)
- Change the on-disk representation of the `NUMERIC` data type so that the `sign_dscale` word comes before the weight (Tom)
- Use `SYSV` semaphores rather than `POSIX` on Darwin  $\geq 6.0$ , i.e., OS X 10.2 and up (Chris Marcellino)
- Add acronym and NFS documentation sections (Bruce)
- “Postgres” is now documented as an accepted alias for “PostgreSQL” (Peter)
- Add documentation about preventing database server spoofing when the server is down (Bruce)

### E.2.3.22. Contrib

- Move `contrib README` content into the main PostgreSQL documentation (Albert Cervera i Areny)
- Add `contrib/pageinspect` module for low-level page inspection (Simon, Heikki)
- Add `contrib/pg_standby` module for controlling warm standby operation (Simon)
- Add `contrib/uuid-ossdp` module for generating `UUID` values using the `OSSP UUID` library (Peter)  
Use `configure --with-ossdp-uuid` to activate. This takes advantage of the new `UUID` builtin type.
- Add `contrib/dict_int`, `contrib/dict_xsyn`, and `contrib/test_parser` modules to provide sample add-on text search dictionary templates and parsers (Sergey Karpov)
- Allow `contrib/pgbench` to set the `fillfactor` (Pavan Deolasee)

- Add timestamps to `contrib/pgbench -l` (Greg Smith)
  - Add usage count statistics to `contrib/pgbuffercache` (Greg Smith)
  - Add GIN support for `contrib/hstore` (Teodor)
  - Add GIN support for `contrib/pg_trgm` (Guillaume Smet, Teodor)
  - Update OS/X startup scripts in `contrib/start-scripts` (Mark Cotner, David Fetter)
  - Restrict `pgrowlocks()` and `dblink_get_pkey()` to users who have `SELECT` privilege on the target table (Tom)
  - Restrict `contrib/pgstattuple` functions to superusers (Tom)
  - `contrib/xml2` is deprecated and planned for removal in 8.4 (Peter)
- The new XML support in core PostgreSQL supersedes this module.

## E.3. Release 8.2.7

**Release date:** 2008-03-17

This release contains a variety of fixes from 8.2.6.

### E.3.1. Migration to Version 8.2.7

A dump/restore is not required for those running 8.2.X. However, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the Windows locale issue described below.

### E.3.2. Changes

- Fix character string comparison for Windows locales that consider different character combinations as equal (Tom)

This fix applies only on Windows and only when using UTF-8 database encoding. The same fix was made for all other cases over two years ago, but Windows with UTF-8 uses a separate code path that was not updated. If you are using a locale that considers some non-identical strings as equal, you may need to `REINDEX` to fix existing indexes on textual columns.

- Repair potential deadlock between concurrent `VACUUM FULL` operations on different system catalogs (Tom)
- Fix longstanding `LISTEN/NOTIFY` race condition (Tom)

In rare cases a session that had just executed a `LISTEN` might not get a notification, even though one would be expected because the concurrent transaction executing `NOTIFY` was observed to commit later.

A side effect of the fix is that a transaction that has executed a not-yet-committed `LISTEN` command will not see any row in `pg_listener` for the `LISTEN`, should it choose to look; formerly it would have. This behavior was never documented one way or the other, but it is possible that some applications depend on the old behavior.

- Disallow `LISTEN` and `UNLISTEN` within a prepared transaction (Tom)

This was formerly allowed but trying to do it had various unpleasant consequences, notably that the originating backend could not exit as long as an `UNLISTEN` remained uncommitted.

- Disallow dropping a temporary table within a prepared transaction (Heikki)

This was correctly disallowed by 8.1, but the check was inadvertently broken in 8.2.

- Fix rare crash when an error occurs during a query using a hash index (Heikki)
- Fix memory leaks in certain usages of set-returning functions (Neil)
- Fix input of datetime values for February 29 in years BC (Tom)

The former coding was mistaken about which years were leap years.

- Fix “unrecognized node type” error in some variants of `ALTER OWNER` (Tom)
- Ensure `pg_stat_activity.waiting` flag is cleared when a lock wait is aborted (Tom)
- Fix handling of process permissions on Windows Vista (Dave, Magnus)

In particular, this fix allows starting the server as the Administrator user.

- Update time zone data files to tzdata release 2008a (in particular, recent Chile changes); adjust timezone abbreviation `VET` (Venezuela) to mean UTC-4:30, not UTC-4:00 (Tom)
- Fix `pg_ctl` to correctly extract the postmaster’s port number from command-line options (Itagaki Takahiro, Tom)

Previously, `pg_ctl start -w` could try to contact the postmaster on the wrong port, leading to bogus reports of startup failure.

- Use `-fwrapv` to defend against possible misoptimization in recent gcc versions (Tom)

This is known to be necessary when building PostgreSQL with gcc 4.3 or later.

- Correctly enforce `statement_timeout` values longer than `INT_MAX` microseconds (about 35 minutes) (Tom)

This bug affects only builds with `--enable-integer-datetimes`.

- Fix “unexpected `PARAM_SUBLINK ID`” planner error when constant-folding simplifies a sub-select (Tom)

- Fix logical errors in constraint-exclusion handling of `IS NULL` and `NOT` expressions (Tom)

The planner would sometimes exclude partitions that should not have been excluded because of the possibility of `NULL` results.

- Fix another cause of “failed to build any N-way joins” planner errors (Tom)

This could happen in cases where a clauseless join needed to be forced before a join clause could be exploited.

- Fix incorrect constant propagation in outer-join planning (Tom)

The planner could sometimes incorrectly conclude that a variable could be constrained to be equal to a constant, leading to wrong query results.

- Fix display of constant expressions in `ORDER BY` and `GROUP BY` (Tom)

An explicitly casted constant would be shown incorrectly. This could for example lead to corruption of a view definition during dump and reload.

- Fix libpq to handle NOTICE messages correctly during COPY OUT (Tom)

This failure has only been observed to occur when a user-defined datatype's output routine issues a NOTICE, but there is no guarantee it couldn't happen due to other causes.

## E.4. Release 8.2.6

**Release date:** 2008-01-07

This release contains a variety of fixes from 8.2.5, including fixes for significant security issues.

### E.4.1. Migration to Version 8.2.6

A dump/restore is not required for those running 8.2.X.

### E.4.2. Changes

- Prevent functions in indexes from executing with the privileges of the user running `VACUUM`, `ANALYZE`, etc (Tom)

Functions used in index expressions and partial-index predicates are evaluated whenever a new table entry is made. It has long been understood that this poses a risk of trojan-horse code execution if one modifies a table owned by an untrustworthy user. (Note that triggers, defaults, check constraints, etc. pose the same type of risk.) But functions in indexes pose extra danger because they will be executed by routine maintenance operations such as `VACUUM FULL`, which are commonly performed automatically under a superuser account. For example, a nefarious user can execute code with superuser privileges by setting up a trojan-horse index definition and waiting for the next routine vacuum. The fix arranges for standard maintenance operations (including `VACUUM`, `ANALYZE`, `REINDEX`, and `CLUSTER`) to execute as the table owner rather than the calling user, using the same privilege-switching mechanism already used for `SECURITY DEFINER` functions. To prevent bypassing this security measure, execution of `SET SESSION AUTHORIZATION` and `SET ROLE` is now forbidden within a `SECURITY DEFINER` context. (CVE-2007-6600)

- Repair assorted bugs in the regular-expression package (Tom, Will Drewry)

Suitably crafted regular-expression patterns could cause crashes, infinite or near-infinite looping, and/or massive memory consumption, all of which pose denial-of-service hazards for applications that ac-

cept regex search patterns from untrustworthy sources. (CVE-2007-4769, CVE-2007-4772, CVE-2007-6067)

- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

The fix that appeared for this in 8.2.5 was incomplete, as it plugged the hole for only some `dblink` functions. (CVE-2007-6601, CVE-2007-3278)

- Fix bugs in WAL replay for GIN indexes (Teodor)
- Fix GIN index build to work properly when `maintenance_work_mem` is 4GB or more (Tom)
- Update time zone data files to tzdata release 2007k (in particular, recent Argentina changes) (Tom)
- Improve planner's handling of LIKE/regex estimation in non-C locales (Tom)
- Fix planning-speed problem for deep outer-join nests, as well as possible poor choice of join order (Tom)
- Fix planner failure in some cases of `WHERE false AND var IN (SELECT ...)` (Tom)
- Make `CREATE TABLE ... SERIAL` and `ALTER SEQUENCE ... OWNED BY` not change the `currval()` state of the sequence (Tom)
- Preserve the tablespace and storage parameters of indexes that are rebuilt by `ALTER TABLE ... ALTER COLUMN TYPE` (Tom)
- Make archive recovery always start a new WAL timeline, rather than only when a recovery stop time was used (Simon)

This avoids a corner-case risk of trying to overwrite an existing archived copy of the last WAL segment, and seems simpler and cleaner than the original definition.

- Make `VACUUM` not use all of `maintenance_work_mem` when the table is too small for it to be useful (Alvaro)
- Fix potential crash in `translate()` when using a multibyte database encoding (Tom)
- Make `corr()` return the correct result for negative correlation values (Neil)
- Fix overflow in `extract(epoch from interval)` for intervals exceeding 68 years (Tom)
- Fix PL/Perl to not fail when a UTF-8 regular expression is used in a trusted function (Andrew)
- Fix PL/Perl to cope when platform's Perl defines type `bool` as `int` rather than `char` (Tom)

While this could theoretically happen anywhere, no standard build of Perl did things this way ... until Mac OS X 10.5.

- Fix PL/Python to work correctly with Python 2.5 on 64-bit machines (Marko Kreen)
- Fix PL/Python to not crash on long exception messages (Alvaro)
- Fix `pg_dump` to correctly handle inheritance child tables that have default expressions different from their parent's (Tom)
- Fix libpq crash when `PGPASSFILE` refers to a file that is not a plain file (Martin Pitt)
- `ecpg` parser fixes (Michael)
- Make `contrib/pgcrypto` defend against OpenSSL libraries that fail on keys longer than 128 bits; which is the case at least on some Solaris versions (Marko Kreen)

- Make `contrib/tablefunc`'s `crosstab()` handle NULL rowid as a category in its own right, rather than crashing (Joe)
- Fix `tsvector` and `tsquery` output routines to escape backslashes correctly (Teodor, Bruce)
- Fix crash of `to_tsvector()` on huge input strings (Teodor)
- Require a specific version of Autoconf to be used when re-generating the `configure` script (Peter)  
This affects developers and packagers only. The change was made to prevent accidental use of untested combinations of Autoconf and PostgreSQL versions. You can remove the version check if you really want to use a different Autoconf version, but it's your responsibility whether the result works or not.
- Update `gettimeofday` configuration check so that PostgreSQL can be built on newer versions of MinGW (Magnus)

## E.5. Release 8.2.5

**Release date:** 2007-09-17

This release contains a variety of fixes from 8.2.4.

### E.5.1. Migration to Version 8.2.5

A dump/restore is not required for those running 8.2.X.

### E.5.2. Changes

- Prevent index corruption when a transaction inserts rows and then aborts close to the end of a concurrent `VACUUM` on the same table (Tom)
- Fix `ALTER DOMAIN ADD CONSTRAINT` for cases involving domains over domains (Tom)
- Make `CREATE DOMAIN ... DEFAULT NULL` work properly (Tom)
- Fix some planner problems with outer joins, notably poor size estimation for `t1 LEFT JOIN t2 WHERE t2.col IS NULL` (Tom)
- Allow the `interval` data type to accept input consisting only of milliseconds or microseconds (Neil)
- Allow timezone name to appear before the year in `timestamp` input (Tom)
- Fixes for GIN indexes used by `/contrib/tsearch2` (Teodor)
- Speed up `rtree` index insertion (Teodor)
- Fix excessive logging of SSL error messages (Tom)
- Fix logging so that log messages are never interleaved when using the `syslogger` process (Andrew)

- Fix crash when `log_min_error_statement` logging runs out of memory (Tom)
- Fix incorrect handling of some foreign-key corner cases (Tom)
- Fix `stddev_pop(numeric)` and `var_pop(numeric)` (Tom)
- Prevent `REINDEX` and `CLUSTER` from failing due to attempting to process temporary tables of other sessions (Alvaro)
- Update the time zone database rules, particularly New Zealand's upcoming changes (Tom)
- Windows socket and semaphore improvements (Magnus)
- Make `pg_ctl -w` work properly in Windows service mode (Dave Page)
- Fix memory allocation bug when using MIT Kerberos on Windows (Magnus)
- Suppress timezone name (%Z) in log timestamps on Windows because of possible encoding mismatches (Tom)
- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)
- Restrict `/contrib/pgstattuple` functions to superusers, for security reasons (Tom)
- Do not let `/contrib/intarray` try to make its GIN opclass the default (this caused problems at dump/restore) (Tom)

## E.6. Release 8.2.4

**Release date:** 2007-04-23

This release contains a variety of fixes from 8.2.3, including a security fix.

### E.6.1. Migration to Version 8.2.4

A dump/restore is not required for those running 8.2.X.

### E.6.2. Changes

- Support explicit placement of the temporary-table schema within `search_path`, and disable searching it for functions and operators (Tom)

This is needed to allow a security-definer function to set a truly secure value of `search_path`. Without it, an unprivileged SQL user can use temporary objects to execute code with the privileges of the security-definer function (CVE-2007-2138). See `CREATE FUNCTION` for more information.

- Fix `shared_preload_libraries` for Windows by forcing reload in each backend (Korry Douglas)
- Fix `to_char()` so it properly upper/lower cases localized day or month names (Pavel Stehule)

- `/contrib/tsearch2` crash fixes (Teodor)
- Require `COMMIT PREPARED` to be executed in the same database as the transaction was prepared in (Heikki)
- Allow `pg_dump` to do binary backups larger than two gigabytes on Windows (Magnus)
- New traditional (Taiwan) Chinese FAQ (Zhou Daojing)
- Prevent the statistics collector from writing to disk too frequently (Tom)
- Fix potential-data-corruption bug in how `VACUUM FULL` handles `UPDATE` chains (Tom, Pavan Deolasee)
- Fix bug in domains that use array types (Tom)
- Fix `pg_dump` so it can dump a serial column's sequence using `-t` when not also dumping the owning table (Tom)
- Planner fixes, including improving outer join and bitmap scan selection logic (Tom)
- Fix possible wrong answers or crash when a PL/pgSQL function tries to `RETURN` from within an `EXCEPTION` block (Tom)
- Fix PANIC during enlargement of a hash index (Tom)
- Fix POSIX-style timezone specs to follow new USA DST rules (Tom)

## E.7. Release 8.2.3

**Release date:** 2007-02-07

This release contains two fixes from 8.2.2.

### E.7.1. Migration to Version 8.2.3

A dump/restore is not required for those running 8.2.X.

### E.7.2. Changes

- Remove overly-restrictive check for type length in constraints and functional indexes (Tom)
- Fix optimization so `MIN/MAX` in subqueries can again use indexes (Tom)

## E.8. Release 8.2.2

**Release date:** 2007-02-05

This release contains a variety of fixes from 8.2.1, including a security fix.

### E.8.1. Migration to Version 8.2.2

A dump/restore is not required for those running 8.2.X.

### E.8.2. Changes

- Remove security vulnerabilities that allowed connected users to read backend memory (Tom)

The vulnerabilities involve suppressing the normal check that a SQL function returns the data type it's declared to, and changing the data type of a table column (CVE-2007-0555, CVE-2007-0556). These errors can easily be exploited to cause a backend crash, and in principle might be used to read database content that the user should not be able to access.

- Fix not-so-rare-anymore bug wherein btree index page splits could fail due to choosing an infeasible split point (Heikki Linnakangas)
- Fix Borland C compile scripts (L Bayuk)
- Properly handle `to_char('CC')` for years ending in 00 (Tom)

Year 2000 is in the twentieth century, not the twenty-first.

- `/contrib/tsearch2` localization improvements (Tatsuo, Teodor)
- Fix incorrect permission check in `information_schema.key_column_usage` view (Tom)

The symptom is “relation with OID nnnnn does not exist” errors. To get this fix without using `initdb`, use `CREATE OR REPLACE VIEW` to install the corrected definition found in `share/information_schema.sql`. Note you will need to do this in each database.

- Improve `VACUUM` performance for databases with many tables (Tom)
- Fix for rare `Assert()` crash triggered by `UNION` (Tom)
- Fix potentially incorrect results from index searches using `ROW` inequality conditions (Tom)
- Tighten security of multi-byte character processing for UTF8 sequences over three bytes long (Tom)
- Fix bogus “permission denied” failures occurring on Windows due to attempts to `fsync` already-deleted files (Magnus, Tom)
- Fix bug that could cause the statistics collector to hang on Windows (Magnus)

This would in turn lead to `autovacuum` not working.

- Fix possible crashes when an already-in-use PL/pgSQL function is updated (Tom)
- Improve PL/pgSQL handling of domain types (Sergiy Vyshnevetskiy, Tom)

- Fix possible errors in processing PL/pgSQL exception blocks (Tom)

## E.9. Release 8.2.1

**Release date:** 2007-01-08

This release contains a variety of fixes from 8.2.

### E.9.1. Migration to Version 8.2.1

A dump/restore is not required for those running 8.2.

### E.9.2. Changes

- Fix crash with `SELECT ... LIMIT ALL` (also `LIMIT NULL`) (Tom)
- Several `/contrib/tsearch2` fixes (Teodor)
- On Windows, make log messages coming from the operating system use ASCII encoding (Hiroshi Saito)

This fixes a conversion problem when there is a mismatch between the encoding of the operating system and database server.

- Fix Windows linking of `pg_dump` using `win32.mak` (Hiroshi Saito)
- Fix planner mistakes for outer join queries (Tom)
- Fix several problems in queries involving sub-SELECTs (Tom)
- Fix potential crash in SPI during subtransaction abort (Tom)

This affects all PL functions since they all use SPI.

- Improve build speed of PDF documentation (Peter)
- Re-add JST (Japan) timezone abbreviation (Tom)
- Improve optimization decisions related to index scans (Tom)
- Have `psql` print multi-byte combining characters as before, rather than output as `\u` (Tom)
- Improve index usage of regular expressions that use parentheses (Tom)

This improves `psql \d` performance also.

- Make `pg_dumpall` assume that databases have public `CONNECT` privilege, when dumping from a pre-8.2 server (Tom)

This preserves the previous behavior that anyone can connect to a database if allowed by `pg_hba.conf`.

## E.10. Release 8.2

**Release date:** 2006-12-05

### E.10.1. Overview

This release adds many functionality and performance improvements that were requested by users, including:

- Query language enhancements including `INSERT/UPDATE/DELETE RETURNING`, `multirow VALUES` lists, and optional target-table alias in `UPDATE/DELETE`
- Index creation without blocking concurrent `INSERT/UPDATE/DELETE` operations
- Many query optimization improvements, including support for reordering outer joins
- Improved sorting performance with lower memory usage
- More efficient locking with better concurrency
- More efficient vacuuming
- Easier administration of warm standby servers
- New `FILLFACTOR` support for tables and indexes
- Monitoring, logging, and performance tuning additions
- More control over creating and dropping objects
- Table inheritance relationships can be defined for and removed from pre-existing tables
- `COPY TO` can copy the output of an arbitrary `SELECT` statement
- Array improvements, including nulls in arrays
- Aggregate-function improvements, including multiple-input aggregates and SQL:2003 statistical functions
- Many `contrib/` improvements

### E.10.2. Migration to Version 8.2

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

Observe the following incompatibilities:

- Set `escape_string_warning` to `on` by default (Bruce)  
This issues a warning if backslash escapes are used in non-escape (non-`E''`) strings.
- Change the row constructor syntax (`ROW(...)`) so that list elements `foo.*` will be expanded to a list of their member fields, rather than creating a nested row type field as formerly (Tom)

The new behavior is substantially more useful since it allows, for example, triggers to check for data changes with `IF row(new.*) IS DISTINCT FROM row(old.*)`. The old behavior is still available by omitting `.*`.

- Make row comparisons follow SQL standard semantics and allow them to be used in index scans (Tom)

Previously, `row =` and `<>` comparisons followed the standard but `< <= > >=` did not. A row comparison can now be used as an index constraint for a multicolumn index matching the row value.

- Make row `IS [NOT] NULL` tests follow SQL standard semantics (Tom)

The former behavior conformed to the standard for simple cases with `IS NULL`, but `IS NOT NULL` would return true if any row field was non-null, whereas the standard says it should return true only when all fields are non-null.

- Make `SET CONSTRAINT` affect only one constraint (Kris Jurka)

In previous releases, `SET CONSTRAINT` modified all constraints with a matching name. In this release, the schema search path is used to modify only the first matching constraint. A schema specification is also supported. This more nearly conforms to the SQL standard.

- Remove `RULE` permission for tables, for security reasons (Tom)

As of this release, only a table's owner can create or modify rules for the table. For backwards compatibility, `GRANT/REVOKE RULE` is still accepted, but it does nothing.

- Array comparison improvements (Tom)

Now array dimensions are also compared.

- Change array concatenation to match documented behavior (Tom)

This changes the previous behavior where concatenation would modify the array lower bound.

- Make command-line options of postmaster and postgres identical (Peter)

This allows the postmaster to pass arguments to each backend without using `-o`. Note that some options are now only available as long-form options, because there were conflicting single-letter options.

- Deprecate use of postmaster symbolic link (Peter)

postmaster and postgres commands now act identically, with the behavior determined by command-line options. The postmaster symbolic link is kept for compatibility, but is not really needed.

- Change `log_duration` to output even if the query is not output (Tom)

In prior releases, `log_duration` only printed if the query appeared earlier in the log.

- Make `to_char(time)` and `to_char(interval)` treat HH and HH12 as 12-hour intervals

Most applications should use HH24 unless they want a 12-hour display.

- Zero unmasked bits in conversion from INET to CIDR (Tom)

This ensures that the converted value is actually valid for CIDR.

- Remove `australian_timezones` configuration variable (Joachim Wieland)

This variable has been superseded by a more general facility for configuring timezone abbreviations.

- Improve cost estimation for nested-loop index scans (Tom)

This might eliminate the need to set unrealistically small values of `random_page_cost`. If you have been using a very small `random_page_cost`, please recheck your test cases.

- Change behavior of `pg_dump -n` and `-t` options. (Greg Sabino Mullane)  
See the `pg_dump` manual page for details.
- Change `libpq PQdsplen()` to return a useful value (Martijn van Oosterhout)
- Declare `libpq PQgetssl()` as returning `void *`, rather than `SSL *` (Martijn van Oosterhout)  
This allows applications to use the function without including the OpenSSL headers.
- C-language loadable modules must now include a `PG_MODULE_MAGIC` macro call for version compatibility checking (Martijn van Oosterhout)
- For security's sake, modules used by a PL/PerlU function are no longer available to PL/Perl functions (Andrew)

**Note:** This also implies that data can no longer be shared between a PL/Perl function and a PL/PerlU function. Some Perl installations have not been compiled with the correct flags to allow multiple interpreters to exist within a single process. In this situation PL/Perl and PL/PerlU cannot both be used in a single backend. The solution is to get a Perl installation which supports multiple interpreters.

- In `contrib/xml2/`, rename `xml_valid()` to `xml_is_well_formed()` (Tom)  
`xml_valid()` will remain for backward compatibility, but its behavior will change to do schema checking in a future release.
- Remove `contrib/ora2pg/`, now at <http://www.samse.fr/GPL/ora2pg>
- Remove contrib modules that have been migrated to PgFoundry: `adddepend`, `dbase`, `dbmirror`, `fulltextindex`, `mac`, `userlock`
- Remove abandoned contrib modules: `mSQL-interface`, `tips`
- Remove QNX and BEOS ports (Bruce)  
These ports no longer had active maintainers.

## E.10.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 8.2 and the previous major release.

### E.10.3.1. Performance Improvements

- Allow the planner to reorder outer joins in some circumstances (Tom)  
In previous releases, outer joins would always be evaluated in the order written in the query. This change allows the query optimizer to consider reordering outer joins, in cases where it can determine that the join order can be changed without altering the meaning of the query. This can make a considerable performance difference for queries involving multiple outer joins or mixed inner and outer joins.

- Improve efficiency of `IN` (list-of-expressions) clauses (Tom)
- Improve sorting speed and reduce memory usage (Simon, Tom)
- Improve subtransaction performance (Alvaro, Itagaki Takahiro, Tom)
- Add `FILLFACTOR` to table and index creation (ITAGAKI Takahiro)  
This leaves extra free space in each table or index page, allowing improved performance as the database grows. This is particularly valuable to maintain clustering.
- Increase default values for `shared_buffers` and `max_fsm_pages` (Andrew)
- Improve locking performance by breaking the lock manager tables into sections (Tom)  
This allows locking to be more fine-grained, reducing contention.
- Reduce locking requirements of sequential scans (Qingqing Zhou)
- Reduce locking required for database creation and destruction (Tom)
- Improve the optimizer's selectivity estimates for `LIKE`, `ILIKE`, and regular expression operations (Tom)
- Improve planning of joins to inherited tables and `UNION ALL` views (Tom)
- Allow constraint exclusion to be applied to inherited `UPDATE` and `DELETE` queries (Tom)  
`SELECT` already honored constraint exclusion.
- Improve planning of constant `WHERE` clauses, such as a condition that depends only on variables inherited from an outer query level (Tom)
- Protocol-level unnamed prepared statements are re-planned for each set of `BIND` values (Tom)  
This improves performance because the exact parameter values can be used in the plan.
- Speed up vacuuming of B-Tree indexes (Heikki Linnakangas, Tom)
- Avoid extra scan of tables without indexes during `VACUUM` (Greg Stark)
- Improve multicolumn GiST indexing (Oleg, Teodor)
- Remove dead index entries before B-Tree page split (Junji Teramoto)

### E.10.3.2. Server Changes

- Allow a forced switch to a new transaction log file (Simon, Tom)  
This is valuable for keeping warm standby slave servers in sync with the master. Transaction log file switching now also happens automatically during `pg_stop_backup()`. This ensures that all transaction log files needed for recovery can be archived immediately.
- Add WAL informational functions (Simon)  
Add functions for interrogating the current transaction log insertion point and determining WAL file-names from the hex WAL locations displayed by `pg_stop_backup()` and related functions.
- Improve recovery from a crash during WAL replay (Simon)  
The server now does periodic checkpoints during WAL recovery, so if there is a crash, future WAL recovery is shortened. This also eliminates the need for warm standby servers to replay the entire log since the base backup if they crash.

- Improve reliability of long-term WAL replay (Heikki, Simon, Tom)  
Formerly, trying to roll forward through more than 2 billion transactions would not work due to XID wraparound. This meant warm standby servers had to be reloaded from fresh base backups periodically.
- Add `archive_timeout` to force transaction log file switches at a given interval (Simon)  
This enforces a maximum replication delay for warm standby servers.
- Add native LDAP authentication (Magnus Hagander)  
This is particularly useful for platforms that do not support PAM, such as Windows.
- Add `GRANT CONNECT ON DATABASE` (Gevik Babakhani)  
This gives SQL-level control over database access. It works as an additional filter on top of the existing `pg_hba.conf` controls.
- Add support for SSL Certificate Revocation List (CRL) files (Libor Hohoš)  
The server and libpq both recognize CRL files now.
- GiST indexes are now clusterable (Teodor)
- Remove routine autovacuum server log entries (Bruce)  
`pg_stat_activity` now shows autovacuum activity.
- Track maximum XID age within individual tables, instead of whole databases (Alvaro)  
This reduces the overhead involved in preventing transaction ID wraparound, by avoiding unnecessary VACUUMs.
- Add last vacuum and analyze timestamp columns to the stats collector (Larry Rosenman)  
These values now appear in the `pg_stat_*_tables` system views.
- Improve performance of statistics monitoring, especially `stats_command_string` (Tom, Bruce)  
This release enables `stats_command_string` by default, now that its overhead is minimal. This means `pg_stat_activity` will now show all active queries by default.
- Add a `waiting` column to `pg_stat_activity` (Tom)  
This allows `pg_stat_activity` to show all the information included in the `ps` display.
- Add configuration parameter `update_process_title` to control whether the `ps` display is updated for every command (Bruce)  
On platforms where it is expensive to update the `ps` display, it might be worthwhile to turn this off and rely solely on `pg_stat_activity` for status information.
- Allow units to be specified in configuration settings (Peter)  
For example, you can now set `shared_buffers` to 32MB rather than mentally converting sizes.
- Add support for include directives in `postgresql.conf` (Joachim Wieland)
- Improve logging of protocol-level prepare/bind/execute messages (Bruce, Tom)  
Such logging now shows statement names, bind parameter values, and the text of the query being executed. Also, the query text is properly included in logged error messages when enabled by `log_min_error_statement`.
- Prevent `max_stack_depth` from being set to unsafe values

On platforms where we can determine the actual kernel stack depth limit (which is most), make sure that the initial default value of `max_stack_depth` is safe, and reject attempts to set it to unsafely large values.

- Enable highlighting of error location in query in more cases (Tom)

The server is now able to report a specific error location for some semantic errors (such as unrecognized column name), rather than just for basic syntax errors as before.

- Fix “failed to re-find parent key” errors in `VACUUM` (Tom)
- Clean out `pg_internal.init` cache files during server restart (Simon)

This avoids a hazard that the cache files might contain stale data after PITR recovery.

- Fix race condition for truncation of a large relation across a gigabyte boundary by `VACUUM` (Tom)
- Fix bug causing needless deadlock errors on row-level locks (Tom)
- Fix bugs affecting multi-gigabyte hash indexes (Tom)
- Each backend process is now its own process group leader (Tom)

This allows query cancel to abort subprocesses invoked from a backend or archive/recovery process.

### E.10.3.3. Query Changes

- Add `INSERT/UPDATE/DELETE RETURNING` (Jonah Harris, Tom)

This allows these commands to return values, such as the computed serial key for a new row. In the `UPDATE` case, values from the updated version of the row are returned.

- Add support for multiple-row `VALUES` clauses, per SQL standard (Joe, Tom)

This allows `INSERT` to insert multiple rows of constants, or queries to generate result sets using constants. For example, `INSERT ... VALUES (...), (...), ...`, and `SELECT * FROM (VALUES (...), (...), ...) AS alias(fl, ...)`.

- Allow `UPDATE` and `DELETE` to use an alias for the target table (Atsushi Ogawa)

The SQL standard does not permit an alias in these commands, but many database systems allow one anyway for notational convenience.

- Allow `UPDATE` to set multiple columns with a list of values (Susanne Ebrecht)

This is basically a short-hand for assigning the columns and values in pairs. The syntax is `UPDATE tab SET (column, ...) = (val, ...)`.

- Make row comparisons work per standard (Tom)

The forms `<`, `<=`, `>`, `>=` now compare rows lexicographically, that is, compare the first elements, if equal compare the second elements, and so on. Formerly they expanded to an `AND` condition across all the elements, which was neither standard nor very useful.

- Add `CASCADE` option to `TRUNCATE` (Joachim Wieland)

This causes `TRUNCATE` to automatically include all tables that reference the specified table(s) via foreign keys. While convenient, this is a dangerous tool — use with caution!

- Support `FOR UPDATE` and `FOR SHARE` in the same `SELECT` command (Tom)

- Add `IS NOT DISTINCT FROM` (Pavel Stehule)  
This operator is similar to equality (`=`), but evaluates to true when both left and right operands are `NULL`, and to false when just one is, rather than yielding `NULL` in these cases.
- Improve the length output used by `UNION/INTERSECT/EXCEPT` (Tom)  
When all corresponding columns are of the same defined length, that length is used for the result, rather than a generic length.
- Allow `ILIKE` to work for multi-byte encodings (Tom)  
Internally, `ILIKE` now calls `lower()` and then uses `LIKE`. Locale-specific regular expression patterns still do not work in these encodings.
- Enable `standard_conforming_strings` to be turned on (Kevin Grittner)  
This allows backslash escaping in strings to be disabled, making PostgreSQL more standards-compliant. The default is `off` for backwards compatibility, but future releases will default this to `on`.
- Do not flatten subqueries that contain `volatile` functions in their target lists (Jaime Casanova)  
This prevents surprising behavior due to multiple evaluation of a `volatile` function (such as `random()` or `nextval()`). It might cause performance degradation in the presence of functions that are unnecessarily marked as `volatile`.
- Add system views `pg_prepared_statements` and `pg_cursors` to show prepared statements and open cursors (Joachim Wieland, Neil)  
These are very useful in pooled connection setups.
- Support portal parameters in `EXPLAIN` and `EXECUTE` (Tom)  
This allows, for example, JDBC `?` parameters to work in these commands.
- If SQL-level `PREPARE` parameters are unspecified, infer their types from the content of the query (Neil)  
Protocol-level `PREPARE` already did this.
- Allow `LIMIT` and `OFFSET` to exceed two billion (Dhanaraj M)

### E.10.3.4. Object Manipulation Changes

- Add `TABLESPACE` clause to `CREATE TABLE AS` (Neil)  
This allows a tablespace to be specified for the new table.
- Add `ON COMMIT` clause to `CREATE TABLE AS` (Neil)  
This allows temporary tables to be truncated or dropped on transaction commit. The default behavior is for the table to remain until the session ends.
- Add `INCLUDING CONSTRAINTS` to `CREATE TABLE LIKE` (Greg Stark)  
This allows easy copying of `CHECK` constraints to a new table.
- Allow the creation of placeholder (shell) types (Martijn van Oosterhout)

A shell type declaration creates a type name, without specifying any of the details of the type. Making a shell type is useful because it allows cleaner declaration of the type's input/output functions, which must exist before the type can be defined “for real”. The syntax is `CREATE TYPE typename`.

- Aggregate functions now support multiple input parameters (Sergey Kopolov, Tom)
- Add new aggregate creation syntax (Tom)

The new syntax is `CREATE AGGREGATE aggrname (input_type) (parameter_list)`. This more naturally supports the new multi-parameter aggregate functionality. The previous syntax is still supported.

- Add `ALTER ROLE PASSWORD NULL` to remove a previously set role password (Peter)
- Add `DROP object IF EXISTS` for many object types (Andrew)

This allows `DROP` operations on non-existent objects without generating an error.

- Add `DROP OWNED` to drop all objects owned by a role (Alvaro)
- Add `REASSIGN OWNED` to reassign ownership of all objects owned by a role (Alvaro)

This, and `DROP OWNED` above, facilitate dropping roles.

- Add `GRANT ON SEQUENCE` syntax (Bruce)

This was added for setting sequence-specific permissions. `GRANT ON TABLE` for sequences is still supported for backward compatibility.

- Add `USAGE` permission for sequences that allows only `currval()` and `nextval()`, not `setval()` (Bruce)

`USAGE` permission allows more fine-grained control over sequence access. Granting `USAGE` allows users to increment a sequence, but prevents them from setting the sequence to an arbitrary value using `setval()`.

- Add `ALTER TABLE [ NO ] INHERIT` (Greg Stark)

This allows inheritance to be adjusted dynamically, rather than just at table creation and destruction. This is very valuable when using inheritance to implement table partitioning.

- Allow comments on global objects to be stored globally (Kris Jurka)

Previously, comments attached to databases were stored in individual databases, making them ineffective, and there was no provision at all for comments on roles or tablespaces. This change adds a new shared catalog `pg_shdescription` and stores comments on databases, roles, and tablespaces therein.

### E.10.3.5. Utility Command Changes

- Add option to allow indexes to be created without blocking concurrent writes to the table (Greg Stark, Tom)

The new syntax is `CREATE INDEX CONCURRENTLY`. The default behavior is still to block table modification while a index is being created.

- Provide advisory locking functionality (Abhijit Menon-Sen, Tom)

This is a new locking API designed to replace what used to be in `/contrib/userlock`. The `userlock` code is now on `pgfoundry`.

- Allow `COPY` to dump a `SELECT` query (Zoltan Boszormenyi, Karel Zak)  
This allows `COPY` to dump arbitrary SQL queries. The syntax is `COPY (SELECT ...) TO`.
- Make the `COPY` command return a command tag that includes the number of rows copied (Volkan YAZICI)
- Allow `VACUUM` to expire rows without being affected by other concurrent `VACUUM` operations (Hannu Krossing, Alvaro, Tom)
- Make `initdb` detect the operating system locale and set the default `DateStyle` accordingly (Peter)  
This makes it more likely that the installed `postgresql.conf` `DateStyle` value will be as desired.
- Reduce number of progress messages displayed by `initdb` (Tom)

### E.10.3.6. Date/Time Changes

- Allow full timezone names in `timestamp` input values (Joachim Wieland)  
For example, `'2006-05-24 21:11 America/New_York'::timestamptz`.
- Support configurable timezone abbreviations (Joachim Wieland)  
A desired set of timezone abbreviations can be chosen via the configuration parameter `timezone_abbreviations`.
- Add `pg_timezone_abbrevs` and `pg_timezone_names` views to show supported timezones (Magnus Hagander)
- Add `clock_timestamp()`, `statement_timestamp()`, and `transaction_timestamp()` (Bruce)  
`clock_timestamp()` is the current wall-clock time, `statement_timestamp()` is the time the current statement arrived at the server, and `transaction_timestamp()` is an alias for `now()`.
- Allow `to_char()` to print localized month and day names (Euler Taveira de Oliveira)
- Allow `to_char(time)` and `to_char(interval)` to output AM/PM specifications (Bruce)  
Intervals and times are treated as 24-hour periods, e.g. `25 hours` is considered AM.
- Add new function `justify_interval()` to adjust interval units (Mark Dilger)
- Allow timezone offsets up to 14:59 away from GMT  
Kiribati uses GMT+14, so we'd better accept that.
- Interval computation improvements (Michael Glaesemann, Bruce)

### E.10.3.7. Other Data Type and Function Changes

- Allow arrays to contain `NULL` elements (Tom)
- Allow assignment to array elements not contiguous with the existing entries (Tom)  
The intervening array positions will be filled with nulls. This is per SQL standard.
- New built-in operators for array-subset comparisons (`@>`, `<@`, `&&`) (Teodor, Tom)

These operators can be indexed for many data types using GiST or GIN indexes.

- Add convenient arithmetic operations on `INET/CIDR` values (Stephen R. van den Berg)

The new operators are `&` (and), `|` (or), `~` (not), `inet + int8`, `inet - int8`, and `inet - inet`.

- Add new aggregate functions from SQL:2003 (Neil)

The new functions are `var_pop()`, `var_samp()`, `stddev_pop()`, and `stddev_samp()`. `var_samp()` and `stddev_samp()` are merely renamings of the existing aggregates `variance()` and `stddev()`. The latter names remain available for backward compatibility.

- Add SQL:2003 statistical aggregates (Sergey Kopolov)

New functions: `regr_intercept()`, `regr_slope()`, `regr_r2()`, `corr()`, `covar_samp()`, `covar_pop()`, `regr_avgx()`, `regr_avgy()`, `regr_sxy()`, `regr_sxx()`, `regr_syy()`, `regr_count()`.

- Allow domains to be based on other domains (Tom)
- Properly enforce domain `CHECK` constraints everywhere (Neil, Tom)

For example, the result of a user-defined function that is declared to return a domain type is now checked against the domain's constraints. This closes a significant hole in the domain implementation.

- Fix problems with dumping renamed `SERIAL` columns (Tom)

The fix is to dump a `SERIAL` column by explicitly specifying its `DEFAULT` and sequence elements, and reconstructing the `SERIAL` column on reload using a new `ALTER SEQUENCE OWNED BY` command. This also allows dropping a `SERIAL` column specification.

- Add a server-side sleep function `pg_sleep()` (Joachim Wieland)
- Add all comparison operators for the `tid` (tuple id) data type (Mark Kirkwood, Greg Stark, Tom)

### E.10.3.8. PL/PgSQL Server-Side Language Changes

- Add `TG_table_name` and `TG_table_schema` to trigger parameters (Andrew)

`TG_relname` is now deprecated. Comparable changes have been made in the trigger parameters for the other PLs as well.

- Allow `FOR` statements to return values to scalars as well as records and row types (Pavel Stehule)
- Add a `BY` clause to the `FOR` loop, to control the iteration increment (Jaime Casanova)
- Add `STRICT` to `SELECT INTO` (Matt Miller)

`STRICT` mode throws an exception if more or less than one row is returned by the `SELECT`, for Oracle PL/SQL compatibility.

### E.10.3.9. PL/Perl Server-Side Language Changes

- Add `table_name` and `table_schema` to trigger parameters (Adam Sjøgren)
- Add prepared queries (Dmitry Karasik)

- Make `$_TD` trigger data a global variable (Andrew)

Previously, it was lexical, which caused unexpected sharing violations.

- Run PL/Perl and PL/PerlU in separate interpreters, for security reasons (Andrew)

In consequence, they can no longer share data nor loaded modules. Also, if Perl has not been compiled with the requisite flags to allow multiple interpreters, only one of these languages can be used in any given backend process.

### E.10.3.10. PL/Python Server-Side Language Changes

- Named parameters are passed as ordinary variables, as well as in the `args[]` array (Sven Suursoho)
- Add `table_name` and `table_schema` to trigger parameters (Andrew)
- Allow returning of composite types and result sets (Sven Suursoho)
- Return result-set as `list`, `iterator`, or `generator` (Sven Suursoho)
- Allow functions to return `void` (Neil)
- Python 2.5 is now supported (Tom)

### E.10.3.11. psql Changes

- Add new command `\password` for changing role password with client-side password encryption (Peter)
- Allow `\c` to connect to a new host and port number (David, Volkan YAZICI)
- Add tablespace display to `\l+` (Philip Yarra)
- Improve `\df slash` command to include the argument names and modes (`OUT` or `INOUT`) of the function (David Fetter)
- Support binary `COPY` (Andreas Pflug)
- Add option to run the entire session in a single transaction (Simon)  
Use option `-1` or `--single-transaction`.
- Support for automatically retrieving `SELECT` results in batches using a cursor (Chris Mair)  
This is enabled using `\set FETCH_COUNT n`. This feature allows large result sets to be retrieved in `psql` without attempting to buffer the entire result set in memory.
- Make multi-line values align in the proper column (Martijn van Oosterhout)  
Field values containing newlines are now displayed in a more readable fashion.
- Save multi-line statements as a single entry, rather than one line at a time (Sergey E. Koposov)  
This makes up-arrow recall of queries easier. (This is not available on Windows, because that platform uses the native command-line editing present in the operating system.)
- Make the line counter 64-bit so it can handle files with more than two billion lines (David Fetter)

- Report both the returned data and the command status tag for `INSERT/UPDATE/DELETE RETURNING` (Tom)

### E.10.3.12. `pg_dump` Changes

- Allow complex selection of objects to be included or excluded by `pg_dump` (Greg Sabino Mullane)  
`pg_dump` now supports multiple `-n` (schema) and `-t` (table) options, and adds `-N` and `-T` options to exclude objects. Also, the arguments of these switches can now be wild-card expressions rather than single object names, for example `-t 'foo*'`, and a schema can be part of a `-t` or `-T` switch, for example `-t schema1.table1`.
- Add `pg_restore --no-data-for-failed-tables` option to suppress loading data if table creation failed (i.e., the table already exists) (Martin Pitt)
- Add `pg_restore` option to run the entire session in a single transaction (Simon)  
 Use option `-1` or `--single-transaction`.

### E.10.3.13. `libpq` Changes

- Add `PQencryptPassword()` to encrypt passwords (Tom)  
 This allows passwords to be sent pre-encrypted for commands like `ALTER ROLE ... PASSWORD`.
- Add function `PQisthreadsafe()` (Bruce)  
 This allows applications to query the thread-safety status of the library.
- Add `PQdescribePrepared()`, `PQdescribePortal()`, and related functions to return information about previously prepared statements and open cursors (Volkan YAZICI)
- Allow LDAP lookups from `pg_service.conf` (Laurenz Albe)
- Allow a hostname in `~/.pgpass` to match the default socket directory (Bruce)  
 A blank hostname continues to match any Unix-socket connection, but this addition allows entries that are specific to one of several postmasters on the machine.

### E.10.3.14. `ecpg` Changes

- Allow `SHOW` to put its result into a variable (Joachim Wieland)
- Add `COPY TO STDOUT` (Joachim Wieland)
- Add regression tests (Joachim Wieland, Michael)
- Major source code cleanups (Joachim Wieland, Michael)

### E.10.3.15. Windows Port

- Allow MSVC to compile the PostgreSQL server (Magnus, Hiroshi Saito)
- Add MSVC support for utility commands and `pg_dump` (Hiroshi Saito)
- Add support for Windows code pages 1253, 1254, 1255, and 1257 (Kris Jurka)
- Drop privileges on startup, so that the server can be started from an administrative account (Magnus)
- Stability fixes (Qingqing Zhou, Magnus)
- Add native semaphore implementation (Qingqing Zhou)

The previous code mimicked SysV semaphores.

### E.10.3.16. Source Code Changes

- Add GIN (Generalized Inverted iNdex) index access method (Teodor, Oleg)
- Remove R-tree indexing (Tom)
 

Rtree has been re-implemented using GiST. Among other differences, this means that rtree indexes now have support for crash recovery via write-ahead logging (WAL).
- Reduce libraries needlessly linked into the backend (Martijn van Oosterhout, Tom)
- Add a configure flag to allow libedit to be preferred over GNU readline (Bruce)
 

Use configure `--with-libedit-preferred`.
- Allow installation into directories containing spaces (Peter)
- Improve ability to relocate installation directories (Tom)
- Add support for Solaris x86\_64 using the Solaris compiler (Pierre Girard, Theo Schlossnagle, Bruce)
- Add DTrace support (Robert Lor)
- Add `PG_VERSION_NUM` for use by third-party applications wanting to test the backend version in C using `>` and `<` comparisons (Bruce)
- Add `XLOG_BLCKSZ` as independent from `BLCKSZ` (Mark Wong)
- Add `LWLOCK_STATS` define to report locking activity (Tom)
- Emit warnings for unknown configure options (Martijn van Oosterhout)
- Add server support for “plugin” libraries that can be used for add-on tasks such as debugging and performance measurement (Korry Douglas)

This consists of two features: a table of “rendezvous variables” that allows separately-loaded shared libraries to communicate, and a new configuration parameter `local_preload_libraries` that allows libraries to be loaded into specific sessions without explicit cooperation from the client application. This allows external add-ons to implement features such as a PL/PostgreSQL debugger.

- Rename existing configuration parameter `preload_libraries` to `shared_preload_libraries` (Tom)

This was done for clarity in comparison to `local_preload_libraries`.

- Add new configuration parameter `server_version_num` (Greg Sabino Mullane)  
This is like `server_version`, but is an integer, e.g. 80200. This allows applications to make version checks more easily.
- Add a configuration parameter `seq_page_cost` (Tom)
- Re-implement the regression test script as a C program (Magnus, Tom)
- Allow loadable modules to allocate shared memory and lightweight locks (Marc Munro)
- Add automatic initialization and finalization of dynamically loaded libraries (Ralf Engelschall, Tom)  
New functions `_PG_init()` and `_PG_fini()` are called if the library defines such symbols. Hence we no longer need to specify an initialization function in `shared_preload_libraries`; we can assume that the library used the `_PG_init()` convention instead.
- Add `PG_MODULE_MAGIC` header block to all shared object files (Martijn van Oosterhout)  
The magic block prevents version mismatches between loadable object files and servers.
- Add shared library support for AIX (Laurenz Albe)
- New XML documentation section (Bruce)

### E.10.3.17. Contrib Changes

- Major tsearch2 improvements (Oleg, Teodor)
  - multibyte encoding support, including UTF8
  - query rewriting support
  - improved ranking functions
  - thesaurus dictionary support
  - Ispell dictionaries now recognize MySpell format, used by OpenOffice
  - GIN support
- Add adminpack module containing Pgadmin administration functions (Dave)  
These functions provide additional file system access routines not present in the default PostgreSQL server.
- Add sslinfo module (Victor Wagner)  
Reports information about the current connection's SSL certificate.
- Add pgrowlocks module (Tatsuo)  
This shows row locking information for a specified table.
- Add hstore module (Oleg, Teodor)
- Add isn module, replacing isbn\_issn (Jeremy Kronuz)  
This new implementation supports EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials).
- Add index information functions to pgstattuple (ITAGAKI Takahiro, Satoshi Nagayasu)

- Add `pg_freespacemap` module to display free space map information (Mark Kirkwood)
- `pgcrypto` now has all planned functionality (Marko Kreen)
  - Include `iMath` library in `pgcrypto` to have the public-key encryption functions always available.
  - Add SHA224 algorithm that was missing in OpenBSD code.
  - Activate builtin code for SHA224/256/384/512 hashes on older OpenSSL to have those algorithms always available.
  - New function `gen_random_bytes()` that returns cryptographically strong randomness. Useful for generating encryption keys.
  - Remove `digest_exists()`, `hmac_exists()` and `cipher_exists()` functions.
- Improvements to `cube` module (Joshua Reich)
 

New functions are `cube(float[])`, `cube(float[], float[])`, and `cube_subset(cube, int4[])`.
- Add async query capability to `dblink` (Kai Londenberger, Joe Conway)
- New operators for array-subset comparisons (`@>`, `<@`, `&&`) (Tom)
 

Various contrib packages already had these operators for their datatypes, but the naming wasn't consistent. We have now added consistently named array-subset comparison operators to the core code and all the contrib packages that have such functionality. (The old names remain available, but are deprecated.)
- Add uninstall scripts for all contrib packages that have install scripts (David, Josh Drake)

## E.11. Release 8.1.11

**Release date:** 2008-01-07

This release contains a variety of fixes from 8.1.10, including fixes for significant security issues.

This is the last 8.1.X release for which the PostgreSQL community will produce binary packages for Windows. Windows users are encouraged to move to 8.2.X or later, since there are Windows-specific fixes in 8.2.X that are impractical to back-port. 8.1.X will continue to be supported on other platforms.

### E.11.1. Migration to Version 8.1.11

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

## E.11.2. Changes

- Prevent functions in indexes from executing with the privileges of the user running `VACUUM`, `ANALYZE`, etc (Tom)

Functions used in index expressions and partial-index predicates are evaluated whenever a new table entry is made. It has long been understood that this poses a risk of trojan-horse code execution if one modifies a table owned by an untrustworthy user. (Note that triggers, defaults, check constraints, etc. pose the same type of risk.) But functions in indexes pose extra danger because they will be executed by routine maintenance operations such as `VACUUM FULL`, which are commonly performed automatically under a superuser account. For example, a nefarious user can execute code with superuser privileges by setting up a trojan-horse index definition and waiting for the next routine vacuum. The fix arranges for standard maintenance operations (including `VACUUM`, `ANALYZE`, `REINDEX`, and `CLUSTER`) to execute as the table owner rather than the calling user, using the same privilege-switching mechanism already used for `SECURITY DEFINER` functions. To prevent bypassing this security measure, execution of `SET SESSION AUTHORIZATION` and `SET ROLE` is now forbidden within a `SECURITY DEFINER` context. (CVE-2007-6600)

- Repair assorted bugs in the regular-expression package (Tom, Will Drewry)

Suitably crafted regular-expression patterns could cause crashes, infinite or near-infinite looping, and/or massive memory consumption, all of which pose denial-of-service hazards for applications that accept regex search patterns from untrustworthy sources. (CVE-2007-4769, CVE-2007-4772, CVE-2007-6067)

- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

The fix that appeared for this in 8.1.10 was incomplete, as it plugged the hole for only some `dblink` functions. (CVE-2007-6601, CVE-2007-3278)

- Update time zone data files to tzdata release 2007k (in particular, recent Argentina changes) (Tom)
- Improve planner's handling of `LIKE`/regex estimation in non-C locales (Tom)
- Fix planner failure in some cases of `WHERE false AND var IN (SELECT ...)` (Tom)
- Preserve the tablespace of indexes that are rebuilt by `ALTER TABLE ... ALTER COLUMN TYPE` (Tom)
- Make archive recovery always start a new WAL timeline, rather than only when a recovery stop time was used (Simon)

This avoids a corner-case risk of trying to overwrite an existing archived copy of the last WAL segment, and seems simpler and cleaner than the original definition.

- Make `VACUUM` not use all of `maintenance_work_mem` when the table is too small for it to be useful (Alvaro)
- Fix potential crash in `translate()` when using a multibyte database encoding (Tom)
- Fix overflow in `extract(epoch from interval)` for intervals exceeding 68 years (Tom)
- Fix PL/Perl to not fail when a UTF-8 regular expression is used in a trusted function (Andrew)
- Fix PL/Perl to cope when platform's Perl defines type `bool` as `int` rather than `char` (Tom)

While this could theoretically happen anywhere, no standard build of Perl did things this way ... until Mac OS X 10.5.

- Fix PL/Python to not crash on long exception messages (Alvaro)
- Fix `pg_dump` to correctly handle inheritance child tables that have default expressions different from their parent's (Tom)
- Fix libpq crash when `PGPASSFILE` refers to a file that is not a plain file (Martin Pitt)
- `ecpg` parser fixes (Michael)
- Make `contrib/pgcrypto` defend against OpenSSL libraries that fail on keys longer than 128 bits; which is the case at least on some Solaris versions (Marko Kreen)
- Make `contrib/tablefunc`'s `crosstab()` handle NULL rowid as a category in its own right, rather than crashing (Joe)
- Fix `tsvector` and `tsquery` output routines to escape backslashes correctly (Teodor, Bruce)
- Fix crash of `to_tsvector()` on huge input strings (Teodor)
- Require a specific version of Autoconf to be used when re-generating the `configure` script (Peter)

This affects developers and packagers only. The change was made to prevent accidental use of untested combinations of Autoconf and PostgreSQL versions. You can remove the version check if you really want to use a different Autoconf version, but it's your responsibility whether the result works or not.

## E.12. Release 8.1.10

**Release date:** 2007-09-17

This release contains a variety of fixes from 8.1.9.

### E.12.1. Migration to Version 8.1.10

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### E.12.2. Changes

- Prevent index corruption when a transaction inserts rows and then aborts close to the end of a concurrent `VACUUM` on the same table (Tom)
- Make `CREATE DOMAIN ... DEFAULT NULL` work properly (Tom)
- Allow the `interval` data type to accept input consisting only of milliseconds or microseconds (Neil)
- Speed up `rtree` index insertion (Teodor)

- Fix excessive logging of SSL error messages (Tom)
- Fix logging so that log messages are never interleaved when using the sysloger process (Andrew)
- Fix crash when `log_min_error_statement` logging runs out of memory (Tom)
- Fix incorrect handling of some foreign-key corner cases (Tom)
- Prevent `REINDEX` and `CLUSTER` from failing due to attempting to process temporary tables of other sessions (Alvaro)
- Update the time zone database rules, particularly New Zealand's upcoming changes (Tom)
- Windows socket improvements (Magnus)
- Suppress timezone name (%Z) in log timestamps on Windows because of possible encoding mismatches (Tom)
- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

## E.13. Release 8.1.9

**Release date:** 2007-04-23

This release contains a variety of fixes from 8.1.8, including a security fix.

### E.13.1. Migration to Version 8.1.9

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### E.13.2. Changes

- Support explicit placement of the temporary-table schema within `search_path`, and disable searching it for functions and operators (Tom)

This is needed to allow a security-definer function to set a truly secure value of `search_path`. Without it, an unprivileged SQL user can use temporary objects to execute code with the privileges of the security-definer function (CVE-2007-2138). See `CREATE FUNCTION` for more information.

- `/contrib/tsearch2` crash fixes (Teodor)
- Require `COMMIT PREPARED` to be executed in the same database as the transaction was prepared in (Heikki)
- Fix potential-data-corruption bug in how `VACUUM FULL` handles `UPDATE` chains (Tom, Pavan Deolasee)
- Planner fixes, including improving outer join and bitmap scan selection logic (Tom)

- Fix PANIC during enlargement of a hash index (bug introduced in 8.1.6) (Tom)
- Fix POSIX-style timezone specs to follow new USA DST rules (Tom)

## **E.14. Release 8.1.8**

**Release date:** 2007-02-07

This release contains one fix from 8.1.7.

### **E.14.1. Migration to Version 8.1.8**

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### **E.14.2. Changes**

- Remove overly-restrictive check for type length in constraints and functional indexes(Tom)

## **E.15. Release 8.1.7**

**Release date:** 2007-02-05

This release contains a variety of fixes from 8.1.6, including a security fix.

### **E.15.1. Migration to Version 8.1.7**

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### **E.15.2. Changes**

- Remove security vulnerabilities that allowed connected users to read backend memory (Tom)

The vulnerabilities involve suppressing the normal check that a SQL function returns the data type it's declared to, and changing the data type of a table column (CVE-2007-0555, CVE-2007-0556). These errors can easily be exploited to cause a backend crash, and in principle might be used to read database content that the user should not be able to access.

- Fix rare bug wherein btree index page splits could fail due to choosing an infeasible split point (Heikki Linnakangas)
- Improve `VACUUM` performance for databases with many tables (Tom)
- Fix autovacuum to avoid leaving non-permanent transaction IDs in non-connectable databases (Alvaro)  
This bug affects the 8.1 branch only.
- Fix for rare `Assert()` crash triggered by `UNION` (Tom)
- Tighten security of multi-byte character processing for UTF8 sequences over three bytes long (Tom)
- Fix bogus “permission denied” failures occurring on Windows due to attempts to `fsync` already-deleted files (Magnus, Tom)
- Fix possible crashes when an already-in-use PL/pgSQL function is updated (Tom)

## E.16. Release 8.1.6

**Release date:** 2007-01-08

This release contains a variety of fixes from 8.1.5.

### E.16.1. Migration to Version 8.1.6

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### E.16.2. Changes

- Improve handling of `getaddrinfo()` on AIX (Tom)  
This fixes a problem with starting the statistics collector, among other things.
- Fix `pg_restore` to handle a tar-format backup that contains large objects (blobs) with comments (Tom)
- Fix “failed to re-find parent key” errors in `VACUUM` (Tom)
- Clean out `pg_internal.init` cache files during server restart (Simon)  
This avoids a hazard that the cache files might contain stale data after PITR recovery.
- Fix race condition for truncation of a large relation across a gigabyte boundary by `VACUUM` (Tom)

- Fix bug causing needless deadlock errors on row-level locks (Tom)
- Fix bugs affecting multi-gigabyte hash indexes (Tom)
- Fix possible deadlock in Windows signal handling (Teodor)
- Fix error when constructing an `ARRAY[]` made up of multiple empty elements (Tom)
- Fix ecpg memory leak during connection (Michael)
- Fix for Darwin (OS X) compilation (Tom)
- `to_number()` and `to_char(numeric)` are now `STABLE`, not `IMMUTABLE`, for new `initdb` installs (Tom)

This is because `lc_numeric` can potentially change the output of these functions.

- Improve index usage of regular expressions that use parentheses (Tom)

This improves `psql \d` performance also.

- Update timezone database

This affects Australian and Canadian daylight-savings rules in particular.

## E.17. Release 8.1.5

**Release date:** 2006-10-16

This release contains a variety of fixes from 8.1.4.

### E.17.1. Migration to Version 8.1.5

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### E.17.2. Changes

- Disallow aggregate functions in `UPDATE` commands, except within sub-`SELECT`s (Tom)

The behavior of such an aggregate was unpredictable, and in 8.1.X could cause a crash, so it has been disabled. The SQL standard does not allow this either.

- Fix core dump when an untyped literal is taken as `ANYARRAY`
- Fix core dump in duration logging for extended query protocol when a `COMMIT` or `ROLLBACK` is executed
- Fix mishandling of `AFTER` triggers when query contains a SQL function returning multiple rows (Tom)
- Fix `ALTER TABLE ... TYPE` to recheck `NOT NULL` for `USING` clause (Tom)

- Fix `string_to_array()` to handle overlapping matches for the separator string

For example, `string_to_array('123xx456xxx789', 'xx')`.

- Fix `to_timestamp()` for AM/PM formats (Bruce)
  - Fix autovacuum's calculation that decides whether `ANALYZE` is needed (Alvaro)
  - Fix corner cases in pattern matching for `psql`'s `\d` commands
  - Fix index-corrupting bugs in `/contrib/ltree` (Teodor)
  - Numerous robustness fixes in `ecpg` (Joachim Wieland)
  - Fix backslash escaping in `/contrib/dbmirror`
  - Minor fixes in `/contrib/dblink` and `/contrib/tsearch2`
  - Efficiency improvements in hash tables and bitmap index scans (Tom)
  - Fix instability of statistics collection on Windows (Tom, Andrew)
  - Fix `statement_timeout` to use the proper units on Win32 (Bruce)
- In previous Win32 8.1.X versions, the delay was off by a factor of 100.
- Fixes for MSVC and Borland C++ compilers (Hiroshi Saito)
  - Fixes for AIX and Intel compilers (Tom)
  - Fix rare bug in continuous archiving (Tom)

## E.18. Release 8.1.4

**Release date:** 2006-05-23

This release contains a variety of fixes from 8.1.3, including patches for extremely serious security issues.

### E.18.1. Migration to Version 8.1.4

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

Full security against the SQL-injection attacks described in CVE-2006-2313 and CVE-2006-2314 might require changes in application code. If you have applications that embed untrustworthy strings into SQL commands, you should examine them as soon as possible to ensure that they are using recommended escaping techniques. In most cases, applications should be using subroutines provided by libraries or drivers (such as `libpq`'s `PQescapeStringConn()`) to perform string escaping, rather than relying on *ad hoc* code to do it.

## E.18.2. Changes

- Change the server to reject invalidly-encoded multibyte characters in all cases (Tatsuo, Tom)

While PostgreSQL has been moving in this direction for some time, the checks are now applied uniformly to all encodings and all textual input, and are now always errors not merely warnings. This change defends against SQL-injection attacks of the type described in CVE-2006-2313.

- Reject unsafe uses of `\'` in string literals

As a server-side defense against SQL-injection attacks of the type described in CVE-2006-2314, the server now only accepts `"` and not `\'` as a representation of ASCII single quote in SQL string literals. By default, `\'` is rejected only when `client_encoding` is set to a client-only encoding (SJIS, BIG5, GBK, GB18030, or UHC), which is the scenario in which SQL injection is possible. A new configuration parameter `backslash_quote` is available to adjust this behavior when needed. Note that full security against CVE-2006-2314 might require client-side changes; the purpose of `backslash_quote` is in part to make it obvious that insecure clients are insecure.

- Modify `libpq`'s string-escaping routines to be aware of encoding considerations and `standard_conforming_strings`

This fixes `libpq`-using applications for the security issues described in CVE-2006-2313 and CVE-2006-2314, and also future-proofs them against the planned changeover to SQL-standard string literal syntax. Applications that use multiple PostgreSQL connections concurrently should migrate to `PQescapeStringConn()` and `PQescapeByteaConn()` to ensure that escaping is done correctly for the settings in use in each database connection. Applications that do string escaping “by hand” should be modified to rely on library routines instead.

- Fix weak key selection in `pgcrypto` (Marko Kreen)

Errors in `fortuna` PRNG reseeding logic could cause a predictable session key to be selected by `pgp_sym_encrypt()` in some cases. This only affects non-OpenSSL-using builds.

- Fix some incorrect encoding conversion functions

`win1251_to_iso`, `win866_to_iso`, `euc_tw_to_big5`, `euc_tw_to_mic`, `mic_to_euc_tw` were all broken to varying extents.

- Clean up stray remaining uses of `\'` in strings (Bruce, Jan)
- Make autovacuum visible in `pg_stat_activity` (Alvaro)
- Disable `full_page_writes` (Tom)

In certain cases, having `full_page_writes` off would cause crash recovery to fail. A proper fix will appear in 8.2; for now it's just disabled.

- Various planner fixes, particularly for bitmap index scans and MIN/MAX optimization (Tom)
- Fix incorrect optimization in merge join (Tom)

Outer joins could sometimes emit multiple copies of unmatched rows.

- Fix crash from using and modifying a `plpgsql` function in the same transaction
- Fix WAL replay for case where a B-Tree index has been truncated
- Fix `SIMILAR TO` for patterns involving `|` (Tom)

- Fix `SELECT INTO` and `CREATE TABLE AS` to create tables in the default tablespace, not the base directory (Kris Jurka)
- Fix server to use custom DH SSL parameters correctly (Michael Fuhr)
- Improve qsort performance (Dann Corbit)  
Currently this code is only used on Solaris.
- Fix for OS/X Bonjour on x86 systems (Ashley Clark)
- Fix various minor memory leaks
- Fix problem with password prompting on some Win32 systems (Robert Kinberg)
- Improve `pg_dump`'s handling of default values for domains
- Fix `pg_dumpall` to handle identically-named users and groups reasonably (only possible when dumping from a pre-8.1 server) (Tom)  
The user and group will be merged into a single role with `LOGIN` permission. Formerly the merged role wouldn't have `LOGIN` permission, making it unusable as a user.
- Fix `pg_restore -n` to work as documented (Tom)

## E.19. Release 8.1.3

**Release date:** 2006-02-14

This release contains a variety of fixes from 8.1.2, including one very serious security issue.

### E.19.1. Migration to Version 8.1.3

A dump/restore is not required for those running 8.1.X. However, if you are upgrading from a version earlier than 8.1.2, see the release notes for 8.1.2.

### E.19.2. Changes

- Fix bug that allowed any logged-in user to `SET ROLE` to any other database user id (CVE-2006-0553)  
Due to inadequate validity checking, a user could exploit the special case that `SET ROLE` normally uses to restore the previous role setting after an error. This allowed ordinary users to acquire superuser status, for example. The escalation-of-privilege risk exists only in 8.1.0-8.1.2. However, in all releases back to 7.3 there is a related bug in `SET SESSION AUTHORIZATION` that allows unprivileged users to crash the server, if it has been compiled with Asserts enabled (which is not the default). Thanks to Akio Ishida for reporting this problem.
- Fix bug with row visibility logic in self-inserted rows (Tom)

Under rare circumstances a row inserted by the current command could be seen as already valid, when it should not be. Repairs bug created in 8.0.4, 7.4.9, and 7.3.11 releases.

- Fix race condition that could lead to “file already exists” errors during `pg_clog` and `pg_subtrans` file creation (Tom)
- Fix cases that could lead to crashes if a cache-invalidation message arrives at just the wrong time (Tom)
- Properly check `DOMAIN` constraints for `UNKNOWN` parameters in prepared statements (Neil)
- Ensure `ALTER COLUMN TYPE` will process `FOREIGN KEY`, `UNIQUE`, and `PRIMARY KEY` constraints in the proper order (Nakano Yoshihisa)
- Fixes to allow restoring dumps that have cross-schema references to custom operators or operator classes (Tom)
- Allow `pg_restore` to continue properly after a `COPY` failure; formerly it tried to treat the remaining `COPY` data as SQL commands (Stephen Frost)
- Fix `pg_ctl unregister` crash when the data directory is not specified (Magnus)
- Fix `libpq PQprint` HTML tags (Christoph Zwerschke)
- Fix `ecpg` crash on AMD64 and PPC (Neil)
- Allow `SETOF` and `%TYPE` to be used together in function result type declarations
- Recover properly if error occurs during argument passing in PL/python (Neil)
- Fix memory leak in `plperl_return_next` (Neil)
- Fix PL/perl’s handling of locales on Win32 to match the backend (Andrew)
- Various optimizer fixes (Tom)
- Fix crash when `log_min_messages` is set to `DEBUG3` or above in `postgresql.conf` on Win32 (Bruce)
- Fix `pgxs -L` library path specification for Win32, Cygwin, OS X, AIX (Bruce)
- Check that `SID` is enabled while checking for Win32 admin privileges (Magnus)
- Properly reject out-of-range date inputs (Kris Jurka)
- Portability fix for testing presence of `finite` and `isinf` during configure (Tom)
- Improve speed of `COPY IN` via `libpq`, by avoiding a kernel call per data line (Alon Goldshuv)
- Improve speed of `/contrib/tsearch2` index creation (Tom)

## E.20. Release 8.1.2

**Release date:** 2006-01-09

This release contains a variety of fixes from 8.1.1.

## E.20.1. Migration to Version 8.1.2

A dump/restore is not required for those running 8.1.X. However, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the locale or `plperl` issues described below.

## E.20.2. Changes

- Fix Windows code so that postmaster will continue rather than exit if there is no more room in `ShmemBackendArray` (Magnus)

The previous behavior could lead to a denial-of-service situation if too many connection requests arrive close together. This applies *only* to the Windows port.

- Fix bug introduced in 8.0 that could allow `ReadBuffer` to return an already-used page as new, potentially causing loss of recently-committed data (Tom)
- Fix for protocol-level `Describe` messages issued outside a transaction or in a failed transaction (Tom)
- Fix character string comparison for locales that consider different character combinations as equal, such as Hungarian (Tom)

This might require `REINDEX` to fix existing indexes on textual columns.

- Set locale environment variables during postmaster startup to ensure that `plperl` won't change the locale later

This fixes a problem that occurred if the postmaster was started with environment variables specifying a different locale than what `initdb` had been told. Under these conditions, any use of `plperl` was likely to lead to corrupt indexes. You might need `REINDEX` to fix existing indexes on textual columns if this has happened to you.

- Allow more flexible relocation of installation directories (Tom)

Previous releases supported relocation only if all installation directory paths were the same except for the last component.

- Prevent crashes caused by the use of `ISO-8859-5` and `ISO-8859-9` encodings (Tatsuo)
- Fix longstanding bug in `strpos()` and regular expression handling in certain rarely used Asian multi-byte character sets (Tatsuo)
- Fix bug where `COPY CSV` mode considered any `\.` to terminate the copy data

The new code requires `\.` to appear alone on a line, as per documentation.

- Make `COPY CSV` mode quote a literal data value of `\.` to ensure it cannot be interpreted as the end-of-data marker (Bruce)
- Various fixes for functions returning `RECORDS` (Tom)
- Fix processing of `postgresql.conf` so a final line with no newline is processed properly (Tom)
- Fix bug in `/contrib/pgcrypto` `gen_salt`, which caused it not to use all available salt space for MD5 and XDES algorithms (Marko Kreen, Solar Designer)

Salts for Blowfish and standard DES are unaffected.

- Fix autovacuum crash when processing expression indexes

- Fix `/contrib/dblink` to throw an error, rather than crashing, when the number of columns specified is different from what's actually returned by the query (Joe)

## E.21. Release 8.1.1

**Release date:** 2005-12-12

This release contains a variety of fixes from 8.1.0.

### E.21.1. Migration to Version 8.1.1

A dump/restore is not required for those running 8.1.X.

### E.21.2. Changes

- Fix incorrect optimizations of outer-join conditions (Tom)
- Fix problems with wrong reported column names in cases involving sub-selects flattened by the optimizer (Tom)
- Fix update failures in scenarios involving CHECK constraints, toasted columns, *and* indexes (Tom)
- Fix bgwriter problems after recovering from errors (Tom)

The background writer was found to leak buffer pins after write errors. While not fatal in itself, this might lead to mysterious blockages of later VACUUM commands.

- Prevent failure if client sends Bind protocol message when current transaction is already aborted
- `/contrib/tsearch2` and `/contrib/ltree` fixes (Teodor)
- Fix problems with translated error messages in languages that require word reordering, such as Turkish; also problems with unexpected truncation of output strings and wrong display of the smallest possible bigint value (Andrew, Tom)

These problems only appeared on platforms that were using our `port/snprintf.c` code, which includes BSD variants if `--enable-nls` was given, and perhaps others. In addition, a different form of the translated-error-message problem could appear on Windows depending on which version of `libintl` was used.

- Re-allow AM/PM, HH, HH12, and D format specifiers for `to_char(time)` and `to_char(interval)`. (`to_char(interval)` should probably use HH24.) (Bruce)
- AIX, HP/UX, and MSVC compile fixes (Tom, Hiroshi Saito)
- Optimizer improvements (Tom)
- Retry file reads and writes after Windows NO\_SYSTEM\_RESOURCES error (Qingqing Zhou)

- Prevent autovacuum from crashing during ANALYZE of expression index (Alvaro)
- Fix problems with ON COMMIT DELETE ROWS temp tables
- Fix problems when a trigger alters the output of a SELECT DISTINCT query
- Add 8.1.0 release note item on how to migrate invalid UTF-8 byte sequences (Paul Lindner)

## E.22. Release 8.1

**Release date:** 2005-11-08

### E.22.1. Overview

Major changes in this release:

Improve concurrent access to the shared buffer cache (Tom)

Access to the shared buffer cache was identified as a significant scalability problem, particularly on multi-CPU systems. In this release, the way that locking is done in the buffer manager has been overhauled to reduce lock contention and improve scalability. The buffer manager has also been changed to use a “clock sweep” replacement policy.

Allow index scans to use an intermediate in-memory bitmap (Tom)

In previous releases, only a single index could be used to do lookups on a table. With this feature, if a query has `WHERE tab.col1 = 4 and tab.col2 = 9`, and there is no multicolumn index on `col1` and `col2`, but there is an index on `col1` and another on `col2`, it is possible to search both indexes and combine the results in memory, then do heap fetches for only the rows matching both the `col1` and `col2` restrictions. This is very useful in environments that have a lot of unstructured queries where it is impossible to create indexes that match all possible access conditions. Bitmap scans are useful even with a single index, as they reduce the amount of random access needed; a bitmap index scan is efficient for retrieving fairly large fractions of the complete table, whereas plain index scans are not.

Add two-phase commit (Heikki Linnakangas, Alvaro, Tom)

Two-phase commit allows transactions to be “prepared” on several computers, and once all computers have successfully prepared their transactions (none failed), all transactions can be committed. Even if a machine crashes after a prepare, the prepared transaction can be committed after the machine is restarted. New syntax includes `PREPARE TRANSACTION` and `COMMIT/ROLLBACK PREPARED`. A new system view `pg_prepared_xacts` has also been added.

Create a new role system that replaces users and groups (Stephen Frost)

Roles are a combination of users and groups. Like users, they can have login capability, and like groups, a role can have other roles as members. Roles basically remove the distinction between users and groups. For example, a role can:

- Have login capability (optionally)

- Own objects
- Hold access permissions for database objects
- Inherit permissions from other roles it is a member of

Once a user logs into a role, she obtains capabilities of the login role plus any inherited roles, and can use `SET ROLE` to switch to other roles she is a member of. This feature is a generalization of the SQL standard's concept of roles. This change also replaces `pg_shadow` and `pg_group` by new role-capable catalogs `pg_authid` and `pg_auth_members`. The old tables are redefined as read-only views on the new role tables.

Automatically use indexes for `MIN()` and `MAX()` (Tom)

In previous releases, the only way to use an index for `MIN()` or `MAX()` was to rewrite the query as `SELECT col FROM tab ORDER BY col LIMIT 1`. Index usage now happens automatically.

Move `/contrib/pg_autovacuum` into the main server (Alvaro)

Integrating autovacuum into the server allows it to be automatically started and stopped in sync with the database server, and allows autovacuum to be configured from `postgresql.conf`.

Add shared row level locks using `SELECT ... FOR SHARE` (Alvaro)

While PostgreSQL's MVCC locking allows `SELECT` to never be blocked by writers and therefore does not need shared row locks for typical operations, shared locks are useful for applications that require shared row locking. In particular this reduces the locking requirements imposed by referential integrity checks.

Add dependencies on shared objects, specifically roles (Alvaro)

This extension of the dependency mechanism prevents roles from being dropped while there are still database objects they own. Formerly it was possible to accidentally "orphan" objects by deleting their owner. While this could be recovered from, it was messy and unpleasant.

Improve performance for partitioned tables (Simon)

The new `constraint_exclusion` configuration parameter avoids lookups on child tables where constraints indicate that no matching rows exist in the child table.

This allows for a basic type of table partitioning. If child tables store separate key ranges and this is enforced using appropriate `CHECK` constraints, the optimizer will skip child table accesses when the constraint guarantees no matching rows exist in the child table.

## E.22.2. Migration to Version 8.1

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

The 8.0 release announced that the `to_char()` function for intervals would be removed in 8.1. However, since no better API has been suggested, `to_char(interval)` has been enhanced in 8.1 and will remain in the server.

Observe the following incompatibilities:

- `add_missing_from` is now false by default (Neil)

By default, we now generate an error if a table is used in a query without a `FROM` reference. The old behavior is still available, but the parameter must be set to 'true' to obtain it.

It might be necessary to set `add_missing_from` to true in order to load an existing dump file, if the dump contains any views or rules created using the implicit-`FROM` syntax. This should be a one-time annoyance, because PostgreSQL 8.1 will convert such views and rules to standard explicit-`FROM` syntax. Subsequent dumps will therefore not have the problem.

- Cause input of a zero-length string (") for `float4/float8/oid` to throw an error, rather than treating it as a zero (Neil)

This change is consistent with the current handling of zero-length strings for integers. The schedule for this change was announced in 8.0.

- `default_with_oids` is now false by default (Neil)

With this option set to false, user-created tables no longer have an OID column unless `WITH OIDS` is specified in `CREATE TABLE`. Though OIDs have existed in all releases of PostgreSQL, their use is limited because they are only four bytes long and the counter is shared across all installed databases. The preferred way of uniquely identifying rows is via sequences and the `SERIAL` type, which have been supported since PostgreSQL 6.4.

- Add `E''` syntax so eventually ordinary strings can treat backslashes literally (Bruce)

Currently PostgreSQL processes a backslash in a string literal as introducing a special escape sequence, e.g. `\n` or `\010`. While this allows easy entry of special values, it is nonstandard and makes porting of applications from other databases more difficult. For this reason, the PostgreSQL project is planning to remove the special meaning of backslashes in strings. For backward compatibility and for users who want special backslash processing, a new string syntax has been created. This new string syntax is formed by writing an `E` immediately preceding the single quote that starts the string, e.g. `E'hi\n'`. While this release does not change the handling of backslashes in strings, it does add new configuration parameters to help users migrate applications for future releases:

- `standard_conforming_strings` — does this release treat backslashes literally in ordinary strings?
- `escape_string_warning` — warn about backslashes in ordinary (non-E) strings

The `standard_conforming_strings` value is read-only. Applications can retrieve the value to know how backslashes are processed. (Presence of the parameter can also be taken as an indication that `E''` string syntax is supported.) In a future release, `standard_conforming_strings` will be true, meaning backslashes will be treated literally in non-E strings. To prepare for this change, use `E''` strings in places that need special backslash processing, and turn on `escape_string_warning` to find additional strings that need to be converted to use `E''`. Also, use two single-quotes (") to embed a literal single-quote in a string, rather than the PostgreSQL-supported syntax of backslash single-quote (`\'`). The former is standards-conforming and does not require the use of the `E''` string syntax. You can also use the `$$` string syntax, which does not treat backslashes specially.

- Make `REINDEX DATABASE` reindex all indexes in the database (Tom)

Formerly, `REINDEX DATABASE` reindexed only system tables. This new behavior seems more intuitive. A new command `REINDEX SYSTEM` provides the old functionality of reindexing just the system tables.

- Read-only large object descriptors now obey MVCC snapshot semantics

When a large object is opened with `INV_READ` (and not `INV_WRITE`), the data read from the descriptor will now reflect a “snapshot” of the large object’s state at the time of the transaction snapshot in use by the query that called `lo_open()`. To obtain the old behavior of always returning the latest committed data, include `INV_WRITE` in the mode flags for `lo_open()`.

- Add proper dependencies for arguments of sequence functions (Tom)

In previous releases, sequence names passed to `nextval()`, `currval()`, and `setval()` were stored as simple text strings, meaning that renaming or dropping a sequence used in a `DEFAULT` clause made the clause invalid. This release stores all newly-created sequence function arguments as internal OIDs, allowing them to track sequence renaming, and adding dependency information that prevents improper sequence removal. It also makes such `DEFAULT` clauses immune to schema renaming and search path changes.

Some applications might rely on the old behavior of run-time lookup for sequence names. This can still be done by explicitly casting the argument to `text`, for example `nextval('myseq'::text)`.

Pre-8.1 database dumps loaded into 8.1 will use the old text-based representation and therefore will not have the features of OID-stored arguments. However, it is possible to update a database containing text-based `DEFAULT` clauses. First, save this query into a file, such as `fixseq.sql`:

```
SELECT  'ALTER TABLE ' ||
        pg_catalog.quote_ident(n.nspname) || '.' ||
        pg_catalog.quote_ident(c.relname) ||
        ' ALTER COLUMN ' || pg_catalog.quote_ident(a.attname) ||
        ' SET DEFAULT ' ||
        regexp_replace(d.adsrc,
                        $$val\(\('[^']*'\)::text\)::regclass$$,
                        $$val\1$$,
                        'g') ||
        ';'
FROM    pg_namespace n, pg_class c, pg_attribute a, pg_attrdef d
WHERE   n.oid = c.relnamespace AND
        c.oid = a.attrelid AND
        a.attrelid = d.adrelid AND
        a.attnum = d.adnum AND
        d.adsrc ~ $$val\(\('[^']*'\)::text\)::regclass$;
```

Next, run the query against a database to find what adjustments are required, like this for database `db1`:

```
psql -t -f fixseq.sql db1
```

This will show the `ALTER TABLE` commands needed to convert the database to the newer OID-based representation. If the commands look reasonable, run this to update the database:

```
psql -t -f fixseq.sql db1 | psql -e db1
```

This process must be repeated in each database to be updated.

- In `psql`, treat unquoted `\{digit}+` sequences as octal (Bruce)

In previous releases, `\{digit}+` sequences were treated as decimal, and only `\0{digit}+` were treated as octal. This change was made for consistency.

- Remove grammar productions for prefix and postfix `%` and `^` operators (Tom)

These have never been documented and complicated the use of the modulus operator (`%`) with negative numbers.

- Make `&<` and `&>` for polygons consistent with the box "over" operators (Tom)

- `CREATE LANGUAGE` can ignore the provided arguments in favor of information from `pg_pltemplate` (Tom)

A new system catalog `pg_pltemplate` has been defined to carry information about the preferred definitions of procedural languages (such as whether they have validator functions). When an entry exists in this catalog for the language being created, `CREATE LANGUAGE` will ignore all its parameters except the language name and instead use the catalog information. This measure was taken because of increasing problems with obsolete language definitions being loaded by old dump files. As of 8.1, `pg_dump` will dump procedural language definitions as just `CREATE LANGUAGE name`, relying on a template entry to exist at load time. We expect this will be a more future-proof representation.

- Make `pg_cancel_backend(int)` return a boolean rather than an integer (Neil)
- Some users are having problems loading UTF-8 data into 8.1.X. This is because previous versions allowed invalid UTF-8 byte sequences to be entered into the database, and this release properly accepts only valid UTF-8 sequences. One way to correct a dumpfile is to run the command `iconv -c -f UTF-8 -t UTF-8 -o cleanfile.sql dumpfile.sql`. The `-c` option removes invalid character sequences. A diff of the two files will show the sequences that are invalid. `iconv` reads the entire input file into memory so it might be necessary to use `split` to break up the dump into multiple smaller files for processing.

## E.22.3. Additional Changes

Below you will find a detailed account of the additional changes between PostgreSQL 8.1 and the previous major release.

### E.22.3.1. Performance Improvements

- Improve GiST and R-tree index performance (Neil)
- Improve the optimizer, including auto-resizing of hash joins (Tom)
- Overhaul internal API in several areas
- Change WAL record CRCs from 64-bit to 32-bit (Tom)

We determined that the extra cost of computing 64-bit CRCs was significant, and the gain in reliability too marginal to justify it.

- Prevent writing large empty gaps in WAL pages (Tom)
- Improve spinlock behavior on SMP machines, particularly Opteron (Tom)
- Allow nonconsecutive index columns to be used in a multicolumn index (Tom)

For example, this allows an index on columns `a,b,c` to be used in a query with `WHERE a = 4 and c = 10`.

- Skip WAL logging for `CREATE TABLE AS / SELECT INTO` (Simon)

Since a crash during `CREATE TABLE AS` would cause the table to be dropped during recovery, there is no reason to WAL log as the table is loaded. (Logging still happens if WAL archiving is enabled, however.)

- Allow concurrent GiST index access (Teodor, Oleg)
- Add configuration parameter `full_page_writes` to control writing full pages to WAL (Bruce)  
To prevent partial disk writes from corrupting the database, PostgreSQL writes a complete copy of each database disk page to WAL the first time it is modified after a checkpoint. This option turns off that functionality for more speed. This is safe to use with battery-backed disk caches where partial page writes cannot happen.
- Use `O_DIRECT` if available when using `O_SYNC` for `wal_sync_method` (Itagaki Takahiro)  
`O_DIRECT` causes disk writes to bypass the kernel cache, and for WAL writes, this improves performance.
- Improve `COPY FROM` performance (Alon Goldshuv)  
This was accomplished by reading `COPY` input in larger chunks, rather than character by character.
- Improve the performance of `COUNT()`, `SUM()`, `AVG()`, `STDDEV()`, and `VARIANCE()` (Neil, Tom)

### E.22.3.2. Server Changes

- Prevent problems due to transaction ID (XID) wraparound (Tom)  
The server will now warn when the transaction counter approaches the wraparound point. If the counter becomes too close to wraparound, the server will stop accepting queries. This ensures that data is not lost before needed vacuuming is performed.
- Fix problems with object IDs (OIDs) conflicting with existing system objects after the OID counter has wrapped around (Tom)
- Add warning about the need to increase `max_fsm_relations` and `max_fsm_pages` during `VACUUM` (Ron Mayer)
- Add `temp_buffers` configuration parameter to allow users to determine the size of the local buffer area for temporary table access (Tom)
- Add session start time and client IP address to `pg_stat_activity` (Magnus)
- Adjust `pg_stat` views for bitmap scans (Tom)  
The meanings of some of the fields have changed slightly.
- Enhance `pg_locks` view (Tom)
- Log queries for client-side `PREPARE` and `EXECUTE` (Simon)
- Allow Kerberos name and user name case sensitivity to be specified in `postgresql.conf` (Magnus)
- Add configuration parameter `krb_server_hostname` so that the server host name can be specified as part of service principal (Todd Kover)  
If not set, any service principal matching an entry in the keytab can be used. This is new Kerberos matching behavior in this release.
- Add `log_line_prefix` options for millisecond timestamps (`%m`) and remote host (`%h`) (Ed L.)
- Add WAL logging for GiST indexes (Teodor, Oleg)  
GiST indexes are now safe for crash and point-in-time recovery.

- Remove old \*.backup files when we do `pg_stop_backup()` (Bruce)  
This prevents a large number of \*.backup files from existing in `pg_xlog/`.
- Add configuration parameters to control TCP/IP keep-alive times for idle, interval, and count (Oliver Jowett)  
These values can be changed to allow more rapid detection of lost client connections.
- Add per-user and per-database connection limits (Petr Jelinek)  
Using `ALTER USER` and `ALTER DATABASE`, limits can now be enforced on the maximum number of sessions that can concurrently connect as a specific user or to a specific database. Setting the limit to zero disables user or database connections.
- Allow more than two gigabytes of shared memory and per-backend work memory on 64-bit machines (Koichi Suzuki)
- New system catalog `pg_pltemplate` allows overriding obsolete procedural-language definitions in dump files (Tom)

### E.22.3.3. Query Changes

- Add temporary views (Koju Iijima, Neil)
- Fix `HAVING` without any aggregate functions or `GROUP BY` so that the query returns a single group (Tom)  
Previously, such a case would treat the `HAVING` clause the same as a `WHERE` clause. This was not per spec.
- Add `USING` clause to allow additional tables to be specified to `DELETE` (Euler Taveira de Oliveira, Neil)  
In prior releases, there was no clear method for specifying additional tables to be used for joins in a `DELETE` statement. `UPDATE` already has a `FROM` clause for this purpose.
- Add support for `\x` hex escapes in backend and `ecpg` strings (Bruce)  
This is just like the standard C `\x` escape syntax. Octal escapes were already supported.
- Add `BETWEEN SYMMETRIC` query syntax (Pavel Stehule)  
This feature allows `BETWEEN` comparisons without requiring the first value to be less than the second. For example, `2 BETWEEN [ASYMMETRIC] 3 AND 1` returns false, while `2 BETWEEN SYMMETRIC 3 AND 1` returns true. `BETWEEN ASYMMETRIC` was already supported.
- Add `NOWAIT` option to `SELECT ... FOR UPDATE/SHARE` (Hans-Juergen Schoenig)  
While the `statement_timeout` configuration parameter allows a query taking more than a certain amount of time to be cancelled, the `NOWAIT` option allows a query to be canceled as soon as a `SELECT ... FOR UPDATE/SHARE` command cannot immediately acquire a row lock.

### E.22.3.4. Object Manipulation Changes

- Track dependencies of shared objects (Alvaro)

PostgreSQL allows global tables (users, databases, tablespaces) to reference information in multiple databases. This addition adds dependency information for global tables, so, for example, user ownership can be tracked across databases, so a user who owns something in any database can no longer be removed. Dependency tracking already existed for database-local objects.

- Allow limited `ALTER OWNER` commands to be performed by the object owner (Stephen Frost)

Prior releases allowed only superusers to change object owners. Now, ownership can be transferred if the user executing the command owns the object and would be able to create it as the new owner (that is, the user is a member of the new owning role and that role has the `CREATE` permission that would be needed to create the object afresh).

- Add `ALTER object SET SCHEMA` capability for some object types (tables, functions, types) (Bernd Helmle)

This allows objects to be moved to different schemas.

- Add `ALTER TABLE ENABLE/DISABLE TRIGGER` to disable triggers (Satoshi Nagayasu)

### E.22.3.5. Utility Command Changes

- Allow `TRUNCATE` to truncate multiple tables in a single command (Alvaro)

Because of referential integrity checks, it is not allowed to truncate a table that is part of a referential integrity constraint. Using this new functionality, `TRUNCATE` can be used to truncate such tables, if both tables involved in a referential integrity constraint are truncated in a single `TRUNCATE` command.

- Properly process carriage returns and line feeds in `COPY CSV` mode (Andrew)

In release 8.0, carriage returns and line feeds in `CSV COPY TO` were processed in an inconsistent manner. (This was documented on the TODO list.)

- Add `COPY WITH CSV HEADER` to allow a header line as the first line in `COPY` (Andrew)

This allows handling of the common `CSV` usage of placing the column names on the first line of the data file. For `COPY TO`, the first line contains the column names, and for `COPY FROM`, the first line is ignored.

- On Windows, display better sub-second precision in `EXPLAIN ANALYZE` (Magnus)

- Add trigger duration display to `EXPLAIN ANALYZE` (Tom)

Prior releases included trigger execution time as part of the total execution time, but did not show it separately. It is now possible to see how much time is spent in each trigger.

- Add support for `\x` hex escapes in `COPY` (Sergey Ten)

Previous releases only supported octal escapes.

- Make `SHOW ALL` include variable descriptions (Matthias Schmidt)

`SHOW varname` still only displays the variable's value and does not include the description.

- Make `initdb` create a new standard database called `postgres`, and convert utilities to use `postgres` rather than `template1` for standard lookups (Dave)

In prior releases, `template1` was used both as a default connection for utilities like `createuser`, and as a template for new databases. This caused `CREATE DATABASE` to sometimes fail, because a new database

cannot be created if anyone else is in the template database. With this change, the default connection database is now `postgres`, meaning it is much less likely someone will be using `template1` during `CREATE DATABASE`.

- Create new `reindexdb` command-line utility by moving `/contrib/reindexdb` into the server (Euler Taveira de Oliveira)

### E.22.3.6. Data Type and Function Changes

- Add `MAX()` and `MIN()` aggregates for array types (Koji Iijima)
- Fix `to_date()` and `to_timestamp()` to behave reasonably when `CC` and `YY` fields are both used (Karel Zak)

If the format specification contains `CC` and a year specification is `YYY` or longer, ignore the `CC`. If the year specification is `YY` or shorter, interpret `CC` as the previous century.

- Add `md5(bytea)` (Abhijit Menon-Sen)

`md5(text)` already existed.

- Add support for `numeric ^ numeric` based on `power(numeric, numeric)`

The function already existed, but there was no operator assigned to it.

- Fix `NUMERIC` modulus by properly truncating the quotient during computation (Bruce)

In previous releases, modulus for large values sometimes returned negative results due to rounding of the quotient.

- Add a function `lastval()` (Dennis Björklund)

`lastval()` is a simplified version of `currval()`. It automatically determines the proper sequence name based on the most recent `nextval()` or `setval()` call performed by the current session.

- Add `to_timestamp(DOUBLE PRECISION)` (Michael Glaesemann)

Converts Unix seconds since 1970 to a `TIMESTAMP WITH TIMEZONE`.

- Add `pg_postmaster_start_time()` function (Euler Taveira de Oliveira, Matthias Schmidt)
- Allow the full use of time zone names in `AT TIME ZONE`, not just the short list previously available (Magnus)

Previously, only a predefined list of time zone names were supported by `AT TIME ZONE`. Now any supported time zone name can be used, e.g.:

```
SELECT CURRENT_TIMESTAMP AT TIME ZONE 'Europe/London';
```

In the above query, the time zone used is adjusted based on the daylight saving time rules that were in effect on the supplied date.

- Add `GREATEST()` and `LEAST()` variadic functions (Pavel Stehule)

These functions take a variable number of arguments and return the greatest or least value among the arguments.

- Add `pg_column_size()` (Mark Kirkwood)

This returns storage size of a column, which might be compressed.

- Add `regexp_replace()` (Atsushi Ogawa)

This allows regular expression replacement, like `sed`. An optional flag argument allows selection of global (replace all) and case-insensitive modes.

- Fix interval division and multiplication (Bruce)

Previous versions sometimes returned unjustified results, like `'4 months'::interval / 5` returning `'1 mon -6 days'`.

- Fix roundoff behavior in timestamp, time, and interval output (Tom)

This fixes some cases in which the seconds field would be shown as 60 instead of incrementing the higher-order fields.

- Add a separate day field to type `interval` so a one day interval can be distinguished from a 24 hour interval (Michael Glaesemann)

Days that contain a daylight saving time adjustment are not 24 hours long, but typically 23 or 25 hours. This change creates a conceptual distinction between intervals of “so many days” and intervals of “so many hours”. Adding `1 day` to a timestamp now gives the same local time on the next day even if a daylight saving time adjustment occurs between, whereas adding `24 hours` will give a different local time when this happens. For example, under US DST rules:

```
'2005-04-03 00:00:00-05' + '1 day' = '2005-04-04 00:00:00-04'
'2005-04-03 00:00:00-05' + '24 hours' = '2005-04-04 01:00:00-04'
```

- Add `justify_days()` and `justify_hours()` (Michael Glaesemann)

These functions, respectively, adjust days to an appropriate number of full months and days, and adjust hours to an appropriate number of full days and hours.

- Move `/contrib/dbsize` into the backend, and rename some of the functions (Dave Page, Andreas Pflug)

- `pg_tablespace_size()`
- `pg_database_size()`
- `pg_relation_size()`
- `pg_total_relation_size()`
- `pg_size_pretty()`

`pg_total_relation_size()` includes indexes and TOAST tables.

- Add functions for read-only file access to the cluster directory (Dave Page, Andreas Pflug)

- `pg_stat_file()`
- `pg_read_file()`
- `pg_ls_dir()`

- Add `pg_reload_conf()` to force reloading of the configuration files (Dave Page, Andreas Pflug)

- Add `pg_rotate_logfile()` to force rotation of the server log file (Dave Page, Andreas Pflug)
- Change `pg_stat_*` views to include TOAST tables (Tom)

### E.22.3.7. Encoding and Locale Changes

- Rename some encodings to be more consistent and to follow international standards (Bruce)
  - `UNICODE` is now `UTF8`
  - `ALT` is now `WIN866`
  - `WIN` is now `WIN1251`
  - `TCVN` is now `WIN1258`

The original names still work.

- Add support for `WIN1252` encoding (Roland Volkmann)
- Add support for four-byte `UTF8` characters (John Hansen)

Previously only one, two, and three-byte `UTF8` characters were supported. This is particularly important for support for some Chinese character sets.

- Allow direct conversion between `EUC_JP` and `SJIS` to improve performance (Atsushi Ogawa)
- Allow the `UTF8` encoding to work on Windows (Magnus)

This is done by mapping `UTF8` to the Windows-native `UTF16` implementation.

### E.22.3.8. General Server-Side Language Changes

- Fix `ALTER LANGUAGE RENAME` (Sergey Yatskevich)
- Allow function characteristics, like strictness and volatility, to be modified via `ALTER FUNCTION` (Neil)
- Increase the maximum number of function arguments to 100 (Tom)
- Allow SQL and PL/PgSQL functions to use `OUT` and `INOUT` parameters (Tom)

`OUT` is an alternate way for a function to return values. Instead of using `RETURN`, values can be returned by assigning to parameters declared as `OUT` or `INOUT`. This is notationally simpler in some cases, particularly so when multiple values need to be returned. While returning multiple values from a function was possible in previous releases, this greatly simplifies the process. (The feature will be extended to other server-side languages in future releases.)

- Move language handler functions into the `pg_catalog` schema

This makes it easier to drop the public schema if desired.

- Add `SPI_getnsname()` to `SPI` (Neil)

### E.22.3.9. PL/PgSQL Server-Side Language Changes

- Overhaul the memory management of PL/PgSQL functions (Neil)  
The parsetree of each function is now stored in a separate memory context. This allows this memory to be easily reclaimed when it is no longer needed.
- Check function syntax at `CREATE FUNCTION` time, rather than at runtime (Neil)  
Previously, most syntax errors were reported only when the function was executed.
- Allow `OPEN` to open non-`SELECT` queries like `EXPLAIN` and `SHOW` (Tom)
- No longer require functions to issue a `RETURN` statement (Tom)  
This is a byproduct of the newly added `OUT` and `INOUT` functionality. `RETURN` can be omitted when it is not needed to provide the function's return value.
- Add support for an optional `INTO` clause to PL/PgSQL's `EXECUTE` statement (Pavel Stehule, Neil)
- Make `CREATE TABLE AS` set `ROW_COUNT` (Tom)
- Define `SQLSTATE` and `SQLERRM` to return the `SQLSTATE` and error message of the current exception (Pavel Stehule, Neil)  
These variables are only defined inside exception blocks.
- Allow the parameters to the `RAISE` statement to be expressions (Pavel Stehule, Neil)
- Add a loop `CONTINUE` statement (Pavel Stehule, Neil)
- Allow block and loop labels (Pavel Stehule)

### E.22.3.10. PL/Perl Server-Side Language Changes

- Allow large result sets to be returned efficiently (Abhijit Menon-Sen)  
This allows functions to use `return_next()` to avoid building the entire result set in memory.
- Allow one-row-at-a-time retrieval of query results (Abhijit Menon-Sen)  
This allows functions to use `spi_query()` and `spi_fetchrow()` to avoid accumulating the entire result set in memory.
- Force PL/Perl to handle strings as `UTF8` if the server encoding is `UTF8` (David Kamholz)
- Add a validator function for PL/Perl (Andrew)  
This allows syntax errors to be reported at definition time, rather than execution time.
- Allow PL/Perl to return a Perl array when the function returns an array type (Andrew)  
This basically maps PostgreSQL arrays to Perl arrays.
- Allow Perl nonfatal warnings to generate `NOTICE` messages (Andrew)
- Allow Perl's `strict` mode to be enabled (Andrew)

### E.22.3.11. psql Changes

- Add `\set ON_ERROR_ROLLBACK` to allow statements in a transaction to error without affecting the rest of the transaction (Greg Sabino Mullane)

This is basically implemented by wrapping every statement in a sub-transaction.

- Add support for `\x` hex strings in psql variables (Bruce)

Octal escapes were already supported.

- Add support for `troff -ms` output format (Roger Leigh)
- Allow the history file location to be controlled by `HISTFILE` (Andreas Seltenreich)

This allows configuration of per-database history storage.

- Prevent `\x` (expanded mode) from affecting the output of `\d tablename` (Neil)
- Add `-L` option to psql to log sessions (Lorne Sunley)

This option was added because some operating systems do not have simple command-line activity logging functionality.

- Make `\d` show the tablespaces of indexes (Qingqing Zhou)
  - Allow psql help (`\h`) to make a best guess on the proper help information (Greg Sabino Mullane)
- This allows the user to just add `\h` to the front of the syntax error query and get help on the supported syntax. Previously any additional query text beyond the command name had to be removed to use `\h`.

- Add `\pset numericlocale` to allow numbers to be output in a locale-aware format (Eugen Nedelcu)
- For example, using `C` locale `100000` would be output as `100,000.0` while a European locale might output this value as `100.000,0`.

- Make startup banner show both server version number and psql's version number, when they are different (Bruce)

Also, a warning will be shown if the server and psql are from different major releases.

### E.22.3.12. pg\_dump Changes

- Add `-n / --schema` switch to `pg_restore` (Richard van den Berg)

This allows just the objects in a specified schema to be restored.

- Allow `pg_dump` to dump large objects even in text mode (Tom)

With this change, large objects are now always dumped; the former `-b` switch is a no-op.

- Allow `pg_dump` to dump a consistent snapshot of large objects (Tom)
- Dump comments for large objects (Tom)
- Add `--encoding` to `pg_dump` (Magnus Hagander)

This allows a database to be dumped in an encoding that is different from the server's encoding. This is valuable when transferring the dump to a machine with a different encoding.

- Rely on `pg_pltemplate` for procedural languages (Tom)

If the call handler for a procedural language is in the `pg_catalog` schema, `pg_dump` does not dump the handler. Instead, it dumps the language using just `CREATE LANGUAGE name`, relying on the `pg_pltemplate` catalog to provide the language's creation parameters at load time.

### E.22.3.13. libpq Changes

- Add a `PGPASSFILE` environment variable to specify the password file's filename (Andrew)
- Add `lo_create()`, that is similar to `lo_creat()` but allows the OID of the large object to be specified (Tom)
- Make libpq consistently return an error to the client application on `malloc()` failure (Neil)

### E.22.3.14. Source Code Changes

- Fix `pgxs` to support building against a relocated installation
- Add spinlock support for the Itanium processor using Intel compiler (Vikram Kalsi)
- Add Kerberos 5 support for Windows (Magnus)
- Add Chinese FAQ ([laser@pgsqldb.com](mailto:laser@pgsqldb.com))
- Rename `Rendezvous` to `Bonjour` to match OS/X feature renaming (Bruce)
- Add support for `fsync_writethrough` on Darwin (Chris Campbell)
- Streamline the passing of information within the server, the optimizer, and the lock system (Tom)
- Allow `pg_config` to be compiled using MSVC (Andrew)

This is required to build `DBD::Pg` using MSVC.

- Remove support for Kerberos V4 (Magnus)  
Kerberos 4 had security vulnerabilities and is no longer maintained.
- Code cleanups (Coverity static analysis performed by EnterpriseDB)
- Modify `postgresql.conf` to use documentation defaults `on/off` rather than `true/false` (Bruce)
- Enhance `pg_config` to be able to report more build-time values (Tom)
- Allow libpq to be built thread-safe on Windows (Dave Page)
- Allow IPv6 connections to be used on Windows (Andrew)
- Add Server Administration documentation about I/O subsystem reliability (Bruce)
- Move private declarations from `gist.h` to `gist_private.h` (Neil)

In previous releases, `gist.h` contained both the public GiST API (intended for use by authors of GiST index implementations) as well as some private declarations used by the implementation of GiST itself. The latter have been moved to a separate file, `gist_private.h`. Most GiST index implementations should be unaffected.

- Overhaul GiST memory management (Neil)

GiST methods are now always invoked in a short-lived memory context. Therefore, memory allocated via `palloc()` will be reclaimed automatically, so GiST index implementations do not need to manually release allocated memory via `pfree()`.

### E.22.3.15. Contrib Changes

- Add `/contrib/pg_buffercache` contrib module (Mark Kirkwood)

This displays the contents of the buffer cache, for debugging and performance tuning purposes.

- Remove `/contrib/array` because it is obsolete (Tom)
- Clean up the `/contrib/lo` module (Tom)
- Move `/contrib/findoidjoins` to `/src/tools` (Tom)
- Remove the `<<`, `>>`, `&<`, and `&>` operators from `/contrib/cube`

These operators were not useful.

- Improve `/contrib/btree_gist` (Janko Richter)
- Improve `/contrib/pgbench` (Tomoaki Sato, Tatsuo)

There is now a facility for testing with SQL command scripts given by the user, instead of only a hard-wired command sequence.

- Improve `/contrib/pgcrypto` (Marko Kreen)
  - Implementation of OpenPGP symmetric-key and public-key encryption
- Stand alone build: include SHA256/384/512 hashes, Fortuna PRNG
- OpenSSL build: support 3DES, use internal AES with OpenSSL < 0.9.7
- Take build parameters (OpenSSL, zlib) from `configure` result

There is no need to edit the `Makefile` anymore.

- Remove support for `libmhash` and `libmcrypt`

## E.23. Release 8.0.15

**Release date:** 2008-01-07

This release contains a variety of fixes from 8.0.14, including fixes for significant security issues.

This is the last 8.0.X release for which the PostgreSQL community will produce binary packages for Windows. Windows users are encouraged to move to 8.2.X or later, since there are Windows-specific fixes in 8.2.X that are impractical to back-port. 8.0.X will continue to be supported on other platforms.

## E.23.1. Migration to Version 8.0.15

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

## E.23.2. Changes

- Prevent functions in indexes from executing with the privileges of the user running `VACUUM`, `ANALYZE`, etc (Tom)

Functions used in index expressions and partial-index predicates are evaluated whenever a new table entry is made. It has long been understood that this poses a risk of trojan-horse code execution if one modifies a table owned by an untrustworthy user. (Note that triggers, defaults, check constraints, etc. pose the same type of risk.) But functions in indexes pose extra danger because they will be executed by routine maintenance operations such as `VACUUM FULL`, which are commonly performed automatically under a superuser account. For example, a nefarious user can execute code with superuser privileges by setting up a trojan-horse index definition and waiting for the next routine vacuum. The fix arranges for standard maintenance operations (including `VACUUM`, `ANALYZE`, `REINDEX`, and `CLUSTER`) to execute as the table owner rather than the calling user, using the same privilege-switching mechanism already used for `SECURITY DEFINER` functions. To prevent bypassing this security measure, execution of `SET SESSION AUTHORIZATION` and `SET ROLE` is now forbidden within a `SECURITY DEFINER` context. (CVE-2007-6600)

- Repair assorted bugs in the regular-expression package (Tom, Will Drewry)

Suitably crafted regular-expression patterns could cause crashes, infinite or near-infinite looping, and/or massive memory consumption, all of which pose denial-of-service hazards for applications that accept regex search patterns from untrustworthy sources. (CVE-2007-4769, CVE-2007-4772, CVE-2007-6067)

- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

The fix that appeared for this in 8.0.14 was incomplete, as it plugged the hole for only some `dblink` functions. (CVE-2007-6601, CVE-2007-3278)

- Update time zone data files to tzdata release 2007k (in particular, recent Argentina changes) (Tom)
- Fix planner failure in some cases of `WHERE false AND var IN (SELECT ...)` (Tom)
- Preserve the tablespace of indexes that are rebuilt by `ALTER TABLE ... ALTER COLUMN TYPE` (Tom)
- Make archive recovery always start a new WAL timeline, rather than only when a recovery stop time was used (Simon)

This avoids a corner-case risk of trying to overwrite an existing archived copy of the last WAL segment, and seems simpler and cleaner than the original definition.

- Make `VACUUM` not use all of `maintenance_work_mem` when the table is too small for it to be useful (Alvaro)
- Fix potential crash in `translate()` when using a multibyte database encoding (Tom)
- Fix PL/Perl to cope when platform's Perl defines type `bool` as `int` rather than `char` (Tom)

While this could theoretically happen anywhere, no standard build of Perl did things this way ... until Mac OS X 10.5.

- Fix PL/Python to not crash on long exception messages (Alvaro)
- Fix `pg_dump` to correctly handle inheritance child tables that have default expressions different from their parent's (Tom)
- `ecpg` parser fixes (Michael)
- Make `contrib/tablefunc`'s `crosstab()` handle NULL rowid as a category in its own right, rather than crashing (Joe)
- Fix `tsvector` and `tsquery` output routines to escape backslashes correctly (Teodor, Bruce)
- Fix crash of `to_tsvector()` on huge input strings (Teodor)
- Require a specific version of Autoconf to be used when re-generating the `configure` script (Peter)

This affects developers and packagers only. The change was made to prevent accidental use of untested combinations of Autoconf and PostgreSQL versions. You can remove the version check if you really want to use a different Autoconf version, but it's your responsibility whether the result works or not.

## E.24. Release 8.0.14

**Release date:** 2007-09-17

This release contains a variety of fixes from 8.0.13.

### E.24.1. Migration to Version 8.0.14

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.24.2. Changes

- Prevent index corruption when a transaction inserts rows and then aborts close to the end of a concurrent `VACUUM` on the same table (Tom)

- Make `CREATE DOMAIN ... DEFAULT NULL` work properly (Tom)
- Fix excessive logging of SSL error messages (Tom)
- Fix logging so that log messages are never interleaved when using the syslogger process (Andrew)
- Fix crash when `log_min_error_statement` logging runs out of memory (Tom)
- Fix incorrect handling of some foreign-key corner cases (Tom)
- Prevent `CLUSTER` from failing due to attempting to process temporary tables of other sessions (Alvaro)
- Update the time zone database rules, particularly New Zealand's upcoming changes (Tom)
- Windows socket improvements (Magnus)
- Suppress timezone name (%Z) in log timestamps on Windows because of possible encoding mismatches (Tom)
- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

## E.25. Release 8.0.13

**Release date:** 2007-04-23

This release contains a variety of fixes from 8.0.12, including a security fix.

### E.25.1. Migration to Version 8.0.13

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.25.2. Changes

- Support explicit placement of the temporary-table schema within `search_path`, and disable searching it for functions and operators (Tom)

This is needed to allow a security-definer function to set a truly secure value of `search_path`. Without it, an unprivileged SQL user can use temporary objects to execute code with the privileges of the security-definer function (CVE-2007-2138). See `CREATE FUNCTION` for more information.

- `/contrib/tsearch2` crash fixes (Teodor)
- Fix potential-data-corruption bug in how `VACUUM FULL` handles `UPDATE` chains (Tom, Pavan Deolasee)
- Fix PANIC during enlargement of a hash index (bug introduced in 8.0.10) (Tom)
- Fix POSIX-style timezone specs to follow new USA DST rules (Tom)

## E.26. Release 8.0.12

**Release date:** 2007-02-07

This release contains one fix from 8.0.11.

### E.26.1. Migration to Version 8.0.12

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.26.2. Changes

- Remove overly-restrictive check for type length in constraints and functional indexes(Tom)

## E.27. Release 8.0.11

**Release date:** 2007-02-05

This release contains a variety of fixes from 8.0.10, including a security fix.

### E.27.1. Migration to Version 8.0.11

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.27.2. Changes

- Remove security vulnerabilities that allowed connected users to read backend memory (Tom)

The vulnerabilities involve suppressing the normal check that a SQL function returns the data type it's declared to, and changing the data type of a table column (CVE-2007-0555, CVE-2007-0556). These errors can easily be exploited to cause a backend crash, and in principle might be used to read database content that the user should not be able to access.

- Fix rare bug wherein btree index page splits could fail due to choosing an infeasible split point (Heikki Linnakangas)

- Fix for rare `Assert()` crash triggered by `UNION` (Tom)
- Tighten security of multi-byte character processing for UTF8 sequences over three bytes long (Tom)

## E.28. Release 8.0.10

**Release date:** 2007-01-08

This release contains a variety of fixes from 8.0.9.

### E.28.1. Migration to Version 8.0.10

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.28.2. Changes

- Improve handling of `getaddrinfo()` on AIX (Tom)  
This fixes a problem with starting the statistics collector, among other things.
- Fix “failed to re-find parent key” errors in `VACUUM` (Tom)
- Fix race condition for truncation of a large relation across a gigabyte boundary by `VACUUM` (Tom)
- Fix bugs affecting multi-gigabyte hash indexes (Tom)
- Fix possible deadlock in Windows signal handling (Teodor)
- Fix error when constructing an `ARRAY[]` made up of multiple empty elements (Tom)
- Fix `ecpg` memory leak during connection (Michael)
- `to_number()` and `to_char(numeric)` are now `STABLE`, not `IMMUTABLE`, for new `initdb` installs (Tom)

This is because `lc_numeric` can potentially change the output of these functions.

- Improve index usage of regular expressions that use parentheses (Tom)  
This improves `psql \d` performance also.
- Update timezone database

This affects Australian and Canadian daylight-savings rules in particular.

## E.29. Release 8.0.9

**Release date:** 2006-10-16

This release contains a variety of fixes from 8.0.8.

### E.29.1. Migration to Version 8.0.9

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.29.2. Changes

- Fix crash when referencing `NEW` row values in rule `WHERE` expressions (Tom)
- Fix core dump when an untyped literal is taken as `ANYARRAY`
- Fix mishandling of `AFTER` triggers when query contains a `SQL` function returning multiple rows (Tom)
- Fix `ALTER TABLE ... TYPE` to recheck `NOT NULL` for `USING` clause (Tom)
- Fix `string_to_array()` to handle overlapping matches for the separator string  
For example, `string_to_array('123xx456xxx789', 'xx')`.
- Fix corner cases in pattern matching for `psql`'s `\d` commands
- Fix index-corrupting bugs in `/contrib/ltree` (Teodor)
- Numerous robustness fixes in `ecpg` (Joachim Wieland)
- Fix backslash escaping in `/contrib/dbmirror`
- Fix instability of statistics collection on Win32 (Tom, Andrew)
- Fixes for AIX and Intel compilers (Tom)

## E.30. Release 8.0.8

**Release date:** 2006-05-23

This release contains a variety of fixes from 8.0.7, including patches for extremely serious security issues.

## E.30.1. Migration to Version 8.0.8

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

Full security against the SQL-injection attacks described in CVE-2006-2313 and CVE-2006-2314 might require changes in application code. If you have applications that embed untrustworthy strings into SQL commands, you should examine them as soon as possible to ensure that they are using recommended escaping techniques. In most cases, applications should be using subroutines provided by libraries or drivers (such as libpq's `PQescapeStringConn()`) to perform string escaping, rather than relying on *ad hoc* code to do it.

## E.30.2. Changes

- Change the server to reject invalidly-encoded multibyte characters in all cases (Tatsuo, Tom)

While PostgreSQL has been moving in this direction for some time, the checks are now applied uniformly to all encodings and all textual input, and are now always errors not merely warnings. This change defends against SQL-injection attacks of the type described in CVE-2006-2313.

- Reject unsafe uses of `\'` in string literals

As a server-side defense against SQL-injection attacks of the type described in CVE-2006-2314, the server now only accepts `"` and not `\'` as a representation of ASCII single quote in SQL string literals. By default, `\'` is rejected only when `client_encoding` is set to a client-only encoding (SJIS, BIG5, GBK, GB18030, or UHC), which is the scenario in which SQL injection is possible. A new configuration parameter `backslash_quote` is available to adjust this behavior when needed. Note that full security against CVE-2006-2314 might require client-side changes; the purpose of `backslash_quote` is in part to make it obvious that insecure clients are insecure.

- Modify libpq's string-escaping routines to be aware of encoding considerations and `standard_conforming_strings`

This fixes libpq-using applications for the security issues described in CVE-2006-2313 and CVE-2006-2314, and also future-proofs them against the planned changeover to SQL-standard string literal syntax. Applications that use multiple PostgreSQL connections concurrently should migrate to `PQescapeStringConn()` and `PQescapeByteaConn()` to ensure that escaping is done correctly for the settings in use in each database connection. Applications that do string escaping “by hand” should be modified to rely on library routines instead.

- Fix some incorrect encoding conversion functions

`win1251_to_iso`, `alt_to_iso`, `euc_tw_to_big5`, `euc_tw_to_mic`, `mic_to_euc_tw` were all broken to varying extents.

- Clean up stray remaining uses of `\'` in strings (Bruce, Jan)
- Fix bug that sometimes caused OR'd index scans to miss rows they should have returned
- Fix WAL replay for case where a btree index has been truncated
- Fix `SIMILAR TO` for patterns involving `|` (Tom)

- Fix `SELECT INTO` and `CREATE TABLE AS` to create tables in the default tablespace, not the base directory (Kris Jurka)
- Fix server to use custom DH SSL parameters correctly (Michael Fuhr)
- Fix for Bonjour on Intel Macs (Ashley Clark)
- Fix various minor memory leaks
- Fix problem with password prompting on some Win32 systems (Robert Kinberg)

## E.31. Release 8.0.7

**Release date:** 2006-02-14

This release contains a variety of fixes from 8.0.6.

### E.31.1. Migration to Version 8.0.7

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.6, see the release notes for 8.0.6.

### E.31.2. Changes

- Fix potential crash in `SET SESSION AUTHORIZATION` (CVE-2006-0553)

An unprivileged user could crash the server process, resulting in momentary denial of service to other users, if the server has been compiled with Asserts enabled (which is not the default). Thanks to Akio Ishida for reporting this problem.

- Fix bug with row visibility logic in self-inserted rows (Tom)

Under rare circumstances a row inserted by the current command could be seen as already valid, when it should not be. Repairs bug created in 8.0.4, 7.4.9, and 7.3.11 releases.

- Fix race condition that could lead to “file already exists” errors during `pg_clog` and `pg_subtrans` file creation (Tom)
- Fix cases that could lead to crashes if a cache-invalidation message arrives at just the wrong time (Tom)
- Properly check `DOMAIN` constraints for `UNKNOWN` parameters in prepared statements (Neil)
- Ensure `ALTER COLUMN TYPE` will process `FOREIGN KEY`, `UNIQUE`, and `PRIMARY KEY` constraints in the proper order (Nakano Yoshihisa)
- Fixes to allow restoring dumps that have cross-schema references to custom operators or operator classes (Tom)

- Allow `pg_restore` to continue properly after a `COPY` failure; formerly it tried to treat the remaining `COPY` data as SQL commands (Stephen Frost)
- Fix `pg_ctl unregister` crash when the data directory is not specified (Magnus)
- Fix `ecpg` crash on AMD64 and PPC (Neil)
- Recover properly if error occurs during argument passing in PL/python (Neil)
- Fix PL/perl's handling of locales on Win32 to match the backend (Andrew)
- Fix crash when `log_min_messages` is set to `DEBUG3` or above in `postgresql.conf` on Win32 (Bruce)
- Fix `pgxs -L` library path specification for Win32, Cygwin, OS X, AIX (Bruce)
- Check that SID is enabled while checking for Win32 admin privileges (Magnus)
- Properly reject out-of-range date inputs (Kris Jurka)
- Portability fix for testing presence of `finite` and `isinf` during configure (Tom)

## E.32. Release 8.0.6

**Release date:** 2006-01-09

This release contains a variety of fixes from 8.0.5.

### E.32.1. Migration to Version 8.0.6

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.3, see the release notes for 8.0.3. Also, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the locale or plperl issues described below.

### E.32.2. Changes

- Fix Windows code so that postmaster will continue rather than exit if there is no more room in `ShmemBackendArray` (Magnus)

The previous behavior could lead to a denial-of-service situation if too many connection requests arrive close together. This applies *only* to the Windows port.

- Fix bug introduced in 8.0 that could allow `ReadBuffer` to return an already-used page as new, potentially causing loss of recently-committed data (Tom)
- Fix for protocol-level Describe messages issued outside a transaction or in a failed transaction (Tom)
- Fix character string comparison for locales that consider different character combinations as equal, such as Hungarian (Tom)

This might require `REINDEX` to fix existing indexes on textual columns.

- Set locale environment variables during postmaster startup to ensure that `plperl` won't change the locale later

This fixes a problem that occurred if the postmaster was started with environment variables specifying a different locale than what `initdb` had been told. Under these conditions, any use of `plperl` was likely to lead to corrupt indexes. You might need `REINDEX` to fix existing indexes on textual columns if this has happened to you.

- Allow more flexible relocation of installation directories (Tom)

Previous releases supported relocation only if all installation directory paths were the same except for the last component.

- Fix longstanding bug in `strpos()` and regular expression handling in certain rarely used Asian multi-byte character sets (Tatsuo)
- Various fixes for functions returning `RECORDS` (Tom)
- Fix bug in `/contrib/pgcrypto` `gen_salt`, which caused it not to use all available salt space for MD5 and XDES algorithms (Marko Kreen, Solar Designer)

Salts for Blowfish and standard DES are unaffected.

- Fix `/contrib/dblink` to throw an error, rather than crashing, when the number of columns specified is different from what's actually returned by the query (Joe)

## E.33. Release 8.0.5

**Release date:** 2005-12-12

This release contains a variety of fixes from 8.0.4.

### E.33.1. Migration to Version 8.0.5

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.3, see the release notes for 8.0.3.

### E.33.2. Changes

- Fix race condition in transaction log management

There was a narrow window in which an I/O operation could be initiated for the wrong page, leading to an Assert failure or data corruption.

- Fix `bgwriter` problems after recovering from errors (Tom)

The background writer was found to leak buffer pins after write errors. While not fatal in itself, this might lead to mysterious blockages of later VACUUM commands.

- Prevent failure if client sends Bind protocol message when current transaction is already aborted
- `/contrib/ltree` fixes (Teodor)
- AIX and HPUX compile fixes (Tom)
- Retry file reads and writes after Windows NO\_SYSTEM\_RESOURCES error (Qingqing Zhou)
- Fix intermittent failure when `log_line_prefix` includes `%i`
- Fix `psql` performance issue with long scripts on Windows (Merlin Moncure)
- Fix missing updates of `pg_group` flat file
- Fix longstanding planning error for outer joins

This bug sometimes caused a bogus error “RIGHT JOIN is only supported with merge-joinable join conditions”.

- Postpone timezone initialization until after `postmaster.pid` is created

This avoids confusing startup scripts that expect the pid file to appear quickly.

- Prevent core dump in `pg_autovacuum` when a table has been dropped
- Fix problems with whole-row references (`foo.*`) to subquery results

## E.34. Release 8.0.4

**Release date:** 2005-10-04

This release contains a variety of fixes from 8.0.3.

### E.34.1. Migration to Version 8.0.4

A dump/restore is not required for those running 8.0.X. However, if you are upgrading from a version earlier than 8.0.3, see the release notes for 8.0.3.

### E.34.2. Changes

- Fix error that allowed VACUUM to remove `ctid` chains too soon, and add more checking in code that follows `ctid` links

This fixes a long-standing problem that could cause crashes in very rare circumstances.

- Fix `CHAR()` to properly pad spaces to the specified length when using a multiple-byte character set (Yoshiyuki Asaba)

In prior releases, the padding of `CHAR()` was incorrect because it only padded to the specified number of bytes without considering how many characters were stored.

- Force a checkpoint before committing `CREATE DATABASE`  
This should fix recent reports of “index is not a btree” failures when a crash occurs shortly after `CREATE DATABASE`.
- Fix the sense of the test for read-only transaction in `COPY`  
The code formerly prohibited `COPY TO`, where it should prohibit `COPY FROM`.
- Handle consecutive embedded newlines in `COPY CSV`-mode input
- Fix `date_trunc(week)` for dates near year end
- Fix planning problem with outer-join `ON` clauses that reference only the inner-side relation
- Further fixes for `x FULL JOIN y ON true` corner cases
- Fix overenthusiastic optimization of `x IN (SELECT DISTINCT ...)` and related cases
- Fix mis-planning of queries with small `LIMIT` values due to poorly thought out “fuzzy” cost comparison
- Make `array_in` and `array_recv` more paranoid about validating their `OID` parameter
- Fix missing rows in queries like `UPDATE a=... WHERE a...` with GiST index on column `a`
- Improve robustness of datetime parsing
- Improve checking for partially-written WAL pages
- Improve robustness of signal handling when SSL is enabled
- Improve MIPS and M68K spinlock code
- Don’t try to open more than `max_files_per_process` files during postmaster startup
- Various memory leakage fixes
- Various portability improvements
- Update timezone data files
- Improve handling of DLL load failures on Windows
- Improve random-number generation on Windows
- Make `psql -f filename` return a nonzero exit code when opening the file fails
- Change `pg_dump` to handle inherited check constraints more reliably
- Fix password prompting in `pg_restore` on Windows
- Fix PL/PgSQL to handle `var := var` correctly when the variable is of pass-by-reference type
- Fix PL/Perl `%_SHARED` so it’s actually shared
- Fix `contrib/pg_autovacuum` to allow sleep intervals over 2000 sec
- Update `contrib/tsearch2` to use current Snowball code

## E.35. Release 8.0.3

**Release date:** 2005-05-09

This release contains a variety of fixes from 8.0.2, including several security-related issues.

### E.35.1. Migration to Version 8.0.3

A dump/restore is not required for those running 8.0.X. However, it is one possible way of handling two significant security problems that have been found in the initial contents of 8.0.X system catalogs. A dump/initdb/reload sequence using 8.0.3's initdb will automatically correct these problems.

The larger security problem is that the built-in character set encoding conversion functions can be invoked from SQL commands by unprivileged users, but the functions were not designed for such use and are not secure against malicious choices of arguments. The fix involves changing the declared parameter list of these functions so that they can no longer be invoked from SQL commands. (This does not affect their normal use by the encoding conversion machinery.)

The lesser problem is that the `contrib/tsearch2` module creates several functions that are improperly declared to return `internal` when they do not accept `internal` arguments. This breaks type safety for all functions using `internal` arguments.

It is strongly recommended that all installations repair these errors, either by `initdb` or by following the manual repair procedure given below. The errors at least allow unprivileged database users to crash their server process, and might allow unprivileged users to gain the privileges of a database superuser.

If you wish not to do an `initdb`, perform the same manual repair procedures shown in the 7.4.8 release notes.

### E.35.2. Changes

- Change encoding function signature to prevent misuse
- Change `contrib/tsearch2` to avoid unsafe use of `INTERNAL` function results
- Guard against incorrect second parameter to `record_out`
- Repair ancient race condition that allowed a transaction to be seen as committed for some purposes (eg `SELECT FOR UPDATE`) slightly sooner than for other purposes

This is an extremely serious bug since it could lead to apparent data inconsistencies being briefly visible to applications.

- Repair race condition between relation extension and `VACUUM`

This could theoretically have caused loss of a page's worth of freshly-inserted data, although the scenario seems of very low probability. There are no known cases of it having caused more than an Assert failure.

- Fix comparisons of `TIME WITH TIME ZONE` values

The comparison code was wrong in the case where the `--enable-integer-datetimes` configuration switch had been used. NOTE: if you have an index on a `TIME WITH TIME ZONE` column, it will need to be `REINDEXED` after installing this update, because the fix corrects the sort order of column values.

- Fix `EXTRACT (EPOCH)` for `TIME WITH TIME ZONE` values
- Fix mis-display of negative fractional seconds in `INTERVAL` values

This error only occurred when the `--enable-integer-datetimes` configuration switch had been used.

- Fix `pg_dump` to dump trigger names containing `%` correctly (Neil)
- Still more 64-bit fixes for `contrib/intagg`
- Prevent incorrect optimization of functions returning `RECORD`
- Prevent crash on `COALESCE (NULL, NULL)`
- Fix Borland makefile for `libpq`
- Fix `contrib/btree_gist` for `timetz` type (Teodor)
- Make `pg_ctl` check the PID found in `postmaster.pid` to see if it is still a live process
- Fix `pg_dump/pg_restore` problems caused by addition of dump timestamps
- Fix interaction between materializing holdable cursors and firing deferred triggers during transaction commit
- Fix memory leak in SQL functions returning pass-by-reference data types

## E.36. Release 8.0.2

**Release date:** 2005-04-07

This release contains a variety of fixes from 8.0.1.

### E.36.1. Migration to Version 8.0.2

A dump/restore is not required for those running 8.0.\*. This release updates the major version number of the PostgreSQL libraries, so it might be necessary to re-link some user applications if they cannot find the properly-numbered shared library.

### E.36.2. Changes

- Increment the major version number of all interface libraries (Bruce)

This should have been done in 8.0.0. It is required so 7.4.X versions of PostgreSQL client applications, like `psql`, can be used on the same machine as 8.0.X applications. This might require re-linking user applications that use these libraries.

- Add Windows-only `wal_sync_method` setting of `fsync_writethrough` (Magnus, Bruce)

This setting causes PostgreSQL to write through any disk-drive write cache when writing to WAL. This behavior was formerly called `fsync`, but was renamed because it acts quite differently from `fsync` on other platforms.

- Enable the `wal_sync_method` setting of `open_datasync` on Windows, and make it the default for that platform (Magnus, Bruce)

Because the default is no longer `fsync_writethrough`, data loss is possible during a power failure if the disk drive has write caching enabled. To turn off the write cache on Windows, from the Device Manager, choose the drive properties, then `Policies`.

- New cache management algorithm 2Q replaces ARC (Tom)

This was done to avoid a pending US patent on ARC. The 2Q code might be a few percentage points slower than ARC for some work loads. A better cache management algorithm will appear in 8.1.

- Planner adjustments to improve behavior on freshly-created tables (Tom)
- Allow `plpgsql` to assign to an element of an array that is initially `NULL` (Tom)

Formerly the array would remain `NULL`, but now it becomes a single-element array. The main SQL engine was changed to handle `UPDATE` of a null array value this way in 8.0, but the similar case in `plpgsql` was overlooked.

- Convert `\r\n` and `\r` to `\n` in `plpython` function bodies (Michael Fuhr)

This prevents syntax errors when `plpython` code is written on a Windows or Mac client.

- Allow SPI cursors to handle utility commands that return rows, such as `EXPLAIN` (Tom)
- Fix `CLUSTER` failure after `ALTER TABLE SET WITHOUT OIDS` (Tom)
- Reduce memory usage of `ALTER TABLE ADD COLUMN` (Neil)
- Fix `ALTER LANGUAGE RENAME` (Tom)
- Document the Windows-only `register` and `unregister` options of `pg_ctl` (Magnus)
- Ensure operations done during backend shutdown are counted by statistics collector

This is expected to resolve reports of `pg_autovacuum` not vacuuming the system catalogs often enough — it was not being told about catalog deletions caused by temporary table removal during backend exit.

- Change the Windows default for configuration parameter `log_destination` to `eventlog` (Magnus)
- Make Kerberos authentication work on Windows (Magnus)
- Allow `ALTER DATABASE RENAME` by superusers who aren't flagged as having `CREATEDB` privilege (Tom)

- Modify WAL log entries for `CREATE` and `DROP DATABASE` to not specify absolute paths (Tom)

This allows point-in-time recovery on a different machine with possibly different database location. Note that `CREATE TABLESPACE` still poses a hazard in such situations.

- Fix crash from a backend exiting with an open transaction that created a table and opened a cursor on it (Tom)
- Fix `array_map()` so it can call PL functions (Tom)
- Several `contrib/tsearch2` and `contrib/btree_gist` fixes (Teodor)
- Fix crash of some `contrib/pgcrypto` functions on some platforms (Marko Kreen)
- Fix `contrib/intagg` for 64-bit platforms (Tom)
- Fix ecpg bugs in parsing of `CREATE` statement (Michael)
- Work around gcc bug on powerpc and amd64 causing problems in ecpg (Christof Petig)
- Do not use locale-aware versions of `upper()`, `lower()`, and `initcap()` when the locale is `C` (Bruce)  
This allows these functions to work on platforms that generate errors for non-7-bit data when the locale is `C`.
- Fix `quote_ident()` to quote names that match keywords (Tom)
- Fix `to_date()` to behave reasonably when `CC` and `YY` fields are both used (Karel)
- Prevent `to_char(interval)` from failing when given a zero-month interval (Tom)
- Fix wrong week returned by `date_trunc('week')` (Bruce)  
`date_trunc('week')` returned the wrong year for the first few days of January in some years.
- Use the correct default mask length for class `D` addresses in `INET` data types (Tom)

## E.37. Release 8.0.1

**Release date:** 2005-01-31

This release contains a variety of fixes from 8.0.0, including several security-related issues.

### E.37.1. Migration to Version 8.0.1

A dump/restore is not required for those running 8.0.0.

### E.37.2. Changes

- Disallow `LOAD` to non-superusers

On platforms that will automatically execute initialization functions of a shared library (this includes at least Windows and ELF-based Unixen), `LOAD` can be used to make the server execute arbitrary code. Thanks to NGS Software for reporting this.

- Check that creator of an aggregate function has the right to execute the specified transition functions

This oversight made it possible to bypass denial of EXECUTE permission on a function.

- Fix security and 64-bit issues in contrib/intagg
- Add needed STRICT marking to some contrib functions (Kris Jurka)
- Avoid buffer overrun when plpgsql cursor declaration has too many parameters (Neil)
- Make `ALTER TABLE ADD COLUMN` enforce domain constraints in all cases
- Fix planning error for FULL and RIGHT outer joins

The result of the join was mistakenly supposed to be sorted the same as the left input. This could not only deliver mis-sorted output to the user, but in case of nested merge joins could give outright wrong answers.

- Improve planning of grouped aggregate queries
- `ROLLBACK TO savepoint` closes cursors created since the savepoint
- Fix inadequate backend stack size on Windows
- Avoid SHGetSpecialFolderPath() on Windows (Magnus)
- Fix some problems in running pg\_autovacuum as a Windows service (Dave Page)
- Multiple minor bug fixes in pg\_dump/pg\_restore
- Fix ecpg segfault with named structs used in typedefs (Michael)

## E.38. Release 8.0

**Release date:** 2005-01-19

### E.38.1. Overview

Major changes in this release:

#### Microsoft Windows Native Server

This is the first PostgreSQL release to run natively on Microsoft Windows® as a server. It can run as a Windows service. This release supports NT-based Windows releases like Windows 2000 SP4, Windows XP, and Windows 2003. Older releases like Windows 95, Windows 98, and Windows ME are not supported because these operating systems do not have the infrastructure to support PostgreSQL. A separate installer project has been created to ease installation on Windows — see <http://www.postgresql.org/ftp/win32/>.

Although tested throughout our release cycle, the Windows port does not have the benefit of years of use in production environments that PostgreSQL has on Unix platforms. Therefore it should be treated with the same level of caution as you would a new product.

Previous releases required the Unix emulation toolkit Cygwin in order to run the server on Windows operating systems. PostgreSQL has supported native clients on Windows for many years.

### Savepoints

Savepoints allow specific parts of a transaction to be aborted without affecting the remainder of the transaction. Prior releases had no such capability; there was no way to recover from a statement failure within a transaction except by aborting the whole transaction. This feature is valuable for application writers who require error recovery within a complex transaction.

### Point-In-Time Recovery

In previous releases there was no way to recover from disk drive failure except to restore from a previous backup or use a standby replication server. Point-in-time recovery allows continuous backup of the server. You can recover either to the point of failure or to some transaction in the past.

### Tablespaces

Tablespaces allow administrators to select different file systems for storage of individual tables, indexes, and databases. This improves performance and control over disk space usage. Prior releases used `initlocation` and manual symlink management for such tasks.

### Improved Buffer Management, `CHECKPOINT`, `VACUUM`

This release has a more intelligent buffer replacement strategy, which will make better use of available shared buffers and improve performance. The performance impact of vacuum and checkpoints is also lessened.

### Change Column Types

A column's data type can now be changed with `ALTER TABLE`.

### New Perl Server-Side Language

A new version of the `plperl` server-side language now supports a persistent shared storage area, triggers, returning records and arrays of records, and SPI calls to access the database.

### Comma-separated-value (CSV) support in `COPY`

`COPY` can now read and write comma-separated-value files. It has the flexibility to interpret nonstandard quoting and separation characters too.

## E.38.2. Migration to Version 8.0

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

Observe the following incompatibilities:

- In `READ COMMITTED` serialization mode, volatile functions now see the results of concurrent transactions committed up to the beginning of each statement within the function, rather than up to the beginning of the interactive command that called the function.
- Functions declared `STABLE` or `IMMUTABLE` always use the snapshot of the calling query, and therefore do not see the effects of actions taken after the calling query starts, whether in their own transaction or other transactions. Such a function must be read-only, too, meaning that it cannot use any SQL commands other than `SELECT`.

- Nondeferred `AFTER` triggers are now fired immediately after completion of the triggering query, rather than upon finishing the current interactive command. This makes a difference when the triggering query occurred within a function: the trigger is invoked before the function proceeds to its next operation.
- Server configuration parameters `virtual_host` and `tcpip_socket` have been replaced with a more general parameter `listen_addresses`. Also, the server now listens on `localhost` by default, which eliminates the need for the `-i` `postmaster` switch in many scenarios.
- Server configuration parameters `SortMem` and `VacuumMem` have been renamed to `work_mem` and `maintenance_work_mem` to better reflect their use. The original names are still supported in `SET` and `SHOW`.
- Server configuration parameters `log_pid`, `log_timestamp`, and `log_source_port` have been replaced with a more general parameter `log_line_prefix`.
- Server configuration parameter `syslog` has been replaced with a more logical `log_destination` variable to control the log output destination.
- Server configuration parameter `log_statement` has been changed so it can selectively log just database modification or data definition statements. Server configuration parameter `log_duration` now prints only when `log_statement` prints the query.
- Server configuration parameter `max_expr_depth` parameter has been replaced with `max_stack_depth` which measures the physical stack size rather than the expression nesting depth. This helps prevent session termination due to stack overflow caused by recursive functions.
- The `length()` function no longer counts trailing spaces in `CHAR(n)` values.
- Casting an integer to `BIT(N)` selects the rightmost `N` bits of the integer, not the leftmost `N` bits as before.
- Updating an element or slice of a `NULL` array value now produces a nonnull array result, namely an array containing just the assigned-to positions.
- Syntax checking of array input values has been tightened up considerably. Junk that was previously allowed in odd places with odd results now causes an error. Empty-string element values must now be written as `" "`, rather than writing nothing. Also changed behavior with respect to whitespace surrounding array elements: trailing whitespace is now ignored, for symmetry with leading whitespace (which has always been ignored).
- Overflow in integer arithmetic operations is now detected and reported as an error.
- The arithmetic operators associated with the single-byte `"char"` data type have been removed.
- The `extract()` function (also called `date_part`) now returns the proper year for BC dates. It previously returned one less than the correct year. The function now also returns the proper values for millennium and century.
- CIDR values now must have their nonmasked bits be zero. For example, we no longer allow `204.248.199.1/31` as a CIDR value. Such values should never have been accepted by PostgreSQL and will now be rejected.
- `EXECUTE` now returns a completion tag that matches the executed statement.
- `psql`'s `\copy` command now reads or writes to the query's `stdin/stdout`, rather than `psql`'s `stdin/stdout`. The previous behavior can be accessed via new `pstdin/pstdout` parameters.

- The JDBC client interface has been removed from the core distribution, and is now hosted at <http://jdbc.postgresql.org>.
- The Tcl client interface has also been removed. There are several Tcl interfaces now hosted at <http://gborg.postgresql.org>.
- The server now uses its own time zone database, rather than the one supplied by the operating system. This will provide consistent behavior across all platforms. In most cases, there should be little noticeable difference in time zone behavior, except that the time zone names used by `SET/SHOW TimeZone` might be different from what your platform provides.
- Configure's threading option no longer requires users to run tests or edit configuration files; threading options are now detected automatically.
- Now that tablespaces have been implemented, `initlocation` has been removed.
- The API for user-defined GiST indexes has been changed. The `Union` and `PickSplit` methods are now passed a pointer to a special `GistEntryVector` structure, rather than a `bytea`.

### E.38.3. Deprecated Features

Some aspects of PostgreSQL's behavior have been determined to be suboptimal. For the sake of backward compatibility these have not been removed in 8.0, but they are considered deprecated and will be removed in the next major release.

- The 8.1 release will remove the `to_char()` function for intervals.
- The server now warns of empty strings passed to `oid/float4/float8` data types, but continues to interpret them as zeroes as before. In the next major release, empty strings will be considered invalid input for these data types.
- By default, tables in PostgreSQL 8.0 and earlier are created with `OIDs`. In the next release, this will *not* be the case: to create a table that contains `OIDs`, the `WITH OIDS` clause must be specified or the `default_with_oids` configuration parameter must be set. Users are encouraged to explicitly specify `WITH OIDS` if their tables require `OIDs` for compatibility with future releases of PostgreSQL.

### E.38.4. Changes

Below you will find a detailed account of the changes between release 8.0 and the previous major release.

#### E.38.4.1. Performance Improvements

- Support cross-data-type index usage (Tom)  
Before this change, many queries would not use an index if the data types did not match exactly. This improvement makes index usage more intuitive and consistent.
- New buffer replacement strategy that improves caching (Jan)  
Prior releases used a least-recently-used (LRU) cache to keep recently referenced pages in memory. The LRU algorithm did not consider the number of times a specific cache entry was accessed, so large table

scans could force out useful cache pages. The new cache algorithm uses four separate lists to track most recently used and most frequently used cache pages and dynamically optimize their replacement based on the work load. This should lead to much more efficient use of the shared buffer cache. Administrators who have tested shared buffer sizes in the past should retest with this new cache replacement policy.

- Add subprocess to write dirty buffers periodically to reduce checkpoint writes (Jan)

In previous releases, the checkpoint process, which runs every few minutes, would write all dirty buffers to the operating system's buffer cache then flush all dirty operating system buffers to disk. This resulted in a periodic spike in disk usage that often hurt performance. The new code uses a background writer to trickle disk writes at a steady pace so checkpoints have far fewer dirty pages to write to disk. Also, the new code does not issue a global `sync()` call, but instead `fsync()`s just the files written since the last checkpoint. This should improve performance and minimize degradation during checkpoints.

- Add ability to prolong vacuum to reduce performance impact (Jan)

On busy systems, `VACUUM` performs many I/O requests which can hurt performance for other users. This release allows you to slow down `VACUUM` to reduce its impact on other users, though this increases the total duration of `VACUUM`.

- Improve B-tree index performance for duplicate keys (Dmitry Tkach, Tom)

This improves the way indexes are scanned when many duplicate values exist in the index.

- Use dynamically-generated table size estimates while planning (Tom)

Formerly the planner estimated table sizes using the values seen by the last `VACUUM` or `ANALYZE`, both as to physical table size (number of pages) and number of rows. Now, the current physical table size is obtained from the kernel, and the number of rows is estimated by multiplying the table size by the row density (rows per page) seen by the last `VACUUM` or `ANALYZE`. This should produce more reliable estimates in cases where the table size has changed significantly since the last housekeeping command.

- Improved index usage with `OR` clauses (Tom)

This allows the optimizer to use indexes in statements with many `OR` clauses that would not have been indexed in the past. It can also use multi-column indexes where the first column is specified and the second column is part of an `OR` clause.

- Improve matching of partial index clauses (Tom)

The server is now smarter about using partial indexes in queries involving complex `WHERE` clauses.

- Improve performance of the GEQO optimizer (Tom)

The GEQO optimizer is used to plan queries involving many tables (by default, twelve or more). This release speeds up the way queries are analyzed to decrease time spent in optimization.

- Miscellaneous optimizer improvements

There is not room here to list all the minor improvements made, but numerous special cases work better than in prior releases.

- Improve lookup speed for C functions (Tom)

This release uses a hash table to lookup information for dynamically loaded C functions. This improves their speed so they perform nearly as quickly as functions that are built into the server executable.

- Add type-specific `ANALYZE` statistics capability (Mark Cave-Ayland)

This feature allows more flexibility in generating statistics for nonstandard data types.

- `ANALYZE` now collects statistics for expression indexes (Tom)

Expression indexes (also called functional indexes) allow users to index not just columns but the results of expressions and function calls. With this release, the optimizer can gather and use statistics about the contents of expression indexes. This will greatly improve the quality of planning for queries in which an expression index is relevant.

- New two-stage sampling method for `ANALYZE` (Manfred Koizar)

This gives better statistics when the density of valid rows is very different in different regions of a table.

- Speed up `TRUNCATE` (Tom)

This buys back some of the performance loss observed in 7.4, while still keeping `TRUNCATE` transaction-safe.

### E.38.4.2. Server Changes

- Add WAL file archiving and point-in-time recovery (Simon Riggs)
- Add tablespaces so admins can control disk layout (Gavin)
- Add a built-in log rotation program (Andreas Pflug)

It is now possible to log server messages conveniently without relying on either syslog or an external log rotation program.

- Add new read-only server configuration parameters to show server compile-time settings: `block_size`, `integer_datetimes`, `max_function_args`, `max_identifier_length`, `max_index_keys` (Joe)
- Make quoting of `sameuser`, `samegroup`, and `all` remove special meaning of these terms in `pg_hba.conf` (Andrew)
- Use clearer IPv6 name `::1/128` for `localhost` in default `pg_hba.conf` (Andrew)
- Use CIDR format in `pg_hba.conf` examples (Andrew)

- Rename server configuration parameters `SortMem` and `VacuumMem` to `work_mem` and `maintenance_work_mem` (Old names still supported) (Tom)

This change was made to clarify that bulk operations such as index and foreign key creation use `maintenance_work_mem`, while `work_mem` is for workspaces used during query execution.

- Allow logging of session disconnections using server configuration `log_disconnections` (Andrew)
- Add new server configuration parameter `log_line_prefix` to allow control of information emitted in each log line (Andrew)

Available information includes user name, database name, remote IP address, and session start time.

- Remove server configuration parameters `log_pid`, `log_timestamp`, `log_source_port`; functionality superseded by `log_line_prefix` (Andrew)
- Replace the `virtual_host` and `tcpip_socket` parameters with a unified `listen_addresses` parameter (Andrew, Tom)

`virtual_host` could only specify a single IP address to listen on. `listen_addresses` allows multiple addresses to be specified.

- Listen on localhost by default, which eliminates the need for the `-i` postmaster switch in many scenarios (Andrew)

Listening on localhost (127.0.0.1) opens no new security holes but allows configurations like Windows and JDBC, which do not support local sockets, to work without special adjustments.

- Remove `syslog` server configuration parameter, and add more logical `log_destination` variable to control log output location (Magnus)
- Change server configuration parameter `log_statement` to take values `all`, `mod`, `ddl`, or `none` to select which queries are logged (Bruce)

This allows administrators to log only data definition changes or only data modification statements.

- Some logging-related configuration parameters could formerly be adjusted by ordinary users, but only in the “more verbose” direction. They are now treated more strictly: only superusers can set them. However, a superuser can use `ALTER USER` to provide per-user settings of these values for non-superusers. Also, it is now possible for superusers to set values of superuser-only configuration parameters via `PGOPTIONS`.

- Allow configuration files to be placed outside the data directory (mlw)

By default, configuration files are kept in the cluster’s top directory. With this addition, configuration files can be placed outside the data directory, easing administration.

- Plan prepared queries only when first executed so constants can be used for statistics (Oliver Jowett)

Prepared statements plan queries once and execute them many times. While prepared queries avoid the overhead of re-planning on each use, the quality of the plan suffers from not knowing the exact parameters to be used in the query. In this release, planning of unnamed prepared statements is delayed until the first execution, and the actual parameter values of that execution are used as optimization hints. This allows use of out-of-line parameter passing without incurring a performance penalty.

- Allow `DECLARE CURSOR` to take parameters (Oliver Jowett)

It is now useful to issue `DECLARE CURSOR` in a `Parse` message with parameters. The parameter values sent at `Bind` time will be substituted into the execution of the cursor’s query.

- Fix hash joins and aggregates of `inet` and `cidr` data types (Tom)

Release 7.4 handled hashing of mixed `inet` and `cidr` values incorrectly. (This bug did not exist in prior releases because they wouldn’t try to hash either data type.)

- Make `log_duration` print only when `log_statement` prints the query (Ed L.)

### E.38.4.3. Query Changes

- Add savepoints (nested transactions) (Alvaro)
- Unsupported isolation levels are now accepted and promoted to the nearest supported level (Peter)

The SQL specification states that if a database doesn’t support a specific isolation level, it should use the next more restrictive level. This change complies with that recommendation.

- Allow `BEGIN WORK` to specify transaction isolation levels like `START TRANSACTION` does (Bruce)

- Fix table permission checking for cases in which rules generate a query type different from the originally submitted query (Tom)
- Implement dollar quoting to simplify single-quote usage (Andrew, Tom, David Fetter)
 

In previous releases, because single quotes had to be used to quote a function's body, the use of single quotes inside the function text required use of two single quotes or other error-prone notations. With this release we add the ability to use "dollar quoting" to quote a block of text. The ability to use different quoting delimiters at different nesting levels greatly simplifies the task of quoting correctly, especially in complex functions. Dollar quoting can be used anywhere quoted text is needed.
- Make `CASE val WHEN compval1 THEN ... evaluate val` only once (Tom)
 

`CASE` no longer evaluates the tested expression multiple times. This has benefits when the expression is complex or is volatile.
- Test `HAVING` before computing target list of an aggregate query (Tom)
 

Fixes improper failure of cases such as `SELECT SUM(win)/SUM(lose) ... GROUP BY ... HAVING SUM(lose) > 0`. This should work but formerly could fail with divide-by-zero.
- Replace `max_expr_depth` parameter with `max_stack_depth` parameter, measured in kilobytes of stack size (Tom)
 

This gives us a fairly bulletproof defense against crashing due to runaway recursive functions. Instead of measuring the depth of expression nesting, we now directly measure the size of the execution stack.
- Allow arbitrary row expressions (Tom)
 

This release allows SQL expressions to contain arbitrary composite types, that is, row values. It also allows functions to more easily take rows as arguments and return row values.
- Allow `LIKE/ILIKE` to be used as the operator in row and subselect comparisons (Fabien Coelho)
- Avoid locale-specific case conversion of basic ASCII letters in identifiers and keywords (Tom)
 

This solves the "Turkish problem" with mangling of words containing `İ` and `ı`. Folding of characters outside the 7-bit-ASCII set is still locale-aware.
- Improve syntax error reporting (Fabien, Tom)
 

Syntax error reports are more useful than before.
- Change `EXECUTE` to return a completion tag matching the executed statement (Kris Jurka)
 

Previous releases return an `EXECUTE` tag for any `EXECUTE` call. In this release, the tag returned will reflect the command executed.
- Avoid emitting `NATURAL CROSS JOIN` in rule listings (Tom)
 

Such a clause makes no logical sense, but in some cases the rule decompiler formerly produced this syntax.

#### E.38.4.4. Object Manipulation Changes

- Add `COMMENT ON` for casts, conversions, languages, operator classes, and large objects (Christopher)
- Add new server configuration parameter `default_with_oids` to control whether tables are created with `OIDs` by default (Neil)

This allows administrators to control whether `CREATE TABLE` commands create tables with or without `OID` columns by default. (Note: the current factory default setting for `default_with_oids` is `TRUE`, but the default will become `FALSE` in future releases.)

- Add `WITH / WITHOUT OIDS` clause to `CREATE TABLE AS` (Neil)
- Allow `ALTER TABLE DROP COLUMN` to drop an `OID` column (`ALTER TABLE SET WITHOUT OIDS` still works) (Tom)
- Allow composite types as table columns (Tom)
- Allow `ALTER ... ADD COLUMN` with defaults and `NOT NULL` constraints; works per SQL spec (Rod)

It is now possible for `ADD COLUMN` to create a column that is not initially filled with `NULL`s, but with a specified default value.

- Add `ALTER COLUMN TYPE` to change column's type (Rod)

It is now possible to alter a column's data type without dropping and re-adding the column.

- Allow multiple `ALTER` actions in a single `ALTER TABLE` command (Rod)

This is particularly useful for `ALTER` commands that rewrite the table (which include `ALTER COLUMN TYPE` and `ADD COLUMN` with a default). By grouping `ALTER` commands together, the table need be rewritten only once.

- Allow `ALTER TABLE` to add `SERIAL` columns (Tom)

This falls out from the new capability of specifying defaults for new columns.

- Allow changing the owners of aggregates, conversions, databases, functions, operators, operator classes, schemas, types, and tablespaces (Christopher, Euler Taveira de Oliveira)

Previously this required modifying the system tables directly.

- Allow temporary object creation to be limited to `SECURITY DEFINER` functions (Sean Chittenden)
- Add `ALTER TABLE ... SET WITHOUT CLUSTER` (Christopher)

Prior to this release, there was no way to clear an auto-cluster specification except to modify the system tables.

- Constraint/Index/SERIAL names are now `table_column_type` with numbers appended to guarantee uniqueness within the schema (Tom)

The SQL specification states that such names should be unique within a schema.

- Add `pg_get_serial_sequence()` to return a `SERIAL` column's sequence name (Christopher)

This allows automated scripts to reliably find the `SERIAL` sequence name.

- Warn when primary/foreign key data type mismatch requires costly lookup
- New `ALTER INDEX` command to allow moving of indexes between tablespaces (Gavin)
- Make `ALTER TABLE OWNER` change dependent sequence ownership too (Alvaro)

### E.38.4.5. Utility Command Changes

- Allow `CREATE SCHEMA` to create triggers, indexes, and sequences (Neil)

- Add `ALSO` keyword to `CREATE RULE` (Fabien Coelho)

This allows `ALSO` to be added to rule creation to contrast it with `INSTEAD` rules.

- Add `NOWAIT` option to `LOCK` (Tatsuo)

This allows the `LOCK` command to fail if it would have to wait for the requested lock.

- Allow `COPY` to read and write comma-separated-value (CSV) files (Andrew, Bruce)
- Generate error if the `COPY` delimiter and `NULL` string conflict (Bruce)
- `GRANT/REVOKE` behavior follows the SQL spec more closely
- Avoid locking conflict between `CREATE INDEX` and `CHECKPOINT` (Tom)

In 7.3 and 7.4, a long-running B-tree index build could block concurrent `CHECKPOINTS` from completing, thereby causing WAL bloat because the WAL log could not be recycled.

- Database-wide `ANALYZE` does not hold locks across tables (Tom)

This reduces the potential for deadlocks against other backends that want exclusive locks on tables. To get the benefit of this change, do not execute database-wide `ANALYZE` inside a transaction block (`BEGIN` block); it must be able to commit and start a new transaction for each table.

- `REINDEX` does not exclusively lock the index's parent table anymore

The index itself is still exclusively locked, but readers of the table can continue if they are not using the particular index being rebuilt.

- Erase MD5 user passwords when a user is renamed (Bruce)

PostgreSQL uses the user name as salt when encrypting passwords via MD5. When a user's name is changed, the salt will no longer match the stored MD5 password, so the stored password becomes useless. In this release a notice is generated and the password is cleared. A new password must then be assigned if the user is to be able to log in with a password.

- New `pg_ctl kill` option for Windows (Andrew)

Windows does not have a `kill` command to send signals to backends so this capability was added to `pg_ctl`.

- Information schema improvements
- Add `--pwfile` option to `initdb` so the initial password can be set by GUI tools (Magnus)
- Detect locale/encoding mismatch in `initdb` (Peter)
- Add `register` command to `pg_ctl` to register Windows operating system service (Dave Page)

### E.38.4.6. Data Type and Function Changes

- More complete support for composite types (row types) (Tom)

Composite values can be used in many places where only scalar values worked before.

- Reject nonrectangular array values as erroneous (Joe)

Formerly, `array_in` would silently build a surprising result.

- Overflow in integer arithmetic operations is now detected (Tom)

- The arithmetic operators associated with the single-byte `"char"` data type have been removed.

Formerly, the parser would select these operators in many situations where an “unable to select an operator” error would be more appropriate, such as `null * null`. If you actually want to do arithmetic on a `"char"` column, you can cast it to integer explicitly.

- Syntax checking of array input values considerably tightened up (Joe)

Junk that was previously allowed in odd places with odd results now causes an `ERROR`, for example, non-whitespace after the closing right brace.

- Empty-string array element values must now be written as `" "`, rather than writing nothing (Joe)

Formerly, both ways of writing an empty-string element value were allowed, but now a quoted empty string is required. The case where nothing at all appears will probably be considered to be a `NULL` element value in some future release.

- Array element trailing whitespace is now ignored (Joe)

Formerly leading whitespace was ignored, but trailing whitespace between an element value and the delimiter or right brace was significant. Now trailing whitespace is also ignored.

- Emit array values with explicit array bounds when lower bound is not one (Joe)
- Accept `YYYY-monthname-DD` as a date string (Tom)
- Make `netmask` and `hostmask` functions return maximum-length mask length (Tom)
- Change factorial function to return `numeric` (Gavin)

Returning `numeric` allows the factorial function to work for a wider range of input values.

- `to_char/to_date()` date conversion improvements (Kurt Roeckx, Fabien Coelho)
- Make `length()` disregard trailing spaces in `CHAR(n)` (Gavin)

This change was made to improve consistency: trailing spaces are semantically insignificant in `CHAR(n)` data, so they should not be counted by `length()`.

- Warn about empty string being passed to `OID/float4/float8` data types (Neil)

`8.1` will throw an error instead.

- Allow leading or trailing whitespace in `int2/int4/int8/float4/float8` input routines (Neil)
- Better support for IEEE Infinity and NaN values in `float4/float8` (Neil)

These should now work on all platforms that support IEEE-compliant floating point arithmetic.

- Add week option to `date_trunc()` (Robert Creager)
- Fix `to_char` for 1 BC (previously it returned 1 AD) (Bruce)
- Fix `date_part(year)` for BC dates (previously it returned one less than the correct year) (Bruce)
- Fix `date_part()` to return the proper millennium and century (Fabien Coelho)

In previous versions, the century and millennium results had a wrong number and started in the wrong year, as compared to standard reckoning of such things.

- Add `ceiling()` as an alias for `ceil()`, and `power()` as an alias for `pow()` for standards compliance (Neil)

- Change `ln()`, `log()`, `power()`, and `sqrt()` to emit the correct `SQLSTATE` error codes for certain error conditions, as specified by SQL:2003 (Neil)
- Add `width_bucket()` function as defined by SQL:2003 (Neil)
- Add `generate_series()` functions to simplify working with numeric sets (Joe)
- Fix `upper/lower/initcap()` functions to work with multibyte encodings (Tom)
- Add boolean and bitwise integer `AND/OR` aggregates (Fabien Coelho)
- New session information functions to return network addresses for client and server (Sean Chittenden)
- Add function to determine the area of a closed path (Sean Chittenden)
- Add function to send cancel request to other backends (Magnus)
- Add `interval plus datetime` operators (Tom)

The reverse ordering, `datetime plus interval`, was already supported, but both are required by the SQL standard.

- Casting an integer to `BIT(N)` selects the rightmost N bits of the integer (Tom)

In prior releases, the leftmost N bits were selected, but this was deemed unhelpful, not to mention inconsistent with casting from bit to int.

- Require `CIDR` values to have all nonmasked bits be zero (Kevin Brintnall)

### E.38.4.7. Server-Side Language Changes

- In `READ COMMITTED` serialization mode, volatile functions now see the results of concurrent transactions committed up to the beginning of each statement within the function, rather than up to the beginning of the interactive command that called the function.
- Functions declared `STABLE` or `IMMUTABLE` always use the snapshot of the calling query, and therefore do not see the effects of actions taken after the calling query starts, whether in their own transaction or other transactions. Such a function must be read-only, too, meaning that it cannot use any SQL commands other than `SELECT`. There is a considerable performance gain from declaring a function `STABLE` or `IMMUTABLE` rather than `VOLATILE`.
- Nondeferred `AFTER` triggers are now fired immediately after completion of the triggering query, rather than upon finishing the current interactive command. This makes a difference when the triggering query occurred within a function: the trigger is invoked before the function proceeds to its next operation. For example, if a function inserts a new row into a table, any nondeferred foreign key checks occur before proceeding with the function.
- Allow function parameters to be declared with names (Dennis Björklund)

This allows better documentation of functions. Whether the names actually do anything depends on the specific function language being used.

- Allow PL/pgSQL parameter names to be referenced in the function (Dennis Björklund)

This basically creates an automatic alias for each named parameter.

- Do minimal syntax checking of PL/pgSQL functions at creation time (Tom)

This allows us to catch simple syntax errors sooner.

- More support for composite types (row and record variables) in PL/pgSQL

For example, it now works to pass a rowtype variable to another function as a single variable.

- Default values for PL/pgSQL variables can now reference previously declared variables
- Improve parsing of PL/pgSQL FOR loops (Tom)

Parsing is now driven by presence of " . . " rather than data type of FOR variable. This makes no difference for correct functions, but should result in more understandable error messages when a mistake is made.

- Major overhaul of PL/Perl server-side language (Command Prompt, Andrew Dunstan)
- In PL/Tcl, SPI commands are now run in subtransactions. If an error occurs, the subtransaction is cleaned up and the error is reported as an ordinary Tcl error, which can be trapped with `catch`. Formerly, it was not possible to catch such errors.
- Accept `ELSEIF` in PL/pgSQL (Neil)

Previously PL/pgSQL only allowed `ELSIF`, but many people are accustomed to spelling this keyword `ELSEIF`.

### E.38.4.8. psql Changes

- Improve psql information display about database objects (Christopher)
- Allow psql to display group membership in `\du` and `\dg` (Markus Bertheau)
- Prevent psql `\dn` from showing temporary schemas (Bruce)
- Allow psql to handle tilde user expansion for file names (Zach Irmen)
- Allow psql to display fancy prompts, including color, via readline (Reece Hart, Chet Ramey)
- Make psql `\copy` match `COPY` command syntax fully (Tom)
- Show the location of syntax errors (Fabien Coelho, Tom)
- Add `CLUSTER` information to psql `\d` display (Bruce)
- Change psql `\copy stdin/stdout` to read from command input/output (Bruce)
- Add `pstdin/pstdout` to read from psql's `stdin/stdout` (Mark Feit)
- Add global psql configuration file, `psqlrc.sample` (Bruce)

This allows a central file where global psql startup commands can be stored.

- Have psql `\d+` indicate if the table has an `OID` column (Neil)
- On Windows, use binary mode in psql when reading files so control-Z is not seen as end-of-file
- Have `\dn+` show permissions and description for schemas (Dennis Björklund)
- Improve tab completion support (Stefan Kaltenbrunn, Greg Sabino Mullane)
- Allow boolean settings to be set using upper or lower case (Michael Paesold)

### E.38.4.9. `pg_dump` Changes

- Use dependency information to improve the reliability of `pg_dump` (Tom)  
This should solve the longstanding problems with related objects sometimes being dumped in the wrong order.
- Have `pg_dump` output objects in alphabetical order if possible (Tom)  
This should make it easier to identify changes between dump files.
- Allow `pg_restore` to ignore some SQL errors (Fabien Coelho)  
This makes `pg_restore`'s behavior similar to the results of feeding a `pg_dump` output script to `psql`. In most cases, ignoring errors and plowing ahead is the most useful thing to do. Also added was a `pg_restore` option to give the old behavior of exiting on an error.
- `pg_restore -l` display now includes objects' schema names
- New begin/end markers in `pg_dump` text output (Bruce)
- Add start/stop times for `pg_dump/pg_dumpall` in verbose mode (Bruce)
- Allow most `pg_dump` options in `pg_dumpall` (Christopher)
- Have `pg_dump` use `ALTER OWNER` rather than `SET SESSION AUTHORIZATION` by default (Christopher)

### E.38.4.10. `libpq` Changes

- Make `libpq`'s `SIGPIPE` handling thread-safe (Bruce)
- Add `PQmbdsplen()` which returns the display length of a character (Tatsuo)
- Add thread locking to SSL and Kerberos connections (Manfred Spraul)
- Allow `PQoidValue()`, `PQcmdTuples()`, and `PQoidStatus()` to work on `EXECUTE` commands (Neil)
- Add `PQserverVersion()` to provide more convenient access to the server version number (Greg Sabino Mullane)
- Add `PQprepare/PQsendPrepared()` functions to support preparing statements without necessarily specifying the data types of their parameters (Abhijit Menon-Sen)
- Many ECPG improvements, including `SET DESCRIPTOR` (Michael)

### E.38.4.11. Source Code Changes

- Allow the database server to run natively on Windows (Claudio, Magnus, Andrew)
- Shell script commands converted to C versions for Windows support (Andrew)
- Create an extension makefile framework (Fabien Coelho, Peter)

This simplifies the task of building extensions outside the original source tree.

- Support relocatable installations (Bruce)

Directory paths for installed files (such as the `/share` directory) are now computed relative to the actual location of the executables, so that an installation tree can be moved to another place without reconfiguring and rebuilding.

- Use `--with-docdir` to choose installation location of documentation; also allow `--infodir` (Peter)
- Add `--without-docdir` to prevent installation of documentation (Peter)
- Upgrade to DocBook V4.2 SGML (Peter)
- New PostgreSQL CVS tag (Marc)

This was done to make it easier for organizations to manage their own copies of the PostgreSQL CVS repository. File version stamps from the master repository will not get munged by checking into or out of a copied repository.

- Clarify locking code (Manfred Koizar)
- Buffer manager cleanup (Neil)
- Decouple platform tests from CPU spinlock code (Bruce, Tom)
- Add inlined test-and-set code on PA-RISC for gcc (ViSolve, Tom)
- Improve i386 spinlock code (Manfred Spraul)
- Clean up spinlock assembly code to avoid warnings from newer gcc releases (Tom)
- Remove JDBC from source tree; now a separate project
- Remove the libpgtcl client interface; now a separate project
- More accurately estimate memory and file descriptor usage (Tom)
- Improvements to the Mac OS X startup scripts (Ray A.)
- New `fsync()` test program (Bruce)
- Major documentation improvements (Neil, Peter)
- Remove `pg_encoding`; not needed anymore
- Remove `pg_id`; not needed anymore
- Remove `initlocation`; not needed anymore
- Auto-detect thread flags (no more manual testing) (Bruce)
- Use Olson's public domain timezone library (Magnus)
- With threading enabled, use thread flags on Unixware for backend executables too (Bruce)

Unixware cannot mix threaded and nonthreaded object files in the same executable, so everything must be compiled as threaded.

- `psql` now uses a flex-generated lexical analyzer to process command strings
- Reimplement the linked list data structure used throughout the backend (Neil)

This improves performance by allowing list append and length operations to be more efficient.

- Allow dynamically loaded modules to create their own server configuration parameters (Thomas Hallgren)

- New Brazilian version of FAQ (Euler Taveira de Oliveira)
- Add French FAQ (Guillaume Lelarge)
- New pgevent for Windows logging
- Make libpq and ECPG build as proper shared libraries on OS X (Tom)

### **E.38.4.12. Contrib Changes**

- Overhaul of contrib/dblink (Joe)
- contrib/dbmirror improvements (Steven Singer)
- New contrib/xml2 (John Gray, Torchbox)
- Updated contrib/mysql
- New version of contrib/btree\_gist (Teodor)
- New contrib/trgm, trigram matching for PostgreSQL (Teodor)
- Many contrib/tsearch2 improvements (Teodor)
- Add double metaphone to contrib/fuzzystrmatch (Andrew)
- Allow contrib/pg\_autovacuum to run as a Windows service (Dave Page)
- Add functions to contrib/dbsize (Andreas Pflug)
- Removed contrib/pg\_logger: obsoleted by integrated logging subprocess
- Removed contrib/rserv: obsoleted by various separate projects

## **E.39. Release 7.4.19**

**Release date:** 2008-01-07

This release contains a variety of fixes from 7.4.18, including fixes for significant security issues.

### **E.39.1. Migration to Version 7.4.19**

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

## E.39.2. Changes

- Prevent functions in indexes from executing with the privileges of the user running `VACUUM`, `ANALYZE`, etc (Tom)

Functions used in index expressions and partial-index predicates are evaluated whenever a new table entry is made. It has long been understood that this poses a risk of trojan-horse code execution if one modifies a table owned by an untrustworthy user. (Note that triggers, defaults, check constraints, etc. pose the same type of risk.) But functions in indexes pose extra danger because they will be executed by routine maintenance operations such as `VACUUM FULL`, which are commonly performed automatically under a superuser account. For example, a nefarious user can execute code with superuser privileges by setting up a trojan-horse index definition and waiting for the next routine vacuum. The fix arranges for standard maintenance operations (including `VACUUM`, `ANALYZE`, `REINDEX`, and `CLUSTER`) to execute as the table owner rather than the calling user, using the same privilege-switching mechanism already used for `SECURITY DEFINER` functions. To prevent bypassing this security measure, execution of `SET SESSION AUTHORIZATION` and `SET ROLE` is now forbidden within a `SECURITY DEFINER` context. (CVE-2007-6600)

- Repair assorted bugs in the regular-expression package (Tom, Will Drewry)

Suitably crafted regular-expression patterns could cause crashes, infinite or near-infinite looping, and/or massive memory consumption, all of which pose denial-of-service hazards for applications that accept regex search patterns from untrustworthy sources. (CVE-2007-4769, CVE-2007-4772, CVE-2007-6067)

- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

The fix that appeared for this in 7.4.18 was incomplete, as it plugged the hole for only some `dblink` functions. (CVE-2007-6601, CVE-2007-3278)

- Fix planner failure in some cases of `WHERE false AND var IN (SELECT ...)` (Tom)
- Fix potential crash in `translate()` when using a multibyte database encoding (Tom)
- Fix PL/Python to not crash on long exception messages (Alvaro)
- `ecpg` parser fixes (Michael)
- Make `contrib/tablefunc`'s `crosstab()` handle `NULL` rowid as a category in its own right, rather than crashing (Joe)
- Fix `tsvector` and `tsquery` output routines to escape backslashes correctly (Teodor, Bruce)
- Fix crash of `to_tsvector()` on huge input strings (Teodor)
- Require a specific version of Autoconf to be used when re-generating the `configure` script (Peter)

This affects developers and packagers only. The change was made to prevent accidental use of untested combinations of Autoconf and PostgreSQL versions. You can remove the version check if you really want to use a different Autoconf version, but it's your responsibility whether the result works or not.

## E.40. Release 7.4.18

**Release date:** 2007-09-17

This release contains fixes from 7.4.17.

### E.40.1. Migration to Version 7.4.18

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

### E.40.2. Changes

- Prevent index corruption when a transaction inserts rows and then aborts close to the end of a concurrent `VACUUM` on the same table (Tom)
- Make `CREATE DOMAIN ... DEFAULT NULL` work properly (Tom)
- Fix excessive logging of SSL error messages (Tom)
- Fix crash when `log_min_error_statement` logging runs out of memory (Tom)
- Prevent `CLUSTER` from failing due to attempting to process temporary tables of other sessions (Alvaro)
- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

## E.41. Release 7.4.17

**Release date:** 2007-04-23

This release contains fixes from 7.4.16, including a security fix.

### E.41.1. Migration to Version 7.4.17

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

## E.41.2. Changes

- Support explicit placement of the temporary-table schema within `search_path`, and disable searching it for functions and operators (Tom)

This is needed to allow a security-definer function to set a truly secure value of `search_path`. Without it, an unprivileged SQL user can use temporary objects to execute code with the privileges of the security-definer function (CVE-2007-2138). See `CREATE FUNCTION` for more information.

- `/contrib/tsearch2` crash fixes (Teodor)
- Fix potential-data-corruption bug in how `VACUUM FULL` handles `UPDATE` chains (Tom, Pavan Deolasee)
- Fix PANIC during enlargement of a hash index (bug introduced in 7.4.15) (Tom)

## E.42. Release 7.4.16

**Release date:** 2007-02-05

This release contains a variety of fixes from 7.4.15, including a security fix.

### E.42.1. Migration to Version 7.4.16

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

## E.42.2. Changes

- Remove security vulnerability that allowed connected users to read backend memory (Tom)

The vulnerability involves suppressing the normal check that a SQL function returns the data type it's declared to, or changing the data type of a table column used in a SQL function (CVE-2007-0555). This error can easily be exploited to cause a backend crash, and in principle might be used to read database content that the user should not be able to access.

- Fix rare bug wherein btree index page splits could fail due to choosing an infeasible split point (Heikki Linnakangas)
- Fix for rare `Assert()` crash triggered by `UNION` (Tom)
- Tighten security of multi-byte character processing for UTF8 sequences over three bytes long (Tom)

## E.43. Release 7.4.15

**Release date:** 2007-01-08

This release contains a variety of fixes from 7.4.14.

### E.43.1. Migration to Version 7.4.15

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

### E.43.2. Changes

- Improve handling of `getaddrinfo()` on AIX (Tom)  
This fixes a problem with starting the statistics collector, among other things.
- Fix “failed to re-find parent key” errors in `VACUUM` (Tom)
- Fix bugs affecting multi-gigabyte hash indexes (Tom)
- Fix error when constructing an `ARRAY[]` made up of multiple empty elements (Tom)
- `to_number()` and `to_char(numeric)` are now `STABLE`, not `IMMUTABLE`, for new `initdb` installs (Tom)  
This is because `lc_numeric` can potentially change the output of these functions.
- Improve index usage of regular expressions that use parentheses (Tom)  
This improves `psql \d` performance also.

## E.44. Release 7.4.14

**Release date:** 2006-10-16

This release contains a variety of fixes from 7.4.13.

### E.44.1. Migration to Version 7.4.14

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

## E.44.2. Changes

- Fix core dump when an untyped literal is taken as ANYARRAY
- Fix `string_to_array()` to handle overlapping matches for the separator string  
For example, `string_to_array('123xx456xxx789', 'xx')`.
- Fix corner cases in pattern matching for `psql`'s `\d` commands
- Fix index-corrupting bugs in `/contrib/ltree` (Teodor)
- Fix backslash escaping in `/contrib/dbmirror`
- Adjust regression tests for recent changes in US DST laws

## E.45. Release 7.4.13

**Release date:** 2006-05-23

This release contains a variety of fixes from 7.4.12, including patches for extremely serious security issues.

### E.45.1. Migration to Version 7.4.13

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

Full security against the SQL-injection attacks described in CVE-2006-2313 and CVE-2006-2314 might require changes in application code. If you have applications that embed untrustworthy strings into SQL commands, you should examine them as soon as possible to ensure that they are using recommended escaping techniques. In most cases, applications should be using subroutines provided by libraries or drivers (such as `libpq`'s `PQescapeStringConn()`) to perform string escaping, rather than relying on *ad hoc* code to do it.

### E.45.2. Changes

- Change the server to reject invalidly-encoded multibyte characters in all cases (Tatsuo, Tom)

While PostgreSQL has been moving in this direction for some time, the checks are now applied uniformly to all encodings and all textual input, and are now always errors not merely warnings. This change defends against SQL-injection attacks of the type described in CVE-2006-2313.

- Reject unsafe uses of `\'` in string literals

As a server-side defense against SQL-injection attacks of the type described in CVE-2006-2314, the server now only accepts `"` and not `\'` as a representation of ASCII single quote in SQL string literals.

By default, `\'` is rejected only when `client_encoding` is set to a client-only encoding (SJIS, BIG5, GBK, GB18030, or UHC), which is the scenario in which SQL injection is possible. A new configuration parameter `backslash_quote` is available to adjust this behavior when needed. Note that full security against CVE-2006-2314 might require client-side changes; the purpose of `backslash_quote` is in part to make it obvious that insecure clients are insecure.

- Modify `libpq`'s string-escaping routines to be aware of encoding considerations and `standard_conforming_strings`

This fixes `libpq`-using applications for the security issues described in CVE-2006-2313 and CVE-2006-2314, and also future-proofs them against the planned changeover to SQL-standard string literal syntax. Applications that use multiple PostgreSQL connections concurrently should migrate to `PQescapeStringConn()` and `PQescapeByteaConn()` to ensure that escaping is done correctly for the settings in use in each database connection. Applications that do string escaping “by hand” should be modified to rely on library routines instead.

- Fix some incorrect encoding conversion functions

`win1251_to_iso`, `alt_to_iso`, `euc_tw_to_big5`, `euc_tw_to_mic`, `mic_to_euc_tw` were all broken to varying extents.

- Clean up stray remaining uses of `\'` in strings (Bruce, Jan)
- Fix bug that sometimes caused OR'd index scans to miss rows they should have returned
- Fix WAL replay for case where a btree index has been truncated
- Fix `SIMILAR TO` for patterns involving `|` (Tom)
- Fix server to use custom DH SSL parameters correctly (Michael Fuhr)
- Fix for Bonjour on Intel Macs (Ashley Clark)
- Fix various minor memory leaks

## E.46. Release 7.4.12

**Release date:** 2006-02-14

This release contains a variety of fixes from 7.4.11.

### E.46.1. Migration to Version 7.4.12

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.11, see the release notes for 7.4.11.

## E.46.2. Changes

- Fix potential crash in `SET SESSION AUTHORIZATION` (CVE-2006-0553)

An unprivileged user could crash the server process, resulting in momentary denial of service to other users, if the server has been compiled with Asserts enabled (which is not the default). Thanks to Akio Ishida for reporting this problem.

- Fix bug with row visibility logic in self-inserted rows (Tom)

Under rare circumstances a row inserted by the current command could be seen as already valid, when it should not be. Repairs bug created in 7.4.9 and 7.3.11 releases.

- Fix race condition that could lead to “file already exists” errors during `pg_clog` file creation (Tom)
- Properly check `DOMAIN` constraints for `UNKNOWN` parameters in prepared statements (Neil)
- Fix to allow restoring dumps that have cross-schema references to custom operators (Tom)
- Portability fix for testing presence of `finite` and `isinf` during configure (Tom)

## E.47. Release 7.4.11

**Release date:** 2006-01-09

This release contains a variety of fixes from 7.4.10.

### E.47.1. Migration to Version 7.4.11

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.8, see the release notes for 7.4.8. Also, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the locale or `plperl` issues described below.

### E.47.2. Changes

- Fix for protocol-level Describe messages issued outside a transaction or in a failed transaction (Tom)
- Fix character string comparison for locales that consider different character combinations as equal, such as Hungarian (Tom)

This might require `REINDEX` to fix existing indexes on textual columns.

- Set locale environment variables during postmaster startup to ensure that `plperl` won't change the locale later

This fixes a problem that occurred if the postmaster was started with environment variables specifying a different locale than what `initdb` had been told. Under these conditions, any use of `plperl` was likely

to lead to corrupt indexes. You might need `REINDEX` to fix existing indexes on textual columns if this has happened to you.

- Fix longstanding bug in `strpos()` and regular expression handling in certain rarely used Asian multi-byte character sets (Tatsuo)
- Fix bug in `/contrib/pgcrypto` `gen_salt`, which caused it not to use all available salt space for MD5 and XDES algorithms (Marko Kreen, Solar Designer)  
Salts for Blowfish and standard DES are unaffected.
- Fix `/contrib/dblink` to throw an error, rather than crashing, when the number of columns specified is different from what's actually returned by the query (Joe)

## E.48. Release 7.4.10

**Release date:** 2005-12-12

This release contains a variety of fixes from 7.4.9.

### E.48.1. Migration to Version 7.4.10

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.8, see the release notes for 7.4.8.

### E.48.2. Changes

- Fix race condition in transaction log management

There was a narrow window in which an I/O operation could be initiated for the wrong page, leading to an Assert failure or data corruption.

- Prevent failure if client sends Bind protocol message when current transaction is already aborted
- `/contrib/ltree` fixes (Teodor)
- AIX and HP/UX compile fixes (Tom)
- Fix longstanding planning error for outer joins

This bug sometimes caused a bogus error “RIGHT JOIN is only supported with merge-joinable join conditions”.

- Prevent core dump in `pg_autovacuum` when a table has been dropped

## E.49. Release 7.4.9

**Release date:** 2005-10-04

This release contains a variety of fixes from 7.4.8.

### E.49.1. Migration to Version 7.4.9

A dump/restore is not required for those running 7.4.X. However, if you are upgrading from a version earlier than 7.4.8, see the release notes for 7.4.8.

### E.49.2. Changes

- Fix error that allowed `VACUUM` to remove `ctid` chains too soon, and add more checking in code that follows `ctid` links

This fixes a long-standing problem that could cause crashes in very rare circumstances.

- Fix `CHAR()` to properly pad spaces to the specified length when using a multiple-byte character set (Yoshiyuki Asaba)

In prior releases, the padding of `CHAR()` was incorrect because it only padded to the specified number of bytes without considering how many characters were stored.

- Fix the sense of the test for read-only transaction in `COPY`

The code formerly prohibited `COPY TO`, where it should prohibit `COPY FROM`.

- Fix planning problem with outer-join `ON` clauses that reference only the inner-side relation
- Further fixes for `x FULL JOIN y ON true` corner cases
- Make `array_in` and `array_recv` more paranoid about validating their `OID` parameter
- Fix missing rows in queries like `UPDATE a=... WHERE a...` with GiST index on column `a`
- Improve robustness of datetime parsing
- Improve checking for partially-written WAL pages
- Improve robustness of signal handling when SSL is enabled
- Don't try to open more than `max_files_per_process` files during postmaster startup
- Various memory leakage fixes
- Various portability improvements
- Fix PL/PgSQL to handle `var := var` correctly when the variable is of pass-by-reference type
- Update `contrib/tsearch2` to use current Snowball code

## E.50. Release 7.4.8

**Release date:** 2005-05-09

This release contains a variety of fixes from 7.4.7, including several security-related issues.

### E.50.1. Migration to Version 7.4.8

A dump/restore is not required for those running 7.4.X. However, it is one possible way of handling two significant security problems that have been found in the initial contents of 7.4.X system catalogs. A dump/initdb/reload sequence using 7.4.8's initdb will automatically correct these problems.

The larger security problem is that the built-in character set encoding conversion functions can be invoked from SQL commands by unprivileged users, but the functions were not designed for such use and are not secure against malicious choices of arguments. The fix involves changing the declared parameter list of these functions so that they can no longer be invoked from SQL commands. (This does not affect their normal use by the encoding conversion machinery.)

The lesser problem is that the contrib/tsearch2 module creates several functions that are misdeclared to return `internal` when they do not accept `internal` arguments. This breaks type safety for all functions using `internal` arguments.

It is strongly recommended that all installations repair these errors, either by initdb or by following the manual repair procedures given below. The errors at least allow unprivileged database users to crash their server process, and might allow unprivileged users to gain the privileges of a database superuser.

If you wish not to do an initdb, perform the following procedures instead. As the database superuser, do:

```
BEGIN;
UPDATE pg_proc SET proargtypes[3] = 'internal'::regtype
WHERE pronamespace = 11 AND pronargs = 5
    AND proargtypes[2] = 'cstring'::regtype;
-- The command should report having updated 90 rows;
-- if not, rollback and investigate instead of committing!
COMMIT;
```

Next, if you have installed contrib/tsearch2, do:

```
BEGIN;
UPDATE pg_proc SET proargtypes[0] = 'internal'::regtype
WHERE oid IN (
    'dex_init(text)'::regprocedure,
    'snb_en_init(text)'::regprocedure,
    'snb_ru_init(text)'::regprocedure,
    'spell_init(text)'::regprocedure,
    'syn_init(text)'::regprocedure
);
-- The command should report having updated 5 rows;
-- if not, rollback and investigate instead of committing!
COMMIT;
```

If this command fails with a message like “function “dex\_init(text)” does not exist”, then either `tsearch2` is not installed in this database, or you already did the update.

The above procedures must be carried out in *each* database of an installation, including `template1`, and ideally including `template0` as well. If you do not fix the template databases then any subsequently created databases will contain the same errors. `template1` can be fixed in the same way as any other database, but fixing `template0` requires additional steps. First, from any database issue:

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
```

Next connect to `template0` and perform the above repair procedures. Finally, do:

```
-- re-freeze template0:
VACUUM FREEZE;
-- and protect it against future alterations:
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

## E.50.2. Changes

- Change encoding function signature to prevent misuse
- Change `contrib/tsearch2` to avoid unsafe use of `INTERNAL` function results
- Repair ancient race condition that allowed a transaction to be seen as committed for some purposes (eg `SELECT FOR UPDATE`) slightly sooner than for other purposes

This is an extremely serious bug since it could lead to apparent data inconsistencies being briefly visible to applications.

- Repair race condition between relation extension and `VACUUM`

This could theoretically have caused loss of a page’s worth of freshly-inserted data, although the scenario seems of very low probability. There are no known cases of it having caused more than an Assert failure.

- Fix comparisons of `TIME WITH TIME ZONE` values

The comparison code was wrong in the case where the `--enable-integer-datetimes` configuration switch had been used. NOTE: if you have an index on a `TIME WITH TIME ZONE` column, it will need to be `REINDEXED` after installing this update, because the fix corrects the sort order of column values.

- Fix `EXTRACT(EPOCH)` for `TIME WITH TIME ZONE` values
- Fix mis-display of negative fractional seconds in `INTERVAL` values

This error only occurred when the `--enable-integer-datetimes` configuration switch had been used.

- Ensure operations done during backend shutdown are counted by statistics collector

This is expected to resolve reports of `pg_autovacuum` not vacuuming the system catalogs often enough — it was not being told about catalog deletions caused by temporary table removal during backend exit.

- Additional buffer overrun checks in plpgsql (Neil)
- Fix `pg_dump` to dump trigger names containing % correctly (Neil)
- Fix `contrib/pgcrypto` for newer OpenSSL builds (Marko Kreen)
- Still more 64-bit fixes for `contrib/intagg`
- Prevent incorrect optimization of functions returning `RECORD`
- Prevent `to_char(interval)` from dumping core for month-related formats
- Prevent crash on `COALESCE(NULL, NULL)`
- Fix `array_map` to call PL functions correctly
- Fix permission checking in `ALTER DATABASE RENAME`
- Fix `ALTER LANGUAGE RENAME`
- Make `RemoveFromWaitQueue` clean up after itself

This fixes a lock management error that would only be visible if a transaction was kicked out of a wait for a lock (typically by query cancel) and then the holder of the lock released it within a very narrow window.

- Fix problem with untyped parameter appearing in `INSERT ... SELECT`
- Fix `CLUSTER` failure after `ALTER TABLE SET WITHOUT OIDS`

## E.51. Release 7.4.7

**Release date:** 2005-01-31

This release contains a variety of fixes from 7.4.6, including several security-related issues.

### E.51.1. Migration to Version 7.4.7

A dump/restore is not required for those running 7.4.X.

### E.51.2. Changes

- Disallow `LOAD` to non-superusers

On platforms that will automatically execute initialization functions of a shared library (this includes at least Windows and ELF-based Unixen), `LOAD` can be used to make the server execute arbitrary code. Thanks to NGS Software for reporting this.

- Check that creator of an aggregate function has the right to execute the specified transition functions

This oversight made it possible to bypass denial of `EXECUTE` permission on a function.

- Fix security and 64-bit issues in contrib/intagg
- Add needed STRICT marking to some contrib functions (Kris Jurka)
- Avoid buffer overrun when plpgsql cursor declaration has too many parameters (Neil)
- Fix planning error for FULL and RIGHT outer joins

The result of the join was mistakenly supposed to be sorted the same as the left input. This could not only deliver mis-sorted output to the user, but in case of nested merge joins could give outright wrong answers.

- Fix plperl for quote marks in tuple fields
- Fix display of negative intervals in SQL and GERMAN datestyles
- Make age(timestampz) do calculation in local timezone not GMT

## E.52. Release 7.4.6

**Release date:** 2004-10-22

This release contains a variety of fixes from 7.4.5.

### E.52.1. Migration to Version 7.4.6

A dump/restore is not required for those running 7.4.X.

### E.52.2. Changes

- Repair possible failure to update hint bits on disk

Under rare circumstances this oversight could lead to “could not access transaction status” failures, which qualifies it as a potential-data-loss bug.

- Ensure that hashed outer join does not miss tuples

Very large left joins using a hash join plan could fail to output unmatched left-side rows given just the right data distribution.

- Disallow running pg\_ctl as root

This is to guard against any possible security issues.

- Avoid using temp files in /tmp in make\_oidjoins\_check

This has been reported as a security issue, though it’s hardly worthy of concern since there is no reason for non-developers to use this script anyway.

- Prevent forced backend shutdown from re-emitting prior command result

In rare cases, a client might think that its last command had succeeded when it really had been aborted by forced database shutdown.

- Repair bug in `pg_stat_get_backend_idset`

This could lead to misbehavior in some of the system-statistics views.

- Fix small memory leak in postmaster
- Fix “expected both swapped tables to have TOAST tables” bug

This could arise in cases such as `CLUSTER` after `ALTER TABLE DROP COLUMN`.

- Prevent `pg_ctl restart` from adding `-D` multiple times
- Fix problem with NULL values in GiST indexes
- `::` is no longer interpreted as a variable in an ECPG prepare statement

## E.53. Release 7.4.5

**Release date:** 2004-08-18

This release contains one serious bug fix over 7.4.4.

### E.53.1. Migration to Version 7.4.5

A dump/restore is not required for those running 7.4.X.

### E.53.2. Changes

- Repair possible crash during concurrent B-tree index insertions

This patch fixes a rare case in which concurrent insertions into a B-tree index could result in a server panic. No permanent damage would result, but it’s still worth a re-release. The bug does not exist in pre-7.4 releases.

## E.54. Release 7.4.4

**Release date:** 2004-08-16

This release contains a variety of fixes from 7.4.3.

### E.54.1. Migration to Version 7.4.4

A dump/restore is not required for those running 7.4.X.

### E.54.2. Changes

- Prevent possible loss of committed transactions during crash

Due to insufficient interlocking between transaction commit and checkpointing, it was possible for transactions committed just before the most recent checkpoint to be lost, in whole or in part, following a database crash and restart. This is a serious bug that has existed since PostgreSQL 7.1.

- Check HAVING restriction before evaluating result list of an aggregate plan
- Avoid crash when session's current user ID is deleted
- Fix hashed crosstab for zero-rows case (Joe)
- Force cache update after renaming a column in a foreign key
- Pretty-print UNION queries correctly
- Make psql handle `\r\n` newlines properly in COPY IN
- pg\_dump handled ACLs with grant options incorrectly
- Fix thread support for OS X and Solaris
- Updated JDBC driver (build 215) with various fixes
- ECPG fixes
- Translation updates (various contributors)

## E.55. Release 7.4.3

**Release date:** 2004-06-14

This release contains a variety of fixes from 7.4.2.

### E.55.1. Migration to Version 7.4.3

A dump/restore is not required for those running 7.4.X.

### E.55.2. Changes

- Fix temporary memory leak when using non-hashed aggregates (Tom)

- ECPG fixes, including some for Informix compatibility (Michael)
- Fixes for compiling with thread-safety, particularly Solaris (Bruce)
- Fix error in COPY IN termination when using the old network protocol (ljb)
- Several important fixes in `pg_autovacuum`, including fixes for large tables, unsigned oids, stability, temp tables, and debug mode (Matthew T. O'Connor)
- Fix problem with reading tar-format dumps on NetBSD and BSD/OS (Bruce)
- Several JDBC fixes
- Fix ALTER SEQUENCE RESTART where `last_value` equals the restart value (Tom)
- Repair failure to recalculate nested sub-selects (Tom)
- Fix problems with non-constant expressions in LIMIT/OFFSET
- Support FULL JOIN with no join clause, such as `X FULL JOIN Y ON TRUE` (Tom)
- Fix another zero-column table bug (Tom)
- Improve handling of non-qualified identifiers in GROUP BY clauses in sub-selects (Tom)  
Select-list aliases within the sub-select will now take precedence over names from outer query levels.
- Do not generate “NATURAL CROSS JOIN” when decompiling rules (Tom)
- Add checks for invalid field length in binary COPY (Tom)  
This fixes a difficult-to-exploit security hole.
- Avoid locking conflict between `ANALYZE` and `LISTEN/NOTIFY`
- Numerous translation updates (various contributors)

## E.56. Release 7.4.2

**Release date:** 2004-03-08

This release contains a variety of fixes from 7.4.1.

### E.56.1. Migration to Version 7.4.2

A dump/restore is not required for those running 7.4.X. However, it might be advisable as the easiest method of incorporating fixes for two errors that have been found in the initial contents of 7.4.X system catalogs. A dump/initdb/reload sequence using 7.4.2's initdb will automatically correct these problems.

The more severe of the two errors is that data type `anyarray` has the wrong alignment label; this is a problem because the `pg_statistic` system catalog uses `anyarray` columns. The mislabeling can cause planner misestimations and even crashes when planning queries that involve `WHERE` clauses on double-aligned columns (such as `float8` and `timestamp`). It is strongly recommended that all installations repair this error, either by initdb or by following the manual repair procedure given below.

The lesser error is that the system view `pg_settings` ought to be marked as having public update access, to allow `UPDATE pg_settings` to be used as a substitute for `SET`. This can also be fixed either by `initdb` or manually, but it is not necessary to fix unless you want to use `UPDATE pg_settings`.

If you wish not to do an `initdb`, the following procedure will work for fixing `pg_statistic`. As the database superuser, do:

```
-- clear out old data in pg_statistic:
DELETE FROM pg_statistic;
VACUUM pg_statistic;
-- this should update 1 row:
UPDATE pg_type SET typalign = 'd' WHERE oid = 2277;
-- this should update 6 rows:
UPDATE pg_attribute SET attalign = 'd' WHERE atttypid = 2277;
--
-- At this point you MUST start a fresh backend to avoid a crash!
--
-- repopulate pg_statistic:
ANALYZE;
```

This can be done in a live database, but beware that all backends running in the altered database must be restarted before it is safe to repopulate `pg_statistic`.

To repair the `pg_settings` error, simply do:

```
GRANT SELECT, UPDATE ON pg_settings TO PUBLIC;
```

The above procedures must be carried out in *each* database of an installation, including `template1`, and ideally including `template0` as well. If you do not fix the template databases then any subsequently created databases will contain the same errors. `template1` can be fixed in the same way as any other database, but fixing `template0` requires additional steps. First, from any database issue:

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
```

Next connect to `template0` and perform the above repair procedures. Finally, do:

```
-- re-freeze template0:
VACUUM FREEZE;
-- and protect it against future alterations:
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

## E.56.2. Changes

Release 7.4.2 incorporates all the fixes included in release 7.3.6, plus the following fixes:

- Fix `pg_statistics` alignment bug that could crash optimizer  
See above for details about this problem.

- Allow non-super users to update `pg_settings`
- Fix several optimizer bugs, most of which led to “variable not found in subplan target lists” errors
- Avoid out-of-memory failure during startup of large multiple index scan
- Fix multibyte problem that could lead to “out of memory” error during `COPY IN`
- Fix problems with `SELECT INTO / CREATE TABLE AS` from tables without OIDs
- Fix problems with `alter_table` regression test during parallel testing
- Fix problems with hitting open file limit, especially on OS X (Tom)
- Partial fix for Turkish-locale issues  
`initdb` will succeed now in Turkish locale, but there are still some inconveniences associated with the `i/I` problem.
- Make `pg_dump` set client encoding on restore
- Other minor `pg_dump` fixes
- Allow `ecpg` to again use C keywords as column names (Michael)
- Added `ecpg WHENEVER NOT_FOUND` to `SELECT/INSERT/UPDATE/DELETE` (Michael)
- Fix `ecpg` crash for queries calling set-returning functions (Michael)
- Various other `ecpg` fixes (Michael)
- Fixes for Borland compiler
- Thread build improvements (Bruce)
- Various other build fixes
- Various JDBC fixes

## E.57. Release 7.4.1

**Release date:** 2003-12-22

This release contains a variety of fixes from 7.4.

### E.57.1. Migration to Version 7.4.1

A dump/restore is *not* required for those running 7.4.

If you want to install the fixes in the information schema you need to reload it into the database. This is either accomplished by initializing a new cluster by running `initdb`, or by running the following sequence of SQL commands in each database (ideally including `template1`) as a superuser in `psql`, after installing the new release:

```
DROP SCHEMA information_schema CASCADE;
```

```
\i /usr/local/pgsql/share/information_schema.sql
```

Substitute your installation path in the second command.

## E.57.2. Changes

- Fixed bug in `CREATE SCHEMA` parsing in ECPG (Michael)
- Fix compile error when `--enable-thread-safety` and `--with-perl` are used together (Peter)
- Fix for subqueries that used hash joins (Tom)

Certain subqueries that used hash joins would crash because of improperly shared structures.

- Fix free space map compaction bug (Tom)

This fixes a bug where compaction of the free space map could lead to a database server shutdown.

- Fix for Borland compiler build of libpq (Bruce)
- Fix `netmask()` and `hostmask()` to return the maximum-length masklen (Tom)

Fix these functions to return values consistent with pre-7.4 releases.

- Several `contrib/pg_autovacuum` fixes

Fixes include improper variable initialization, missing vacuum after `TRUNCATE`, and duration computation overflow for long vacuums.

- Allow compile of `contrib/cube` under Cygwin (Jason Tishler)
- Fix Solaris use of password file when no passwords are defined (Tom)

Fix crash on Solaris caused by use of any type of password authentication when no passwords were defined.

- JDBC fix for thread problems, other fixes
- Fix for `bytea` index lookups (Joe)
- Fix information schema for bit data types (Peter)
- Force `zero_damaged_pages` to be on during recovery from WAL
- Prevent some obscure cases of “variable not in subplan target lists”
- Make `PQescapeBytea` and `byteaout` consistent with each other (Joe)
- Escape `bytea` output for bytes  $> 0x7e$  (Joe)

If different client encodings are used for `bytea` output and input, it is possible for `bytea` values to be corrupted by the differing encodings. This fix escapes all bytes that might be affected.

- Added missing `SPI_finish()` calls to `dblink`’s `get_tuple_of_interest()` (Joe)
- New Czech FAQ
- Fix information schema view `constraint_column_usage` for foreign keys (Peter)
- ECPG fixes (Michael)
- Fix bug with multiple `IN` subqueries and joins in the subqueries (Tom)

- Allow `COUNT ('x')` to work (Tom)
- Install ECPG include files for Informix compatibility into separate directory (Peter)  
Some names of ECPG include files for Informix compatibility conflicted with operating system include files. By installing them in their own directory, name conflicts have been reduced.
- Fix SSL memory leak (Neil)  
This release fixes a bug in 7.4 where SSL didn't free all memory it allocated.
- Prevent `pg_service.conf` from using service name as default dbname (Bruce)
- Fix local ident authentication on FreeBSD (Tom)

## E.58. Release 7.4

**Release date:** 2003-11-17

### E.58.1. Overview

Major changes in this release:

`IN / NOT IN` subqueries are now much more efficient

In previous releases, `IN/NOT IN` subqueries were joined to the upper query by sequentially scanning the subquery looking for a match. The 7.4 code uses the same sophisticated techniques used by ordinary joins and so is much faster. An `IN` will now usually be as fast as or faster than an equivalent `EXISTS` subquery; this reverses the conventional wisdom that applied to previous releases.

Improved `GROUP BY` processing by using hash buckets

In previous releases, rows to be grouped had to be sorted first. The 7.4 code can do `GROUP BY` without sorting, by accumulating results into a hash table with one entry per group. It will still use the sort technique, however, if the hash table is estimated to be too large to fit in `sort_mem`.

New multikey hash join capability

In previous releases, hash joins could only occur on single keys. This release allows multicolumn hash joins.

Queries using the explicit `JOIN` syntax are now better optimized

Prior releases evaluated queries using the explicit `JOIN` syntax only in the order implied by the syntax. 7.4 allows full optimization of these queries, meaning the optimizer considers all possible join orderings and chooses the most efficient. Outer joins, however, must still follow the declared ordering.

#### Faster and more powerful regular expression code

The entire regular expression module has been replaced with a new version by Henry Spencer, originally written for Tcl. The code greatly improves performance and supports several flavors of regular expressions.

#### Function-inlining for simple SQL functions

Simple SQL functions can now be inlined by including their SQL in the main query. This improves performance by eliminating per-call overhead. That means simple SQL functions now behave like macros.

#### Full support for IPv6 connections and IPv6 address data types

Previous releases allowed only IPv4 connections, and the IP data types only supported IPv4 addresses. This release adds full IPv6 support in both of these areas.

#### Major improvements in SSL performance and reliability

Several people very familiar with the SSL API have overhauled our SSL code to improve SSL key negotiation and error recovery.

#### Make free space map efficiently reuse empty index pages, and other free space management improvements

In previous releases, B-tree index pages that were left empty because of deleted rows could only be reused by rows with index values similar to the rows originally indexed on that page. In 7.4, `VACUUM` records empty index pages and allows them to be reused for any future index rows.

#### SQL-standard information schema

The information schema provides a standardized and stable way to access information about the schema objects defined in a database.

#### Cursors conform more closely to the SQL standard

The commands `FETCH` and `MOVE` have been overhauled to conform more closely to the SQL standard.

#### Cursors can exist outside transactions

These cursors are also called holdable cursors.

#### New client-to-server protocol

The new protocol adds error codes, more status information, faster startup, better support for binary data transmission, parameter values separated from SQL commands, prepared statements available at the protocol level, and cleaner recovery from `COPY` failures. The older protocol is still supported by both server and clients.

#### libpq and ECPG applications are now fully thread-safe

While previous libpq releases already supported threads, this release improves thread safety by fixing some non-thread-safe code that was used during database connection startup. The `configure` option `--enable-thread-safety` must be used to enable this feature.

#### New version of full-text indexing

A new full-text indexing suite is available in `contrib/tsearch2`.

#### New autovacuum tool

The new autovacuum tool in `contrib/autovacuum` monitors the database statistics tables for `INSERT/UPDATE/DELETE` activity and automatically vacuums tables when needed.

Array handling has been improved and moved into the server core

Many array limitations have been removed, and arrays behave more like fully-supported data types.

## E.58.2. Migration to Version 7.4

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

Observe the following incompatibilities:

- The server-side autocommit setting was removed and reimplemented in client applications and languages. Server-side autocommit was causing too many problems with languages and applications that wanted to control their own autocommit behavior, so autocommit was removed from the server and added to individual client APIs as appropriate.
- Error message wording has changed substantially in this release. Significant effort was invested to make the messages more consistent and user-oriented. If your applications try to detect different error conditions by parsing the error message, you are strongly encouraged to use the new error code facility instead.
- Inner joins using the explicit `JOIN` syntax might behave differently because they are now better optimized.
- A number of server configuration parameters have been renamed for clarity, primarily those related to logging.
- `FETCH 0` or `MOVE 0` now does nothing. In prior releases, `FETCH 0` would fetch all remaining rows, and `MOVE 0` would move to the end of the cursor.
- `FETCH` and `MOVE` now return the actual number of rows fetched/moved, or zero if at the beginning/end of the cursor. Prior releases would return the row count passed to the command, not the number of rows actually fetched or moved.
- `COPY` now can process files that use carriage-return or carriage-return/line-feed end-of-line sequences. Literal carriage-returns and line-feeds are no longer accepted in data values; use `\r` and `\n` instead.
- Trailing spaces are now trimmed when converting from type `char(n)` to `varchar(n)` or `text`. This is what most people always expected to happen anyway.
- The data type `float(p)` now measures *p* in binary digits, not decimal digits. The new behavior follows the SQL standard.
- Ambiguous date values now must match the ordering specified by the `datestyle` setting. In prior releases, a date specification of `10/20/03` was interpreted as a date in October even if `datestyle` specified that the day should be first. 7.4 will throw an error if a date specification is invalid for the current setting of `datestyle`.
- The functions `oidrand`, `oidsrand`, and `userfntest` have been removed. These functions were determined to be no longer useful.
- String literals specifying time-varying date/time values, such as `'now'` or `'today'` will no longer work as expected in column default expressions; they now cause the time of the table creation to be the default, not the time of the insertion. Functions such as `now()`, `current_timestamp`, or `current_date` should be used instead.

In previous releases, there was special code so that strings such as `'now'` were interpreted at `INSERT` time and not at table creation time, but this work around didn't cover all cases. Release 7.4 now requires that defaults be defined properly using functions such as `now()` or `current_timestamp`. These will work in all situations.

- The dollar sign (\$) is no longer allowed in operator names. It can instead be a non-first character in identifiers. This was done to improve compatibility with other database systems, and to avoid syntax problems when parameter placeholders (`$n`) are written adjacent to operators.

## E.58.3. Changes

Below you will find a detailed account of the changes between release 7.4 and the previous major release.

### E.58.3.1. Server Operation Changes

- Allow IPv6 server connections (Nigel Kukard, Johan Jordaan, Bruce, Tom, Kurt Roeckx, Andrew Dunstan)
- Fix SSL to handle errors cleanly (Nathan Mueller)  
In prior releases, certain SSL API error reports were not handled correctly. This release fixes those problems.
- SSL protocol security and performance improvements (Sean Chittenden)  
SSL key renegotiation was happening too frequently, causing poor SSL performance. Also, initial key handling was improved.
- Print lock information when a deadlock is detected (Tom)  
This allows easier debugging of deadlock situations.
- Update `/tmp` socket modification times regularly to avoid their removal (Tom)  
This should help prevent `/tmp` directory cleaner administration scripts from removing server socket files.
- Enable PAM for Mac OS X (Aaron Hillegass)
- Make B-tree indexes fully WAL-safe (Tom)  
In prior releases, under certain rare cases, a server crash could cause B-tree indexes to become corrupt. This release removes those last few rare cases.
- Allow B-tree index compaction and empty page reuse (Tom)
- Fix inconsistent index lookups during split of first root page (Tom)  
In prior releases, when a single-page index split into two pages, there was a brief period when another database session could miss seeing an index entry. This release fixes that rare failure case.
- Improve free space map allocation logic (Tom)
- Preserve free space information between server restarts (Tom)

In prior releases, the free space map was not saved when the postmaster was stopped, so newly started servers had no free space information. This release saves the free space map, and reloads it when the server is restarted.

- Add start time to `pg_stat_activity` (Neil)
- New code to detect corrupt disk pages; erase with `zero_damaged_pages` (Tom)
- New client/server protocol: faster, no username length limit, allow clean exit from `COPY` (Tom)
- Add transaction status, table ID, column ID to client/server protocol (Tom)
- Add binary I/O to client/server protocol (Tom)
- Remove autocommit server setting; move to client applications (Tom)
- New error message wording, error codes, and three levels of error detail (Tom, Joe, Peter)

### E.58.3.2. Performance Improvements

- Add hashing for `GROUP BY` aggregates (Tom)
- Make nested-loop joins be smarter about multicolumn indexes (Tom)
- Allow multikey hash joins (Tom)
- Improve constant folding (Tom)
- Add ability to inline simple SQL functions (Tom)
- Reduce memory usage for queries using complex functions (Tom)

In prior releases, functions returning allocated memory would not free it until the query completed. This release allows the freeing of function-allocated memory when the function call completes, reducing the total memory used by functions.

- Improve GEQO optimizer performance (Tom)

This release fixes several inefficiencies in the way the GEQO optimizer manages potential query paths.

- Allow `IN/NOT IN` to be handled via hash tables (Tom)
- Improve `NOT IN (subquery)` performance (Tom)
- Allow most `IN` subqueries to be processed as joins (Tom)
- Pattern matching operations can use indexes regardless of locale (Peter)

There is no way for non-ASCII locales to use the standard indexes for `LIKE` comparisons. This release adds a way to create a special index for `LIKE`.

- Allow the postmaster to preload libraries using `preload_libraries` (Joe)

For shared libraries that require a long time to load, this option is available so the library can be preloaded in the postmaster and inherited by all database sessions.

- Improve optimizer cost computations, particularly for subqueries (Tom)
- Avoid sort when subquery `ORDER BY` matches upper query (Tom)
- Deduce that `WHERE a.x = b.y AND b.y = 42` also means `a.x = 42` (Tom)

- Allow hash/merge joins on complex joins (Tom)
- Allow hash joins for more data types (Tom)
- Allow join optimization of explicit inner joins, disable with `join_collapse_limit` (Tom)
- Add parameter `from_collapse_limit` to control conversion of subqueries to joins (Tom)
- Use faster and more powerful regular expression code from Tcl (Henry Spencer, Tom)
- Use bit-mapped relation sets in the optimizer (Tom)
- Improve connection startup time (Tom)

The new client/server protocol requires fewer network packets to start a database session.

- Improve trigger/constraint performance (Stephan)
- Improve speed of `col IN (const, const, const, ...)` (Tom)
- Fix hash indexes which were broken in rare cases (Tom)
- Improve hash index concurrency and speed (Tom)

Prior releases suffered from poor hash index performance, particularly for high concurrency situations. This release fixes that, and the development group is interested in reports comparing B-tree and hash index performance.

- Align shared buffers on 32-byte boundary for copy speed improvement (Manfred Spraul)

Certain CPU's perform faster data copies when addresses are 32-byte aligned.

- Data type `numeric` reimplemented for better performance (Tom)

`numeric` used to be stored in base 100. The new code uses base 10000, for significantly better performance.

### E.58.3.3. Server Configuration Changes

- Rename server parameter `server_min_messages` to `log_min_messages` (Bruce)

This was done so most parameters that control the server logs begin with `log_`.

- Rename `show_*_stats` to `log_*_stats` (Bruce)
- Rename `show_source_port` to `log_source_port` (Bruce)
- Rename `hostname_lookup` to `log_hostname` (Bruce)
- Add `checkpoint_warning` to warn of excessive checkpointing (Bruce)

In prior releases, it was difficult to determine if checkpoint was happening too frequently. This feature adds a warning to the server logs when excessive checkpointing happens.

- New read-only server parameters for localization (Tom)
- Change debug server log messages to output as `DEBUG` rather than `LOG` (Bruce)
- Prevent server log variables from being turned off by non-superusers (Bruce)

This is a security feature so non-superusers cannot disable logging that was enabled by the administrator.

- `log_min_messages/client_min_messages` now controls `debug_*` output (Bruce)  
This centralizes client debug information so all debug output can be sent to either the client or server logs.
- Add Mac OS X Rendezvous server support (Chris Campbell)  
This allows Mac OS X hosts to query the network for available PostgreSQL servers.
- Add ability to print only slow statements using `log_min_duration_statement` (Christopher)  
This is an often requested debugging feature that allows administrators to see only slow queries in their server logs.
- Allow `pg_hba.conf` to accept netmasks in CIDR format (Andrew Dunstan)  
This allows administrators to merge the host IP address and netmask fields into a single CIDR field in `pg_hba.conf`.
- New read-only parameter `is_superuser` (Tom)
- New parameter `log_error_verbosity` to control error detail (Tom)  
This works with the new error reporting feature to supply additional error information like hints, file names and line numbers.
- `postgres --describe-config` now dumps server config variables (Aizaz Ahmed, Peter)  
This option is useful for administration tools that need to know the configuration variable names and their minimums, maximums, defaults, and descriptions.
- Add new columns in `pg_settings`: `context`, `type`, `source`, `min_val`, `max_val` (Joe)
- Make default `shared_buffers` 1000 and `max_connections` 100, if possible (Tom)  
Prior versions defaulted to 64 shared buffers so PostgreSQL would start on even very old systems. This release tests the amount of shared memory allowed by the platform and selects more reasonable default values if possible. Of course, users are still encouraged to evaluate their resource load and size `shared_buffers` accordingly.
- New `pg_hba.conf` record type `hostnossl` to prevent SSL connections (Jon Jensen)  
In prior releases, there was no way to prevent SSL connections if both the client and server supported SSL. This option allows that capability.
- Remove parameter `geqo_random_seed` (Tom)
- Add server parameter `regex_flavor` to control regular expression processing (Tom)
- Make `pg_ctl` better handle nonstandard ports (Greg)

### E.58.3.4. Query Changes

- New SQL-standard information schema (Peter)
- Add read-only transactions (Peter)
- Print key name and value in foreign-key violation messages (Dmitry Tkach)
- Allow users to see their own queries in `pg_stat_activity` (Kevin Brown)

In prior releases, only the superuser could see query strings using `pg_stat_activity`. Now ordinary users can see their own query strings.

- Fix aggregates in subqueries to match SQL standard (Tom)

The SQL standard says that an aggregate function appearing within a nested subquery belongs to the outer query if its argument contains only outer-query variables. Prior PostgreSQL releases did not handle this fine point correctly.

- Add option to prevent auto-addition of tables referenced in query (Nigel J. Andrews)

By default, tables mentioned in the query are automatically added to the `FROM` clause if they are not already there. This is compatible with historic POSTGRES behavior but is contrary to the SQL standard. This option allows selecting standard-compatible behavior.

- Allow `UPDATE ... SET col = DEFAULT` (Rod)

This allows `UPDATE` to set a column to its declared default value.

- Allow expressions to be used in `LIMIT/OFFSET` (Tom)

In prior releases, `LIMIT/OFFSET` could only use constants, not expressions.

- Implement `CREATE TABLE AS EXECUTE` (Neil, Peter)

### E.58.3.5. Object Manipulation Changes

- Make `CREATE SEQUENCE` grammar more conforming to SQL:2003 (Neil)

- Add statement-level triggers (Neil)

While this allows a trigger to fire at the end of a statement, it does not allow the trigger to access all rows modified by the statement. This capability is planned for a future release.

- Add check constraints for domains (Rod)

This greatly increases the usefulness of domains by allowing them to use check constraints.

- Add `ALTER DOMAIN` (Rod)

This allows manipulation of existing domains.

- Fix several zero-column table bugs (Tom)

PostgreSQL supports zero-column tables. This fixes various bugs that occur when using such tables.

- Have `ALTER TABLE ... ADD PRIMARY KEY` add not-null constraint (Rod)

In prior releases, `ALTER TABLE ... ADD PRIMARY` would add a unique index, but not a not-null constraint. That is fixed in this release.

- Add `ALTER TABLE ... WITHOUT OIDS` (Rod)

This allows control over whether new and updated rows will have an OID column. This is most useful for saving storage space.

- Add `ALTER SEQUENCE` to modify minimum, maximum, increment, cache, cycle values (Rod)

- Add `ALTER TABLE ... CLUSTER ON` (Alvaro Herrera)

This command is used by `pg_dump` to record the cluster column for each table previously clustered. This information is used by database-wide cluster to cluster all previously clustered tables.

- Improve automatic type casting for domains (Rod, Tom)
- Allow dollar signs in identifiers, except as first character (Tom)
- Disallow dollar signs in operator names, so `x=$1` works (Tom)
- Allow copying table schema using `LIKE subtable`, also SQL:2003 feature `INCLUDING DEFAULTS` (Rod)
- Add `WITH GRANT OPTION` clause to `GRANT` (Peter)

This enabled `GRANT` to give other users the ability to grant privileges on a object.

### E.58.3.6. Utility Command Changes

- Add `ON COMMIT` clause to `CREATE TABLE` for temporary tables (Gavin)

This adds the ability for a table to be dropped or all rows deleted on transaction commit.

- Allow cursors outside transactions using `WITH HOLD` (Neil)

In previous releases, cursors were removed at the end of the transaction that created them. Cursors can now be created with the `WITH HOLD` option, which allows them to continue to be accessed after the creating transaction has committed.

- `FETCH 0` and `MOVE 0` now do nothing (Bruce)

In previous releases, `FETCH 0` fetched all remaining rows, and `MOVE 0` moved to the end of the cursor.

- Cause `FETCH` and `MOVE` to return the number of rows fetched/moved, or zero if at the beginning/end of cursor, per SQL standard (Bruce)

In prior releases, the row count returned by `FETCH` and `MOVE` did not accurately reflect the number of rows processed.

- Properly handle `SCROLL` with cursors, or report an error (Neil)

Allowing random access (both forward and backward scrolling) to some kinds of queries cannot be done without some additional work. If `SCROLL` is specified when the cursor is created, this additional work will be performed. Furthermore, if the cursor has been created with `NO SCROLL`, no random access is allowed.

- Implement SQL-compatible options `FIRST`, `LAST`, `ABSOLUTE n`, `RELATIVE n` for `FETCH` and `MOVE` (Tom)
- Allow `EXPLAIN` on `DECLARE CURSOR` (Tom)
- Allow `CLUSTER` to use index marked as pre-clustered by default (Alvaro Herrera)
- Allow `CLUSTER` to cluster all tables (Alvaro Herrera)

This allows all previously clustered tables in a database to be reclustered with a single command.

- Prevent `CLUSTER` on partial indexes (Tom)
- Allow DOS and Mac line-endings in `COPY` files (Bruce)

- Disallow literal carriage return as a data value, backslash-carriage-return and `\r` are still allowed (Bruce)
- `COPY` changes (binary, `\.`) (Tom)
- Recover from `COPY` failure cleanly (Tom)
- Prevent possible memory leaks in `COPY` (Tom)
- Make `TRUNCATE` transaction-safe (Rod)

`TRUNCATE` can now be used inside a transaction. If the transaction aborts, the changes made by the `TRUNCATE` are automatically rolled back.

- Allow prepare/bind of utility commands like `FETCH` and `EXPLAIN` (Tom)
- Add `EXPLAIN EXECUTE` (Neil)
- Improve `VACUUM` performance on indexes by reducing WAL traffic (Tom)
- Functional indexes have been generalized into indexes on expressions (Tom)

In prior releases, functional indexes only supported a simple function applied to one or more column names. This release allows any type of scalar expression.

- Have `SHOW TRANSACTION ISOLATION` match input to `SET TRANSACTION ISOLATION` (Tom)
- Have `COMMENT ON DATABASE` on nonlocal database generate a warning, rather than an error (Rod)

Database comments are stored in database-local tables so comments on a database have to be stored in each database.

- Improve reliability of `LISTEN/NOTIFY` (Tom)
- Allow `REINDEX` to reliably reindex nonshared system catalog indexes (Tom)

This allows system tables to be reindexed without the requirement of a standalone session, which was necessary in previous releases. The only tables that now require a standalone session for reindexing are the global system tables `pg_database`, `pg_shadow`, and `pg_group`.

### E.58.3.7. Data Type and Function Changes

- New server parameter `extra_float_digits` to control precision display of floating-point numbers (Pedro Ferreira, Tom)

This controls output precision which was causing regression testing problems.

- Allow `+1300` as a numeric time-zone specifier, for `FJST` (Tom)
- Remove rarely used functions `oidrand`, `oidsrand`, and `userfntest` functions (Neil)
- Add `md5()` function to main server, already in `contrib/pgcrypto` (Joe)

An MD5 function was frequently requested. For more complex encryption capabilities, use `contrib/pgcrypto`.

- Increase date range of `timestamp` (John Cochran)
- Change `EXTRACT(EPOCH FROM timestamp)` so `timestamp` without time zone is assumed to be in local time, not GMT (Tom)

- Trap division by zero in case the operating system doesn't prevent it (Tom)
- Change the `numeric` data type internally to base 10000 (Tom)
- New `hostmask()` function (Greg Wickham)
- Fixes for `to_char()` and `to_timestamp()` (Karel)
- Allow functions that can take any argument data type and return any data type, using `anyelement` and `anyarray` (Joe)

This allows the creation of functions that can work with any data type.

- Arrays can now be specified as `ARRAY[1,2,3]`, `ARRAY[['a','b'],['c','d']]`, or `ARRAY[ARRAY[ARRAY[2]]]` (Joe)
- Allow proper comparisons for arrays, including `ORDER BY` and `DISTINCT` support (Joe)
- Allow indexes on array columns (Joe)
- Allow array concatenation with `||` (Joe)
- Allow `WHERE` qualification `expr op ANY/SOME/ALL (array_expr)` (Joe)

This allows arrays to behave like a list of values, for purposes like `SELECT * FROM tab WHERE col IN (array_val)`.

- New array functions `array_append`, `array_cat`, `array_lower`, `array_prepend`, `array_to_string`, `array_upper`, `string_to_array` (Joe)
- Allow user defined aggregates to use polymorphic functions (Joe)
- Allow assignments to empty arrays (Joe)
- Allow 60 in seconds fields of `time`, `timestamp`, and `interval` input values (Tom)

Sixty-second values are needed for leap seconds.

- Allow `cidr` data type to be cast to `text` (Tom)
- Disallow invalid time zone names in `SET TIMEZONE`
- Trim trailing spaces when `char` is cast to `varchar` or `text` (Tom)
- Make `float(p)` measure the precision `p` in binary digits, not decimal digits (Tom)
- Add IPv6 support to the `inet` and `cidr` data types (Michael Graff)
- Add `family()` function to report whether address is IPv4 or IPv6 (Michael Graff)
- Have `SHOW datestyle` generate output similar to that used by `SET datestyle` (Tom)
- Make `EXTRACT(TIMEZONE)` and `SET/SHOW TIME ZONE` follow the SQL convention for the sign of time zone offsets, i.e., positive is east from UTC (Tom)
- Fix `date_trunc('quarter', ...)` (Böjthe Zoltán)

Prior releases returned an incorrect value for this function call.

- Make `initcap()` more compatible with Oracle (Mike Nolan)

`initcap()` now uppercases a letter appearing after any non-alphanumeric character, rather than only after whitespace.

- Allow only `datestyle` field order for date values not in ISO-8601 format (Greg)

- Add new `datestyle` values `MDY`, `DMY`, and `YMD` to set input field order; honor `US` and `European` for backward compatibility (Tom)
- String literals like `'now'` or `'today'` will no longer work as a column default. Use functions such as `now()`, `current_timestamp` instead. (change required for prepared statements) (Tom)
- Treat `NaN` as larger than any other value in `min()`/`max()` (Tom)  
`NaN` was already sorted after ordinary numeric values for most purposes, but `min()` and `max()` didn't get this right.
- Prevent interval from suppressing `:00` seconds display
- New functions `pg_get_triggerdef(prettyprint)` and `pg_conversion_is_visible()` (Christopher)
- Allow time to be specified as `040506` or `0405` (Tom)
- Input date order must now be `YYYY-MM-DD` (with 4-digit year) or match `datestyle`
- Make `pg_get_constraintdef` support unique, primary-key, and check constraints (Christopher)

### E.58.3.8. Server-Side Language Changes

- Prevent PL/pgSQL crash when `RETURN NEXT` is used on a zero-row record variable (Tom)
- Make PL/Python's `spi_execute` interface handle null values properly (Andrew Bosma)
- Allow PL/pgSQL to declare variables of composite types without `%ROWTYPE` (Tom)
- Fix PL/Python's `_quote()` function to handle big integers
- Make PL/Python an untrusted language, now called `plpythonu` (Kevin Jacobs, Tom)  
 The Python language no longer supports a restricted execution environment, so the trusted version of PL/Python was removed. If this situation changes, a version of PL/Python that can be used by non-superusers will be readded.
- Allow polymorphic PL/pgSQL functions (Joe, Tom)
- Allow polymorphic SQL functions (Joe)
- Improved compiled function caching mechanism in PL/pgSQL with full support for polymorphism (Joe)
- Add new parameter `$0` in PL/pgSQL representing the function's actual return type (Joe)
- Allow PL/Tcl and PL/Python to use the same trigger on multiple tables (Tom)
- Fixed PL/Tcl's `spi_prepare` to accept fully qualified type names in the parameter type list (Jan)

### E.58.3.9. psql Changes

- Add `\pset pager always` to always use pager (Greg)

This forces the pager to be used even if the number of rows is less than the screen height. This is valuable for rows that wrap across several screen rows.

- Improve tab completion (Rod, Ross Reedstrom, Ian Barwick)
- Reorder `\? help` into groupings (Harald Armin Massa, Bruce)
- Add backslash commands for listing schemas, casts, and conversions (Christopher)
- `\encoding` now changes based on the server parameter `client_encoding` (Tom)

In previous versions, `\encoding` was not aware of encoding changes made using `SET client_encoding`.

- Save editor buffer into readline history (Ross)
 

When `\e` is used to edit a query, the result is saved in the readline history for retrieval using the up arrow.
- Improve `\d display` (Christopher)
- Enhance HTML mode to be more standards-conforming (Greg)
- New `\set AUTOCOMMIT off` capability (Tom)
 

This takes the place of the removed server parameter `autocommit`.
- New `\set VERBOSITY` to control error detail (Tom)
 

This controls the new error reporting details.
- New prompt escape sequence `%x` to show transaction status (Tom)
- Long options for `psql` are now available on all platforms

### E.58.3.10. `pg_dump` Changes

- Multiple `pg_dump` fixes, including tar format and large objects
- Allow `pg_dump` to dump specific schemas (Neil)
- Make `pg_dump` preserve column storage characteristics (Christopher)
 

This preserves `ALTER TABLE ... SET STORAGE` information.
- Make `pg_dump` preserve `CLUSTER` characteristics (Christopher)
- Have `pg_dumpall` use `GRANT/REVOKE` to dump database-level privileges (Tom)
- Allow `pg_dumpall` to support the options `-a`, `-s`, `-x` of `pg_dump` (Tom)
- Prevent `pg_dump` from lowercasing identifiers specified on the command line (Tom)
- `pg_dump` options `--use-set-session-authorization` and `--no-reconnect` now do nothing, all dumps use `SET SESSION AUTHORIZATION`

`pg_dump` no longer reconnects to switch users, but instead always uses `SET SESSION AUTHORIZATION`. This will reduce password prompting during restores.
- Long options for `pg_dump` are now available on all platforms
 

PostgreSQL now includes its own long-option processing routines.

### E.58.3.11. libpq Changes

- Add function `PQfreemem` for freeing memory on Windows, suggested for NOTIFY (Bruce)

Windows requires that memory allocated in a library be freed by a function in the same library, hence `free()` doesn't work for freeing memory allocated by libpq. `PQfreemem` is the proper way to free libpq memory, especially on Windows, and is recommended for other platforms as well.

- Document service capability, and add sample file (Bruce)

This allows clients to look up connection information in a central file on the client machine.

- Make `PQsetdbLogin` have the same defaults as `PQconnectdb` (Tom)
- Allow libpq to cleanly fail when result sets are too large (Tom)
- Improve performance of function `PQunescapeBytea` (Ben Lamb)
- Allow thread-safe libpq with `configure` option `--enable-thread-safety` (Lee Kindness, Philip Yarra)
- Allow function `pqInternalNotice` to accept a format string and arguments instead of just a preformatted message (Tom, Sean Chittenden)
- Control SSL negotiation with `sslmode` values `disable`, `allow`, `prefer`, and `require` (Jon Jensen)
- Allow new error codes and levels of text (Tom)
- Allow access to the underlying table and column of a query result (Tom)  
This is helpful for query-builder applications that want to know the underlying table and column names associated with a specific result set.
- Allow access to the current transaction status (Tom)
- Add ability to pass binary data directly to the server (Tom)
- Add function `PQexecPrepared` and `PQsendQueryPrepared` functions which perform bind/execute of previously prepared statements (Tom)

### E.58.3.12. JDBC Changes

- Allow `setNull` on updateable result sets
- Allow `executeBatch` on a prepared statement (Barry)
- Support SSL connections (Barry)
- Handle schema names in result sets (Paul Sorenson)
- Add refcursor support (Nic Ferrier)

### E.58.3.13. Miscellaneous Interface Changes

- Prevent possible memory leak or core dump during libpqctl shutdown (Tom)
- Add Informix compatibility to ECPG (Michael)

This allows ECPG to process embedded C programs that were written using certain Informix extensions.

- Add type `decimal` to ECPG that is fixed length, for Informix (Michael)
- Allow thread-safe embedded SQL programs with `configure` option `--enable-thread-safety` (Lee Kindness, Bruce)

This allows multiple threads to access the database at the same time.

- Moved Python client PyGreSQL to <http://www.pygresql.org> (Marc)

### E.58.3.14. Source Code Changes

- Prevent need for separate platform geometry regression result files (Tom)
- Improved PPC locking primitive (Reinhard Max)
- New function `palloc0` to allocate and clear memory (Bruce)
- Fix locking code for s390x CPU (64-bit) (Tom)
- Allow OpenBSD to use local ident credentials (William Ahern)
- Make query plan trees read-only to executor (Tom)
- Add Darwin startup scripts (David Wheeler)
- Allow libpq to compile with Borland C++ compiler (Lester Godwin, Karl Waclawek)
- Use our own version of `getopt_long()` if needed (Peter)
- Convert administration scripts to C (Peter)
- Bison `>= 1.85` is now required to build the PostgreSQL grammar, if building from CVS
- Merge documentation into one book (Peter)
- Add Windows compatibility functions (Bruce)
- Allow client interfaces to compile under MinGW (Bruce)
- New `ereport()` function for error reporting (Tom)
- Support Intel compiler on Linux (Peter)
- Improve Linux startup scripts (Slawomir Sudnik, Darko Prenosil)
- Add support for AMD Opteron and Itanium (Jeffrey W. Baker, Bruce)
- Remove `--enable-recode` option from `configure`

This was no longer needed now that we have `CREATE CONVERSION`.

- Generate a compile error if spinlock code is not found (Bruce)

Platforms without spinlock code will now fail to compile, rather than silently using semaphores. This failure can be disabled with a new `configure` option.

### E.58.3.15. Contrib Changes

- Change dbmirror license to BSD
- Improve earthdistance (Bruno Wolff III)
- Portability improvements to pgcrypto (Marko Kreen)
- Prevent crash in xml (John Gray, Michael Richards)
- Update oracle
- Update mysql
- Update cube (Bruno Wolff III)
- Update earthdistance to use cube (Bruno Wolff III)
- Update btree\_gist (Oleg)
- New tsearch2 full-text search module (Oleg, Teodor)
- Add hash-based crosstab function to tablefuncs (Joe)
- Add serial column to order `connectby()` siblings in tablefuncs (Nabil Sayegh, Joe)
- Add named persistent connections to dblink (Shridhar Daithanka)
- New `pg_autovacuum` allows automatic `VACUUM` (Matthew T. O'Connor)
- Make `pgbench` honor environment variables `PGHOST`, `PGPORT`, `PGUSER` (Tatsuo)
- Improve intarray (Teodor Sigaev)
- Improve pgstattuple (Rod)
- Fix bug in `metaphone()` in `fuzzystrmatch`
- Improve adddepend (Rod)
- Update spi/timetravel (Böjthe Zoltán)
- Fix `dbase -s` option and improve non-ASCII handling (Thomas Behr, Márcio Smiderle)
- Remove array module because features now included by default (Joe)

## E.59. Release 7.3.21

**Release date:** 2008-01-07

This release contains a variety of fixes from 7.3.20, including fixes for significant security issues.

This is expected to be the last PostgreSQL release in the 7.3.X series. Users are encouraged to update to a newer release branch soon.

## E.59.1. Migration to Version 7.3.21

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

## E.59.2. Changes

- Prevent functions in indexes from executing with the privileges of the user running `VACUUM`, `ANALYZE`, etc (Tom)

Functions used in index expressions and partial-index predicates are evaluated whenever a new table entry is made. It has long been understood that this poses a risk of trojan-horse code execution if one modifies a table owned by an untrustworthy user. (Note that triggers, defaults, check constraints, etc. pose the same type of risk.) But functions in indexes pose extra danger because they will be executed by routine maintenance operations such as `VACUUM FULL`, which are commonly performed automatically under a superuser account. For example, a nefarious user can execute code with superuser privileges by setting up a trojan-horse index definition and waiting for the next routine vacuum. The fix arranges for standard maintenance operations (including `VACUUM`, `ANALYZE`, `REINDEX`, and `CLUSTER`) to execute as the table owner rather than the calling user, using the same privilege-switching mechanism already used for `SECURITY DEFINER` functions. To prevent bypassing this security measure, execution of `SET SESSION AUTHORIZATION` and `SET ROLE` is now forbidden within a `SECURITY DEFINER` context. (CVE-2007-6600)

- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

The fix that appeared for this in 7.3.20 was incomplete, as it plugged the hole for only some `dblink` functions. (CVE-2007-6601, CVE-2007-3278)

- Fix potential crash in `translate()` when using a multibyte database encoding (Tom)
- Make `contrib/tablefunc`'s `crosstab()` handle `NULL` rowid as a category in its own right, rather than crashing (Joe)
- Require a specific version of Autoconf to be used when re-generating the `configure` script (Peter)

This affects developers and packagers only. The change was made to prevent accidental use of untested combinations of Autoconf and PostgreSQL versions. You can remove the version check if you really want to use a different Autoconf version, but it's your responsibility whether the result works or not.

## E.60. Release 7.3.20

**Release date:** 2007-09-17

This release contains fixes from 7.3.19.

## E.60.1. Migration to Version 7.3.20

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

## E.60.2. Changes

- Prevent index corruption when a transaction inserts rows and then aborts close to the end of a concurrent `VACUUM` on the same table (Tom)
- Make `CREATE DOMAIN ... DEFAULT NULL` work properly (Tom)
- Fix crash when `log_min_error_statement` logging runs out of memory (Tom)
- Require non-superusers who use `/contrib/dblink` to use only password authentication, as a security measure (Joe)

# E.61. Release 7.3.19

**Release date:** 2007-04-23

This release contains fixes from 7.3.18, including a security fix.

## E.61.1. Migration to Version 7.3.19

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

## E.61.2. Changes

- Support explicit placement of the temporary-table schema within `search_path`, and disable searching it for functions and operators (Tom)

This is needed to allow a security-definer function to set a truly secure value of `search_path`. Without it, an unprivileged SQL user can use temporary objects to execute code with the privileges of the security-definer function (CVE-2007-2138). See `CREATE FUNCTION` for more information.

- Fix potential-data-corruption bug in how `VACUUM FULL` handles `UPDATE` chains (Tom, Pavan Deolasee)

## E.62. Release 7.3.18

**Release date:** 2007-02-05

This release contains a variety of fixes from 7.3.17, including a security fix.

### E.62.1. Migration to Version 7.3.18

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

### E.62.2. Changes

- Remove security vulnerability that allowed connected users to read backend memory (Tom)

The vulnerability involves changing the data type of a table column used in a SQL function (CVE-2007-0555). This error can easily be exploited to cause a backend crash, and in principle might be used to read database content that the user should not be able to access.

- Fix rare bug wherein btree index page splits could fail due to choosing an infeasible split point (Heikki Linnakangas)
- Tighten security of multi-byte character processing for UTF8 sequences over three bytes long (Tom)

## E.63. Release 7.3.17

**Release date:** 2007-01-08

This release contains a variety of fixes from 7.3.16.

### E.63.1. Migration to Version 7.3.17

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

## E.63.2. Changes

- `to_number()` and `to_char(numeric)` are now `STABLE`, not `IMMUTABLE`, for new `initdb` installs (Tom)

This is because `lc_numeric` can potentially change the output of these functions.

- Improve index usage of regular expressions that use parentheses (Tom)

This improves `psql \d` performance also.

## E.64. Release 7.3.16

**Release date:** 2006-10-16

This release contains a variety of fixes from 7.3.15.

### E.64.1. Migration to Version 7.3.16

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

### E.64.2. Changes

- Fix corner cases in pattern matching for `psql`'s `\d` commands
- Fix index-corrupting bugs in `/contrib/ltree` (Teodor)
- Back-port 7.4 spinlock code to improve performance and support 64-bit architectures better
- Fix SSL-related memory leak in `libpq`
- Fix backslash escaping in `/contrib/dbmirror`
- Adjust regression tests for recent changes in US DST laws

## E.65. Release 7.3.15

**Release date:** 2006-05-23

This release contains a variety of fixes from 7.3.14, including patches for extremely serious security issues.

## E.65.1. Migration to Version 7.3.15

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

Full security against the SQL-injection attacks described in CVE-2006-2313 and CVE-2006-2314 might require changes in application code. If you have applications that embed untrustworthy strings into SQL commands, you should examine them as soon as possible to ensure that they are using recommended escaping techniques. In most cases, applications should be using subroutines provided by libraries or drivers (such as libpq's `PQescapeStringConn()`) to perform string escaping, rather than relying on *ad hoc* code to do it.

## E.65.2. Changes

- Change the server to reject invalidly-encoded multibyte characters in all cases (Tatsuo, Tom)

While PostgreSQL has been moving in this direction for some time, the checks are now applied uniformly to all encodings and all textual input, and are now always errors not merely warnings. This change defends against SQL-injection attacks of the type described in CVE-2006-2313.

- Reject unsafe uses of `\'` in string literals

As a server-side defense against SQL-injection attacks of the type described in CVE-2006-2314, the server now only accepts `"` and not `\'` as a representation of ASCII single quote in SQL string literals. By default, `\'` is rejected only when `client_encoding` is set to a client-only encoding (SJIS, BIG5, GBK, GB18030, or UHC), which is the scenario in which SQL injection is possible. A new configuration parameter `backslash_quote` is available to adjust this behavior when needed. Note that full security against CVE-2006-2314 might require client-side changes; the purpose of `backslash_quote` is in part to make it obvious that insecure clients are insecure.

- Modify libpq's string-escaping routines to be aware of encoding considerations

This fixes libpq-using applications for the security issues described in CVE-2006-2313 and CVE-2006-2314. Applications that use multiple PostgreSQL connections concurrently should migrate to `PQescapeStringConn()` and `PQescapeByteaConn()` to ensure that escaping is done correctly for the settings in use in each database connection. Applications that do string escaping “by hand” should be modified to rely on library routines instead.

- Fix some incorrect encoding conversion functions

`win1251_to_iso`, `alt_to_iso`, `euc_tw_to_big5`, `euc_tw_to_mic`, `mic_to_euc_tw` were all broken to varying extents.

- Clean up stray remaining uses of `\'` in strings (Bruce, Jan)
- Fix server to use custom DH SSL parameters correctly (Michael Fuhr)
- Fix various minor memory leaks

## E.66. Release 7.3.14

**Release date:** 2006-02-14

This release contains a variety of fixes from 7.3.13.

### E.66.1. Migration to Version 7.3.14

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.13, see the release notes for 7.3.13.

### E.66.2. Changes

- Fix potential crash in `SET SESSION AUTHORIZATION` (CVE-2006-0553)

An unprivileged user could crash the server process, resulting in momentary denial of service to other users, if the server has been compiled with Asserts enabled (which is not the default). Thanks to Akio Ishida for reporting this problem.

- Fix bug with row visibility logic in self-inserted rows (Tom)

Under rare circumstances a row inserted by the current command could be seen as already valid, when it should not be. Repairs bug created in 7.3.11 release.

- Fix race condition that could lead to “file already exists” errors during `pg_clog` file creation (Tom)
- Fix to allow restoring dumps that have cross-schema references to custom operators (Tom)
- Portability fix for testing presence of `finite` and `isinf` during configure (Tom)

## E.67. Release 7.3.13

**Release date:** 2006-01-09

This release contains a variety of fixes from 7.3.12.

### E.67.1. Migration to Version 7.3.13

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.10, see the release notes for 7.3.10. Also, you might need to `REINDEX` indexes on textual columns after updating, if you are affected by the locale or `plperl` issues described below.

## E.67.2. Changes

- Fix character string comparison for locales that consider different character combinations as equal, such as Hungarian (Tom)

This might require `REINDEX` to fix existing indexes on textual columns.

- Set locale environment variables during postmaster startup to ensure that `plperl` won't change the locale later

This fixes a problem that occurred if the postmaster was started with environment variables specifying a different locale than what `initdb` had been told. Under these conditions, any use of `plperl` was likely to lead to corrupt indexes. You might need `REINDEX` to fix existing indexes on textual columns if this has happened to you.

- Fix longstanding bug in `strpos()` and regular expression handling in certain rarely used Asian multi-byte character sets (Tatsuo)
- Fix bug in `/contrib/pgcrypto` `gen_salt`, which caused it not to use all available salt space for MD5 and XDES algorithms (Marko Kreen, Solar Designer)

Salts for Blowfish and standard DES are unaffected.

- Fix `/contrib/dblink` to throw an error, rather than crashing, when the number of columns specified is different from what's actually returned by the query (Joe)

## E.68. Release 7.3.12

**Release date:** 2005-12-12

This release contains a variety of fixes from 7.3.11.

### E.68.1. Migration to Version 7.3.12

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.10, see the release notes for 7.3.10.

### E.68.2. Changes

- Fix race condition in transaction log management

There was a narrow window in which an I/O operation could be initiated for the wrong page, leading to an Assert failure or data corruption.

- `/contrib/ltree` fixes (Teodor)

- Fix longstanding planning error for outer joins

This bug sometimes caused a bogus error “RIGHT JOIN is only supported with merge-joinable join conditions”.

- Prevent core dump in `pg_autovacuum` when a table has been dropped

## E.69. Release 7.3.11

**Release date:** 2005-10-04

This release contains a variety of fixes from 7.3.10.

### E.69.1. Migration to Version 7.3.11

A dump/restore is not required for those running 7.3.X. However, if you are upgrading from a version earlier than 7.3.10, see the release notes for 7.3.10.

### E.69.2. Changes

- Fix error that allowed `VACUUM` to remove `ctid` chains too soon, and add more checking in code that follows `ctid` links

This fixes a long-standing problem that could cause crashes in very rare circumstances.

- Fix `CHAR()` to properly pad spaces to the specified length when using a multiple-byte character set (Yoshiyuki Asaba)

In prior releases, the padding of `CHAR()` was incorrect because it only padded to the specified number of bytes without considering how many characters were stored.

- Fix missing rows in queries like `UPDATE a=... WHERE a...` with GiST index on column `a`
- Improve checking for partially-written WAL pages
- Improve robustness of signal handling when SSL is enabled
- Various memory leakage fixes
- Various portability improvements
- Fix PL/PgSQL to handle `var := var` correctly when the variable is of pass-by-reference type

## E.70. Release 7.3.10

**Release date:** 2005-05-09

This release contains a variety of fixes from 7.3.9, including several security-related issues.

### E.70.1. Migration to Version 7.3.10

A dump/restore is not required for those running 7.3.X. However, it is one possible way of handling a significant security problem that has been found in the initial contents of 7.3.X system catalogs. A dump/initdb/reload sequence using 7.3.10's initdb will automatically correct this problem.

The security problem is that the built-in character set encoding conversion functions can be invoked from SQL commands by unprivileged users, but the functions were not designed for such use and are not secure against malicious choices of arguments. The fix involves changing the declared parameter list of these functions so that they can no longer be invoked from SQL commands. (This does not affect their normal use by the encoding conversion machinery.) It is strongly recommended that all installations repair this error, either by initdb or by following the manual repair procedure given below. The error at least allows unprivileged database users to crash their server process, and might allow unprivileged users to gain the privileges of a database superuser.

If you wish not to do an initdb, perform the following procedure instead. As the database superuser, do:

```
BEGIN;
UPDATE pg_proc SET proargtypes[3] = 'internal'::regtype
WHERE pronamespace = 11 AND pronargs = 5
    AND proargtypes[2] = 'cstring'::regtype;
-- The command should report having updated 90 rows;
-- if not, rollback and investigate instead of committing!
COMMIT;
```

The above procedure must be carried out in *each* database of an installation, including `template1`, and ideally including `template0` as well. If you do not fix the template databases then any subsequently created databases will contain the same error. `template1` can be fixed in the same way as any other database, but fixing `template0` requires additional steps. First, from any database issue:

```
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
```

Next connect to `template0` and perform the above repair procedure. Finally, do:

```
-- re-freeze template0:
VACUUM FREEZE;
-- and protect it against future alterations:
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';
```

## E.70.2. Changes

- Change encoding function signature to prevent misuse
- Repair ancient race condition that allowed a transaction to be seen as committed for some purposes (eg `SELECT FOR UPDATE`) slightly sooner than for other purposes

This is an extremely serious bug since it could lead to apparent data inconsistencies being briefly visible to applications.

- Repair race condition between relation extension and `VACUUM`

This could theoretically have caused loss of a page's worth of freshly-inserted data, although the scenario seems of very low probability. There are no known cases of it having caused more than an Assert failure.

- Fix comparisons of `TIME WITH TIME ZONE` values

The comparison code was wrong in the case where the `--enable-integer-datetimes` configuration switch had been used. NOTE: if you have an index on a `TIME WITH TIME ZONE` column, it will need to be `REINDEXED` after installing this update, because the fix corrects the sort order of column values.

- Fix `EXTRACT(EPOCH)` for `TIME WITH TIME ZONE` values
- Fix mis-display of negative fractional seconds in `INTERVAL` values

This error only occurred when the `--enable-integer-datetimes` configuration switch had been used.

- Additional buffer overrun checks in `plpgsql` (Neil)
- Fix `pg_dump` to dump trigger names containing `%` correctly (Neil)
- Prevent `to_char(interval)` from dumping core for month-related formats
- Fix `contrib/pgcrypto` for newer OpenSSL builds (Marko Kreen)
- Still more 64-bit fixes for `contrib/intagg`
- Prevent incorrect optimization of functions returning `RECORD`

## E.71. Release 7.3.9

**Release date:** 2005-01-31

This release contains a variety of fixes from 7.3.8, including several security-related issues.

### E.71.1. Migration to Version 7.3.9

A dump/restore is not required for those running 7.3.X.

## E.71.2. Changes

- Disallow `LOAD` to non-superusers

On platforms that will automatically execute initialization functions of a shared library (this includes at least Windows and ELF-based Unixen), `LOAD` can be used to make the server execute arbitrary code. Thanks to NGS Software for reporting this.

- Check that creator of an aggregate function has the right to execute the specified transition functions

This oversight made it possible to bypass denial of `EXECUTE` permission on a function.

- Fix security and 64-bit issues in contrib/intagg
- Add needed `STRICT` marking to some contrib functions (Kris Jurka)
- Avoid buffer overrun when `plpgsql` cursor declaration has too many parameters (Neil)
- Fix planning error for `FULL` and `RIGHT` outer joins

The result of the join was mistakenly supposed to be sorted the same as the left input. This could not only deliver mis-sorted output to the user, but in case of nested merge joins could give outright wrong answers.

- Fix `plperl` for quote marks in tuple fields
- Fix display of negative intervals in SQL and `GERMAN` datestyles

## E.72. Release 7.3.8

**Release date:** 2004-10-22

This release contains a variety of fixes from 7.3.7.

### E.72.1. Migration to Version 7.3.8

A dump/restore is not required for those running 7.3.X.

## E.72.2. Changes

- Repair possible failure to update hint bits on disk

Under rare circumstances this oversight could lead to “could not access transaction status” failures, which qualifies it as a potential-data-loss bug.

- Ensure that hashed outer join does not miss tuples

Very large left joins using a hash join plan could fail to output unmatched left-side rows given just the right data distribution.

- Disallow running `pg_ctl` as root

This is to guard against any possible security issues.

- Avoid using temp files in `/tmp` in `make_oidjoins_check`

This has been reported as a security issue, though it's hardly worthy of concern since there is no reason for non-developers to use this script anyway.

## E.73. Release 7.3.7

**Release date:** 2004-08-16

This release contains one critical fix over 7.3.6, and some minor items.

### E.73.1. Migration to Version 7.3.7

A dump/restore is not required for those running 7.3.X.

### E.73.2. Changes

- Prevent possible loss of committed transactions during crash

Due to insufficient interlocking between transaction commit and checkpointing, it was possible for transactions committed just before the most recent checkpoint to be lost, in whole or in part, following a database crash and restart. This is a serious bug that has existed since PostgreSQL 7.1.

- Remove asymmetrical word processing in `tsearch` (Teodor)
- Properly schema-qualify function names when `pg_dump`'ing a CAST

## E.74. Release 7.3.6

**Release date:** 2004-03-02

This release contains a variety of fixes from 7.3.5.

## E.74.1. Migration to Version 7.3.6

A dump/restore is *not* required for those running 7.3.\*.

## E.74.2. Changes

- Revert erroneous changes in rule permissions checking

A patch applied in 7.3.3 to fix a corner case in rule permissions checks turns out to have disabled rule-related permissions checks in many not-so-corner cases. This would for example allow users to insert into views they weren't supposed to have permission to insert into. We have therefore reverted the 7.3.3 patch. The original bug will be fixed in 8.0.

- Repair incorrect order of operations in GetNewTransactionId()

This bug could result in failure under out-of-disk-space conditions, including inability to restart even after disk space is freed.

- Ensure configure selects -fno-strict-aliasing even when an external value for CFLAGS is supplied

On some platforms, building with -fstrict-aliasing causes bugs.

- Make pg\_restore handle 64-bit off\_t correctly

This bug prevented proper restoration from archive files exceeding 4 GB.

- Make contrib/dblink not assume that local and remote type OIDs match (Joe)

- Quote connectby()'s start\_with argument properly (Joe)

- Don't crash when a rowtype argument to a plpgsql function is NULL

- Avoid generating invalid character encoding sequences in corner cases when planning LIKE operations

- Ensure text\_position() cannot scan past end of source string in multibyte cases (Korea PostgreSQL Users' Group)

- Fix index optimization and selectivity estimates for LIKE operations on bytea columns (Joe)

## E.75. Release 7.3.5

**Release date:** 2003-12-03

This has a variety of fixes from 7.3.4.

## E.75.1. Migration to Version 7.3.5

A dump/restore is *not* required for those running 7.3.\*.

## E.75.2. Changes

- Force zero\_damaged\_pages to be on during recovery from WAL
- Prevent some obscure cases of “variable not in subplan target lists”
- Force stats processes to detach from shared memory, ensuring cleaner shutdown
- Make PQescapeBytea and byteaout consistent with each other (Joe)
- Added missing SPI\_finish() calls to dblink’s get\_tuple\_of\_interest() (Joe)
- Fix for possible foreign key violation when rule rewrites INSERT (Jan)
- Support qualified type names in PL/Tcl’s spi\_prepare command (Jan)
- Make pg\_dump handle a procedural language handler located in pg\_catalog
- Make pg\_dump handle cases where a custom opclass is in another schema
- Make pg\_dump dump binary-compatible casts correctly (Jan)
- Fix insertion of expressions containing subqueries into rule bodies
- Fix incorrect argument processing in clusterdb script (Anand Ranganathan)
- Fix problems with dropped columns in plpython triggers
- Repair problems with to\_char() reading past end of its input string (Karel)
- Fix GB18030 mapping errors (Tatsuo)
- Fix several problems with SSL error handling and asynchronous SSL I/O
- Remove ability to bind a list of values to a single parameter in JDBC (prevents possible SQL-injection attacks)
- Fix some errors in HAVE\_INT64\_TIMESTAMP code paths
- Fix corner case for btree search in parallel with first root page split

## E.76. Release 7.3.4

**Release date:** 2003-07-24

This has a variety of fixes from 7.3.3.

### E.76.1. Migration to Version 7.3.4

A dump/restore is *not* required for those running 7.3.\*.

## E.76.2. Changes

- Repair breakage in timestamp-to-date conversion for dates before 2000
- Prevent rare possibility of server startup failure (Tom)
- Fix bugs in interval-to-time conversion (Tom)
- Add constraint names in a few places in `pg_dump` (Rod)
- Improve performance of functions with many parameters (Tom)
- Fix `to_ascii()` buffer overruns (Tom)
- Prevent restore of database comments from throwing an error (Tom)
- Work around buggy `strxfrm()` present in some Solaris releases (Tom)
- Properly escape jdbc `setObject()` strings to improve security (Barry)

## E.77. Release 7.3.3

**Release date:** 2003-05-22

This release contains a variety of fixes for version 7.3.2.

### E.77.1. Migration to Version 7.3.3

A dump/restore is *not* required for those running version 7.3.\*.

### E.77.2. Changes

- Repair sometimes-incorrect computation of `StartUpID` after a crash
- Avoid slowness with lots of deferred triggers in one transaction (Stephan)
- Don't lock referenced row when `UPDATE` doesn't change foreign key's value (Jan)
- Use `-fPIC` not `-fpic` on Sparc (Tom Callaway)
- Repair lack of schema-awareness in contrib/reindexdb
- Fix contrib/intarray error for zero-element result array (Teodor)
- Ensure `createuser` script will exit on control-C (Oliver)
- Fix errors when the type of a dropped column has itself been dropped
- `CHECKPOINT` does not cause database panic on failure in noncritical steps
- Accept 60 in seconds fields of timestamp, time, interval input values

- Issue notice, not error, if `TIMESTAMP`, `TIME`, or `INTERVAL` precision too large
- Fix `abstime-to-time` cast function (fix is not applied unless you `initdb`)
- Fix `pg_proc` entry for `timestamp_tz_izone` (fix is not applied unless you `initdb`)
- Make `EXTRACT(EPOCH FROM timestamp without time zone)` treat input as local time
- `'now'::timestamp_tz` gave wrong answer if timezone changed earlier in transaction
- `HAVE_INT64_TIMESTAMP` code for time with timezone overwrote its input
- Accept `GLOBAL TEMP/TEMPORARY` as a synonym for `TEMPORARY`
- Avoid improper schema-privilege-check failure in foreign-key triggers
- Fix bugs in foreign-key triggers for `SET DEFAULT` action
- Fix incorrect time-qual check in row fetch for `UPDATE` and `DELETE` triggers
- Foreign-key clauses were parsed but ignored in `ALTER TABLE ADD COLUMN`
- Fix `createlang` script breakage for case where handler function already exists
- Fix misbehavior on zero-column tables in `pg_dump`, `COPY`, `ANALYZE`, other places
- Fix misbehavior of `func_error()` on type names containing `'%'`
- Fix misbehavior of `replace()` on strings containing `'%'`
- Regular-expression patterns containing certain multibyte characters failed
- Account correctly for `NULLs` in more cases in join size estimation
- Avoid conflict with system definition of `isblank()` function or macro
- Fix failure to convert large code point values in `EUC_TW` conversions (Tatsuo)
- Fix error recovery for `SSL_read/SSL_write` calls
- Don't do early constant-folding of type coercion expressions
- Validate page header fields immediately after reading in any page
- Repair incorrect check for ungrouped variables in unnamed joins
- Fix buffer overrun in `to_ascii` (Guido Notari)
- `contrib/ltree` fixes (Teodor)
- Fix core dump in deadlock detection on machines where `char` is unsigned
- Avoid running out of buffers in many-way `indexscan` (bug introduced in 7.3)
- Fix planner's selectivity estimation functions to handle domains properly
- Fix `dbmirror` memory-allocation bug (Steven Singer)
- Prevent infinite loop in `ln(numeric)` due to roundoff error
- `GROUP BY` got confused if there were multiple equal `GROUP BY` items
- Fix bad plan when inherited `UPDATE/DELETE` references another inherited table
- Prevent clustering on incomplete (partial or non-`NULL`-storing) indexes
- Service shutdown request at proper time if it arrives while still starting up
- Fix left-links in temporary indexes (could make backwards scans miss entries)

- Fix incorrect handling of `client_encoding` setting in `postgresql.conf` (Tatsuo)
- Fix failure to respond to `pg_ctl stop -m fast` after `Async_NotifyHandler` runs
- Fix SPI for case where rule contains multiple statements of the same type
- Fix problem with checking for wrong type of access privilege in rule query
- Fix problem with `EXCEPT` in `CREATE RULE`
- Prevent problem with dropping temp tables having serial columns
- Fix `replace_vars_with_subplan_refs` failure in complex views
- Fix regexp slowness in single-byte encodings (Tatsuo)
- Allow qualified type names in `CREATE CAST` and `DROP CAST`
- Accept `SETOF type[]`, which formerly had to be written `SETOF _type`
- Fix `pg_dump` core dump in some cases with procedural languages
- Force ISO datestyle in `pg_dump` output, for portability (Oliver)
- `pg_dump` failed to handle error return from `lo_read` (Oleg Drokin)
- `pg_dumpall` failed with groups having no members (Nick Eskelinen)
- `pg_dumpall` failed to recognize `--globals-only` switch
- `pg_restore` failed to restore blobs if `-X disable-triggers` is specified
- Repair intrafunction memory leak in `plpgsql`
- `pltcl`'s `elog` command dumped core if given wrong parameters (Ian Harding)
- `pypython` used wrong value of `atttypmod` (Brad McLean)
- Fix improper quoting of boolean values in Python interface (D'Arcy)
- Added `addDataType()` method to `PGConnection` interface for JDBC
- Fixed various problems with updateable `ResultSets` for JDBC (Shawn Green)
- Fixed various problems with `DatabaseMetaData` for JDBC (Kris Jurka, Peter Royal)
- Fixed problem with parsing table ACLs in JDBC
- Better error message for character set conversion problems in JDBC

## E.78. Release 7.3.2

**Release date:** 2003-02-04

This release contains a variety of fixes for version 7.3.1.

## E.78.1. Migration to Version 7.3.2

A dump/restore is *not* required for those running version 7.3.\*.

## E.78.2. Changes

- Restore creation of OID column in CREATE TABLE AS / SELECT INTO
- Fix pg\_dump core dump when dumping views having comments
- Dump DEFERRABLE/INITIALLY DEFERRED constraints properly
- Fix UPDATE when child table's column numbering differs from parent
- Increase default value of max\_fsm\_relations
- Fix problem when fetching backwards in a cursor for a single-row query
- Make backward fetch work properly with cursor on SELECT DISTINCT query
- Fix problems with loading pg\_dump files containing contrib/lo usage
- Fix problem with all-numeric user names
- Fix possible memory leak and core dump during disconnect in libpgtcl
- Make plpython's spi\_execute command handle nulls properly (Andrew Bosma)
- Adjust plpython error reporting so that its regression test passes again
- Work with bison 1.875
- Handle mixed-case names properly in plpgsql's %type (Neil)
- Fix core dump in pltcl when executing a query rewritten by a rule
- Repair array subscript overruns (per report from Yichen Xie)
- Reduce MAX\_TIME\_PRECISION from 13 to 10 in floating-point case
- Correctly case-fold variable names in per-database and per-user settings
- Fix coredump in plpgsql's RETURN NEXT when SELECT into record returns no rows
- Fix outdated use of pg\_type.typprtlen in python client interface
- Correctly handle fractional seconds in timestamps in JDBC driver
- Improve performance of getImportedKeys() in JDBC
- Make shared-library symlinks work standardly on HP/UX (Giles)
- Repair inconsistent rounding behavior for timestamp, time, interval
- SSL negotiation fixes (Nathan Mueller)
- Make libpq's ~/.pgpass feature work when connecting with PQconnectDB
- Update my2pg, ora2pg
- Translation updates
- Add casts between types lo and oid in contrib/lo

- fastpath code now checks for privilege to call function

## E.79. Release 7.3.1

**Release date:** 2002-12-18

This release contains a variety of fixes for version 7.3.

### E.79.1. Migration to Version 7.3.1

A dump/restore is *not* required for those running version 7.3. However, it should be noted that the main PostgreSQL interface library, libpq, has a new major version number for this release, which might require recompilation of client code in certain cases.

### E.79.2. Changes

- Fix a core dump of COPY TO when client/server encodings don't match (Tom)
- Allow pg\_dump to work with pre-7.2 servers (Philip)
- contrib/adddepend fixes (Tom)
- Fix problem with deletion of per-user/per-database config settings (Tom)
- contrib/vacuumlo fix (Tom)
- Allow 'password' encryption even when pg\_shadow contains MD5 passwords (Bruce)
- contrib/dbmirror fix (Steven Singer)
- Optimizer fixes (Tom)
- contrib/tsearch fixes (Teodor Sigaev, Magnus)
- Allow locale names to be mixed case (Nicolai Tufar)
- Increment libpq library's major version number (Bruce)
- pg\_hba.conf error reporting fixes (Bruce, Neil)
- Add SCO Openserver 5.0.4 as a supported platform (Bruce)
- Prevent EXPLAIN from crashing server (Tom)
- SSL fixes (Nathan Mueller)
- Prevent composite column creation via ALTER TABLE (Tom)

## E.80. Release 7.3

**Release date:** 2002-11-27

### E.80.1. Overview

Major changes in this release:

#### Schemas

Schemas allow users to create objects in separate namespaces, so two people or applications can have tables with the same name. There is also a public schema for shared tables. Table/index creation can be restricted by removing privileges on the public schema.

#### Drop Column

PostgreSQL now supports the `ALTER TABLE ... DROP COLUMN` functionality.

#### Table Functions

Functions returning multiple rows and/or multiple columns are now much easier to use than before. You can call such a “table function” in the `SELECT FROM` clause, treating its output like a table. Also, PL/pgSQL functions can now return sets.

#### Prepared Queries

PostgreSQL now supports prepared queries, for improved performance.

#### Dependency Tracking

PostgreSQL now records object dependencies, which allows improvements in many areas. `DROP` statements now take either `CASCADE` or `RESTRICT` to control whether dependent objects are also dropped.

#### Privileges

Functions and procedural languages now have privileges, and functions can be defined to run with the privileges of their creator.

#### Internationalization

Both multibyte and locale support are now always enabled.

#### Logging

A variety of logging options have been enhanced.

#### Interfaces

A large number of interfaces have been moved to <http://gborg.postgresql.org> where they can be developed and released independently.

#### Functions/Identifiers

By default, functions can now take up to 32 parameters, and identifiers can be up to 63 bytes long. Also, `OPAQUE` is now deprecated: there are specific “pseudo-datatypes” to represent each of the former meanings of `OPAQUE` in function argument and result types.

## E.80.2. Migration to Version 7.3

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release. If your application examines the system catalogs, additional changes will be required due to the introduction of schemas in 7.3; for more information, see: [http://developer.postgresql.org/~momjian/upgrade\\_tips\\_7.3](http://developer.postgresql.org/~momjian/upgrade_tips_7.3).

Observe the following incompatibilities:

- Pre-6.3 clients are no longer supported.
- `pg_hba.conf` now has a column for the user name and additional features. Existing files need to be adjusted.
- Several `postgresql.conf` logging parameters have been renamed.
- `LIMIT #, #` has been disabled; use `LIMIT # OFFSET #`.
- `INSERT` statements with column lists must specify a value for each specified column. For example, `INSERT INTO tab (col1, col2) VALUES ('vall')` is now invalid. It's still allowed to supply fewer columns than expected if the `INSERT` does not have a column list.
- `serial` columns are no longer automatically `UNIQUE`; thus, an index will not automatically be created.
- A `SET` command inside an aborted transaction is now rolled back.
- `COPY` no longer considers missing trailing columns to be null. All columns need to be specified. (However, one can achieve a similar effect by specifying a column list in the `COPY` command.)
- The data type `timestamp` is now equivalent to `timestamp without time zone`, instead of `timestamp with time zone`.
- Pre-7.3 databases loaded into 7.3 will not have the new object dependencies for `serial` columns, unique constraints, and foreign keys. See the directory `contrib/adddepend/` for a detailed description and a script that will add such dependencies.
- An empty string (") is no longer allowed as the input into an integer field. Formerly, it was silently interpreted as 0.

## E.80.3. Changes

### E.80.3.1. Server Operation

- Add `pg_locks` view to show locks (Neil)
- Security fixes for password negotiation memory allocation (Neil)
- Remove support for version 0 FE/BE protocol (PostgreSQL 6.2 and earlier) (Tom)
- Reserve the last few backend slots for superusers, add parameter `superuser_reserved_connections` to control this (Nigel J. Andrews)

### **E.80.3.2. Performance**

- Improve startup by calling localtime() only once (Tom)
- Cache system catalog information in flat files for faster startup (Tom)
- Improve caching of index information (Tom)
- Optimizer improvements (Tom, Fernando Nasser)
- Catalog caches now store failed lookups (Tom)
- Hash function improvements (Neil)
- Improve performance of query tokenization and network handling (Peter)
- Speed improvement for large object restore (Mario Weilguni)
- Mark expired index entries on first lookup, saving later heap fetches (Tom)
- Avoid excessive NULL bitmap padding (Manfred Koizar)
- Add BSD-licensed qsort() for Solaris, for performance (Bruce)
- Reduce per-row overhead by four bytes (Manfred Koizar)
- Fix GEQO optimizer bug (Neil Conway)
- Make WITHOUT OID actually save four bytes per row (Manfred Koizar)
- Add default\_statistics\_target variable to specify ANALYZE buckets (Neil)
- Use local buffer cache for temporary tables so no WAL overhead (Tom)
- Improve free space map performance on large tables (Stephen Marshall, Tom)
- Improved WAL write concurrency (Tom)

### **E.80.3.3. Privileges**

- Add privileges on functions and procedural languages (Peter)
- Add OWNER to CREATE DATABASE so superusers can create databases on behalf of unprivileged users (Gavin Sherry, Tom)
- Add new object privilege bits EXECUTE and USAGE (Tom)
- Add SET SESSION AUTHORIZATION DEFAULT and RESET SESSION AUTHORIZATION (Tom)
- Allow functions to be executed with the privilege of the function owner (Peter)

### **E.80.3.4. Server Configuration**

- Server log messages now tagged with LOG, not DEBUG (Bruce)
- Add user column to pg\_hba.conf (Bruce)
- Have log\_connections output two lines in log file (Tom)

- Remove `debug_level` from `postgresql.conf`, now `server_min_messages` (Bruce)
- New `ALTER DATABASE/USER ... SET` command for per-user/database initialization (Peter)
- New parameters `server_min_messages` and `client_min_messages` to control which messages are sent to the server logs or client applications (Bruce)
- Allow `pg_hba.conf` to specify lists of users/databases separated by commas, group names prepended with `+`, and file names prepended with `@` (Bruce)
- Remove secondary password file capability and `pg_password` utility (Bruce)
- Add variable `db_user_namespace` for database-local user names (Bruce)
- SSL improvements (Bear Giles)
- Make encryption of stored passwords the default (Bruce)
- Allow `pg_statistics` to be reset by calling `pg_stat_reset()` (Christopher)
- Add `log_duration` parameter (Bruce)
- Rename `debug_print_query` to `log_statement` (Bruce)
- Rename `show_query_stats` to `show_statement_stats` (Bruce)
- Add param `log_min_error_statement` to print commands to logs on error (Gavin)

### E.80.3.5. Queries

- Make cursors insensitive, meaning their contents do not change (Tom)
- Disable `LIMIT #, #` syntax; now only `LIMIT # OFFSET #` supported (Bruce)
- Increase identifier length to 63 (Neil, Bruce)
- `UNION` fixes for merging  $\geq 3$  columns of different lengths (Tom)
- Add `DEFAULT` key word to `INSERT`, e.g., `INSERT ... (... , DEFAULT, ...)` (Rod)
- Allow views to have default values using `ALTER COLUMN ... SET DEFAULT` (Neil)
- Fail on `INSERTs` with column lists that don't supply all column values, e.g., `INSERT INTO tab (col1, col2) VALUES ('val1')`; (Rod)
- Fix for join aliases (Tom)
- Fix for `FULL OUTER JOINS` (Tom)
- Improve reporting of invalid identifier and location (Tom, Gavin)
- Fix `OPEN cursor(args)` (Tom)
- Allow `'ctid'` to be used in a view and `currtd(viewname)` (Hiroshi)
- Fix for `CREATE TABLE AS` with `UNION` (Tom)
- SQL99 syntax improvements (Thomas)
- Add `statement_timeout` variable to cancel queries (Bruce)
- Allow prepared queries with `PREPARE/EXECUTE` (Neil)

- Allow FOR UPDATE to appear after LIMIT/OFFSET (Bruce)
- Add variable autocommit (Tom, David Van Wie)

### **E.80.3.6. Object Manipulation**

- Make equals signs optional in CREATE DATABASE (Gavin Sherry)
- Make ALTER TABLE OWNER change index ownership too (Neil)
- New ALTER TABLE tablename ALTER COLUMN colname SET STORAGE controls TOAST storage, compression (John Gray)
- Add schema support, CREATE/DROP SCHEMA (Tom)
- Create schema for temporary tables (Tom)
- Add variable search\_path for schema search (Tom)
- Add ALTER TABLE SET/DROP NOT NULL (Christopher)
- New CREATE FUNCTION volatility levels (Tom)
- Make rule names unique only per table (Tom)
- Add 'ON tablename' clause to DROP RULE and COMMENT ON RULE (Tom)
- Add ALTER TRIGGER RENAME (Joe)
- New current\_schema() and current\_schemas() inquiry functions (Tom)
- Allow functions to return multiple rows (table functions) (Joe)
- Make WITH optional in CREATE DATABASE, for consistency (Bruce)
- Add object dependency tracking (Rod, Tom)
- Add RESTRICT/CASCADE to DROP commands (Rod)
- Add ALTER TABLE DROP for non-CHECK CONSTRAINT (Rod)
- Autodestroy sequence on DROP of table with SERIAL (Rod)
- Prevent column dropping if column is used by foreign key (Rod)
- Automatically drop constraints/functions when object is dropped (Rod)
- Add CREATE/DROP OPERATOR CLASS (Bill Studenmund, Tom)
- Add ALTER TABLE DROP COLUMN (Christopher, Tom, Hiroshi)
- Prevent inherited columns from being removed or renamed (Alvaro Herrera)
- Fix foreign key constraints to not error on intermediate database states (Stephan)
- Propagate column or table renaming to foreign key constraints
- Add CREATE OR REPLACE VIEW (Gavin, Neil, Tom)
- Add CREATE OR REPLACE RULE (Gavin, Neil, Tom)
- Have rules execute alphabetically, returning more predictable values (Tom)
- Triggers are now fired in alphabetical order (Tom)

- Add /contrib/adddepend to handle pre-7.3 object dependencies (Rod)
- Allow better casting when inserting/updating values (Tom)

### **E.80.3.7. Utility Commands**

- Have COPY TO output embedded carriage returns and newlines as \r and \n (Tom)
- Allow DELIMITER in COPY FROM to be 8-bit clean (Tatsuo)
- Make pg\_dump use ALTER TABLE ADD PRIMARY KEY, for performance (Neil)
- Disable brackets in multistatement rules (Bruce)
- Disable VACUUM from being called inside a function (Bruce)
- Allow dropdb and other scripts to use identifiers with spaces (Bruce)
- Restrict database comment changes to the current database
- Allow comments on operators, independent of the underlying function (Rod)
- Rollback SET commands in aborted transactions (Tom)
- EXPLAIN now outputs as a query (Tom)
- Display condition expressions and sort keys in EXPLAIN (Tom)
- Add 'SET LOCAL var = value' to set configuration variables for a single transaction (Tom)
- Allow ANALYZE to run in a transaction (Bruce)
- Improve COPY syntax using new WITH clauses, keep backward compatibility (Bruce)
- Fix pg\_dump to consistently output tags in non-ASCII dumps (Bruce)
- Make foreign key constraints clearer in dump file (Rod)
- Add COMMENT ON CONSTRAINT (Rod)
- Allow COPY TO/FROM to specify column names (Brent Verner)
- Dump UNIQUE and PRIMARY KEY constraints as ALTER TABLE (Rod)
- Have SHOW output a query result (Joe)
- Generate failure on short COPY lines rather than pad NULLs (Neil)
- Fix CLUSTER to preserve all table attributes (Alvaro Herrera)
- New pg\_settings table to view/modify GUC settings (Joe)
- Add smart quoting, portability improvements to pg\_dump output (Peter)
- Dump serial columns out as SERIAL (Tom)
- Enable large file support, >2G for pg\_dump (Peter, Philip Warner, Bruce)
- Disallow TRUNCATE on tables that are involved in referential constraints (Rod)
- Have TRUNCATE also auto-truncate the toast table of the relation (Tom)
- Add clusterdb utility that will auto-cluster an entire database based on previous CLUSTER operations (Alvaro Herrera)

- Overhaul pg\_dumpall (Peter)
- Allow REINDEX of TOAST tables (Tom)
- Implemented START TRANSACTION, per SQL99 (Neil)
- Fix rare index corruption when a page split affects bulk delete (Tom)
- Fix ALTER TABLE ... ADD COLUMN for inheritance (Alvaro Herrera)

### **E.80.3.8. Data Types and Functions**

- Fix factorial(0) to return 1 (Bruce)
- Date/time/timezone improvements (Thomas)
- Fix for array slice extraction (Tom)
- Fix extract/date\_part to report proper microseconds for timestamp (Tatsuo)
- Allow text\_substr() and bytea\_substr() to read TOAST values more efficiently (John Gray)
- Add domain support (Rod)
- Make WITHOUT TIME ZONE the default for TIMESTAMP and TIME data types (Thomas)
- Allow alternate storage scheme of 64-bit integers for date/time types using --enable-integer-datetimes in configure (Thomas)
- Make timezone(timestamptz) return timestamp rather than a string (Thomas)
- Allow fractional seconds in date/time types for dates prior to 1BC (Thomas)
- Limit timestamp data types to 6 decimal places of precision (Thomas)
- Change timezone conversion functions from timetz() to timezone() (Thomas)
- Add configuration variables datestyle and timezone (Tom)
- Add OVERLAY(), which allows substitution of a substring in a string (Thomas)
- Add SIMILAR TO (Thomas, Tom)
- Add regular expression SUBSTRING(string FROM pat FOR escape) (Thomas)
- Add LOCALTIME and LOCALTIMESTAMP functions (Thomas)
- Add named composite types using CREATE TYPE typename AS (column) (Joe)
- Allow composite type definition in the table alias clause (Joe)
- Add new API to simplify creation of C language table functions (Joe)
- Remove ODBC-compatible empty parentheses from calls to SQL99 functions for which these parentheses do not match the standard (Thomas)
- Allow macaddr data type to accept 12 hex digits with no separators (Mike Wyer)
- Add CREATE/DROP CAST (Peter)
- Add IS DISTINCT FROM operator (Thomas)
- Add SQL99 TREAT() function, synonym for CAST() (Thomas)

- Add `pg_backend_pid()` to output backend pid (Bruce)
- Add IS OF / IS NOT OF type predicate (Thomas)
- Allow bit string constants without fully-specified length (Thomas)
- Allow conversion between 8-byte integers and bit strings (Thomas)
- Implement hex literal conversion to bit string literal (Thomas)
- Allow table functions to appear in the FROM clause (Joe)
- Increase maximum number of function parameters to 32 (Bruce)
- No longer automatically create index for SERIAL column (Tom)
- Add `current_database()` (Rod)
- Fix `cash_words()` to not overflow buffer (Tom)
- Add functions `replace()`, `split_part()`, `to_hex()` (Joe)
- Fix LIKE for bytea as a right-hand argument (Joe)
- Prevent crashes caused by `SELECT cash_out(2)` (Tom)
- Fix `to_char(1,'FM999.99')` to return a period (Karel)
- Fix trigger/type/language functions returning OPAQUE to return proper type (Tom)

### **E.80.3.9. Internationalization**

- Add additional encodings: Korean (JOHAB), Thai (WIN874), Vietnamese (TCVN), Arabic (WIN1256), Simplified Chinese (GBK), Korean (UHC) (Eiji Tokuya)
- Enable locale support by default (Peter)
- Add locale variables (Peter)
- Escape bytes `>= 0x7f` for multibyte in `PQescapeBytea/PQunescapeBytea` (Tatsuo)
- Add locale awareness to regular expression character classes
- Enable multibyte support by default (Tatsuo)
- Add GB18030 multibyte support (Bill Huang)
- Add CREATE/DROP CONVERSION, allowing loadable encodings (Tatsuo, Kaori)
- Add `pg_conversion` table (Tatsuo)
- Add SQL99 `CONVERT()` function (Tatsuo)
- `pg_dumpall`, `pg_controldata`, and `pg_resetxlog` now national-language aware (Peter)
- New and updated translations

### **E.80.3.10. Server-side Languages**

- Allow recursive SQL function (Peter)

- Change PL/Tcl build to use configured compiler and Makefile.shlib (Peter)
- Overhaul the PL/pgSQL FOUND variable to be more Oracle-compatible (Neil, Tom)
- Allow PL/pgSQL to handle quoted identifiers (Tom)
- Allow set-returning PL/pgSQL functions (Neil)
- Make PL/pgSQL schema-aware (Joe)
- Remove some memory leaks (Nigel J. Andrews, Tom)

### **E.80.3.11. psql**

- Don't lowercase psql \connect database name for 7.2.0 compatibility (Tom)
- Add psql \timing to time user queries (Greg Sabino Mullane)
- Have psql \d show index information (Greg Sabino Mullane)
- New psql \dD shows domains (Jonathan Eisler)
- Allow psql to show rules on views (Paul ?)
- Fix for psql variable substitution (Tom)
- Allow psql \d to show temporary table structure (Tom)
- Allow psql \d to show foreign keys (Rod)
- Fix \? to honor \set pager (Bruce)
- Have psql reports its version number on startup (Tom)
- Allow \copy to specify column names (Tom)

### **E.80.3.12. libpq**

- Add ~/.pgpass to store host/user password combinations (Alvaro Herrera)
- Add PQunescapeBytea() function to libpq (Patrick Welche)
- Fix for sending large queries over non-blocking connections (Bernhard Herzog)
- Fix for libpq using timers on Win9X (David Ford)
- Allow libpq notify to handle servers with different-length identifiers (Tom)
- Add libpq PQescapeString() and PQescapeBytea() to Windows (Bruce)
- Fix for SSL with non-blocking connections (Jack Bates)
- Add libpq connection timeout parameter (Denis A Ustimenko)

### **E.80.3.13. JDBC**

- Allow JDBC to compile with JDK 1.4 (Dave)
- Add JDBC 3 support (Barry)
- Allows JDBC to set loglevel by adding ?loglevel=X to the connection URL (Barry)
- Add Driver.info() message that prints out the version number (Barry)
- Add updateable result sets (Raghu Nidagal, Dave)
- Add support for callable statements (Paul Bethe)
- Add query cancel capability
- Add refresh row (Dave)
- Fix MD5 encryption handling for multibyte servers (Jun Kawai)
- Add support for prepared statements (Barry)

### **E.80.3.14. Miscellaneous Interfaces**

- Fixed ECPG bug concerning octal numbers in single quotes (Michael)
- Move src/interfaces/libpqeasy to <http://gborg.postgresql.org> (Marc, Bruce)
- Improve Python interface (Elliot Lee, Andrew Johnson, Greg Copeland)
- Add libpqctl connection close event (Gerhard Hintermayer)
- Move src/interfaces/libpq++ to <http://gborg.postgresql.org> (Marc, Bruce)
- Move src/interfaces/odbc to <http://gborg.postgresql.org> (Marc)
- Move src/interfaces/libpqeasy to <http://gborg.postgresql.org> (Marc, Bruce)
- Move src/interfaces/perl5 to <http://gborg.postgresql.org> (Marc, Bruce)
- Remove src/bin/pgaccess from main tree, now at <http://www.pgaccess.org> (Bruce)
- Add pg\_on\_connection\_loss command to libpqctl (Gerhard Hintermayer, Tom)

### **E.80.3.15. Source Code**

- Fix for parallel make (Peter)
- AIX fixes for linking Tcl (Andreas Zeugswetter)
- Allow PL/Perl to build under Cygwin (Jason Tishler)
- Improve MIPS compiles (Peter, Oliver Elphick)
- Require Autoconf version 2.53 (Peter)
- Require readline and zlib by default in configure (Peter)
- Allow Solaris to use Intimate Shared Memory (ISM), for performance (Scott Brunza, P.J. Josh Rovero)

- Always enable syslog in compile, remove --enable-syslog option (Tatsuo)
- Always enable multibyte in compile, remove --enable-multibyte option (Tatsuo)
- Always enable locale in compile, remove --enable-locale option (Peter)
- Fix for Win9x DLL creation (Magnus Naeslund)
- Fix for link() usage by WAL code on Windows, BeOS (Jason Tishler)
- Add sys/types.h to c.h, remove from main files (Peter, Bruce)
- Fix AIX hang on SMP machines (Tomoyuki Nijima)
- AIX SMP hang fix (Tomoyuki Nijima)
- Fix pre-1970 date handling on newer glibc libraries (Tom)
- Fix PowerPC SMP locking (Tom)
- Prevent gcc -ffast-math from being used (Peter, Tom)
- Bison >= 1.50 now required for developer builds
- Kerberos 5 support now builds with Heimdal (Peter)
- Add appendix in the User's Guide which lists SQL features (Thomas)
- Improve loadable module linking to use RTLD\_NOW (Tom)
- New error levels WARNING, INFO, LOG, DEBUG[1-5] (Bruce)
- New src/port directory holds replaced libc functions (Peter, Bruce)
- New pg\_namespace system catalog for schemas (Tom)
- Add pg\_class.relnamespace for schemas (Tom)
- Add pg\_type.typnamespace for schemas (Tom)
- Add pg\_proc.pronamespace for schemas (Tom)
- Restructure aggregates to have pg\_proc entries (Tom)
- System relations now have their own namespace, pg\_\* test not required (Fernando Nasser)
- Rename TOAST index names to be \*\_index rather than \*\_idx (Neil)
- Add namespaces for operators, opclasses (Tom)
- Add additional checks to server control file (Thomas)
- New Polish FAQ (Marcin Mazurek)
- Add Posix semaphore support (Tom)
- Document need for reindex (Bruce)
- Rename some internal identifiers to simplify Windows compile (Jan, Katherine Ward)
- Add documentation on computing disk space (Bruce)
- Remove KSQO from GUC (Bruce)
- Fix memory leak in rtree (Kenneth Been)
- Modify a few error messages for consistency (Bruce)
- Remove unused system table columns (Peter)

- Make system columns NOT NULL where appropriate (Tom)
- Clean up use of sprintf in favor of snprintf() (Neil, Jukka Holappa)
- Remove OPAQUE and create specific subtypes (Tom)
- Cleanups in array internal handling (Joe, Tom)
- Disallow pg\_atoi("") (Bruce)
- Remove parameter wal\_files because WAL files are now recycled (Bruce)
- Add version numbers to heap pages (Tom)

### **E.80.3.16. Contrib**

- Allow inet arrays in /contrib/array (Neil)
- GiST fixes (Teodor Sigaev, Neil)
- Upgrade /contrib/mysql
- Add /contrib/dbsize which shows table sizes without vacuum (Peter)
- Add /contrib/intagg, integer aggregator routines (mlw)
- Improve /contrib/oid2name (Neil, Bruce)
- Improve /contrib/tsearch (Oleg, Teodor Sigaev)
- Cleanups of /contrib/rserver (Alexey V. Borzov)
- Update /contrib/oracle conversion utility (Gilles Darold)
- Update /contrib/dblink (Joe)
- Improve options supported by /contrib/vacuumlo (Mario Weilguni)
- Improvements to /contrib/intarray (Oleg, Teodor Sigaev, Andrey Oktyabrski)
- Add /contrib/reindexdb utility (Shaun Thomas)
- Add indexing to /contrib/isbn\_issn (Dan Weston)
- Add /contrib/dbmirror (Steven Singer)
- Improve /contrib/pgbench (Neil)
- Add /contrib/tablefunc table function examples (Joe)
- Add /contrib/ltree data type for tree structures (Teodor Sigaev, Oleg Bartunov)
- Move /contrib/pg\_controldata, pg\_resetxlog into main tree (Bruce)
- Fixes to /contrib/cube (Bruno Wolff)
- Improve /contrib/fulltextindex (Christopher)

## E.81. Release 7.2.8

**Release date:** 2005-05-09

This release contains a variety of fixes from 7.2.7, including one security-related issue.

### E.81.1. Migration to Version 7.2.8

A dump/restore is not required for those running 7.2.X.

### E.81.2. Changes

- Repair ancient race condition that allowed a transaction to be seen as committed for some purposes (eg `SELECT FOR UPDATE`) slightly sooner than for other purposes

This is an extremely serious bug since it could lead to apparent data inconsistencies being briefly visible to applications.

- Repair race condition between relation extension and `VACUUM`

This could theoretically have caused loss of a page's worth of freshly-inserted data, although the scenario seems of very low probability. There are no known cases of it having caused more than an `Assert` failure.

- Fix `EXTRACT(EPOCH)` for `TIME WITH TIME ZONE` values
- Additional buffer overrun checks in `plpgsql` (Neil)
- Fix `pg_dump` to dump index names and trigger names containing `%` correctly (Neil)
- Prevent `to_char(interval)` from dumping core for month-related formats
- Fix `contrib/pgcrypto` for newer OpenSSL builds (Marko Kreen)

## E.82. Release 7.2.7

**Release date:** 2005-01-31

This release contains a variety of fixes from 7.2.6, including several security-related issues.

### E.82.1. Migration to Version 7.2.7

A dump/restore is not required for those running 7.2.X.

## E.82.2. Changes

- Disallow `LOAD` to non-superusers

On platforms that will automatically execute initialization functions of a shared library (this includes at least Windows and ELF-based Unixen), `LOAD` can be used to make the server execute arbitrary code. Thanks to NGS Software for reporting this.

- Add needed `STRICT` marking to some contrib functions (Kris Jurka)
- Avoid buffer overrun when `plpgsql` cursor declaration has too many parameters (Neil)
- Fix planning error for `FULL` and `RIGHT` outer joins

The result of the join was mistakenly supposed to be sorted the same as the left input. This could not only deliver mis-sorted output to the user, but in case of nested merge joins could give outright wrong answers.

- Fix display of negative intervals in `SQL` and `GERMAN` datestyles

## E.83. Release 7.2.6

**Release date:** 2004-10-22

This release contains a variety of fixes from 7.2.5.

### E.83.1. Migration to Version 7.2.6

A dump/restore is not required for those running 7.2.X.

## E.83.2. Changes

- Repair possible failure to update hint bits on disk

Under rare circumstances this oversight could lead to “could not access transaction status” failures, which qualifies it as a potential-data-loss bug.

- Ensure that hashed outer join does not miss tuples

Very large left joins using a hash join plan could fail to output unmatched left-side rows given just the right data distribution.

- Disallow running `pg_ctl` as root

This is to guard against any possible security issues.

- Avoid using temp files in `/tmp` in `make_oidjoins_check`

This has been reported as a security issue, though it's hardly worthy of concern since there is no reason for non-developers to use this script anyway.

- Update to newer versions of Bison

## **E.84. Release 7.2.5**

**Release date:** 2004-08-16

This release contains a variety of fixes from 7.2.4.

### **E.84.1. Migration to Version 7.2.5**

A dump/restore is not required for those running 7.2.X.

### **E.84.2. Changes**

- Prevent possible loss of committed transactions during crash

Due to insufficient interlocking between transaction commit and checkpointing, it was possible for transactions committed just before the most recent checkpoint to be lost, in whole or in part, following a database crash and restart. This is a serious bug that has existed since PostgreSQL 7.1.

- Fix corner case for btree search in parallel with first root page split
- Fix buffer overrun in `to_ascii` (Guido Notari)
- Fix core dump in deadlock detection on machines where `char` is unsigned
- Fix failure to respond to `pg_ctl stop -m fast` after `Async_NotifyHandler` runs
- Repair memory leaks in `pg_dump`
- Avoid conflict with system definition of `isblank()` function or macro

## **E.85. Release 7.2.4**

**Release date:** 2003-01-30

This release contains a variety of fixes for version 7.2.3, including fixes to prevent possible data loss.

## E.85.1. Migration to Version 7.2.4

A dump/restore is *not* required for those running version 7.2.\*.

## E.85.2. Changes

- Fix some additional cases of VACUUM "No one parent tuple was found" error
- Prevent VACUUM from being called inside a function (Bruce)
- Ensure pg\_clog updates are sync'd to disk before marking checkpoint complete
- Avoid integer overflow during large hash joins
- Make GROUP commands work when pg\_group.grolist is large enough to be toasted
- Fix errors in datetime tables; some timezone names weren't being recognized
- Fix integer overflows in circle\_poly(), path\_encode(), path\_add() (Neil)
- Repair long-standing logic errors in lseg\_eq(), lseg\_ne(), lseg\_center()

## E.86. Release 7.2.3

**Release date:** 2002-10-01

This release contains a variety of fixes for version 7.2.2, including fixes to prevent possible data loss.

## E.86.1. Migration to Version 7.2.3

A dump/restore is *not* required for those running version 7.2.\*.

## E.86.2. Changes

- Prevent possible compressed transaction log loss (Tom)
- Prevent non-superuser from increasing most recent vacuum info (Tom)
- Handle pre-1970 date values in newer versions of glibc (Tom)
- Fix possible hang during server shutdown
- Prevent spinlock hangs on SMP PPC machines (Tomoyuki Nijima)
- Fix pg\_dump to properly dump FULL JOIN USING (Tom)

## E.87. Release 7.2.2

**Release date:** 2002-08-23

This release contains a variety of fixes for version 7.2.1.

### E.87.1. Migration to Version 7.2.2

A dump/restore is *not* required for those running version 7.2.\*.

### E.87.2. Changes

- Allow EXECUTE of "CREATE TABLE AS ... SELECT" in PL/pgSQL (Tom)
- Fix for compressed transaction log id wraparound (Tom)
- Fix PQescapeBytea/PQunescapeBytea so that they handle bytes > 0x7f (Tatsuo)
- Fix for psql and pg\_dump crashing when invoked with non-existent long options (Tatsuo)
- Fix crash when invoking geometric operators (Tom)
- Allow OPEN cursor(args) (Tom)
- Fix for rtree\_gist index build (Teodor)
- Fix for dumping user-defined aggregates (Tom)
- contrib/intarray fixes (Oleg)
- Fix for complex UNION/EXCEPT/INTERSECT queries using parens (Tom)
- Fix to pg\_convert (Tatsuo)
- Fix for crash with long DATA strings (Thomas, Neil)
- Fix for repeat(), lpad(), rpad() and long strings (Neil)

## E.88. Release 7.2.1

**Release date:** 2002-03-21

This release contains a variety of fixes for version 7.2.

## E.88.1. Migration to Version 7.2.1

A dump/restore is *not* required for those running version 7.2.

## E.88.2. Changes

- Ensure that sequence counters do not go backwards after a crash (Tom)
- Fix pgaccess kanji-conversion key binding (Tatsuo)
- Optimizer improvements (Tom)
- Cash I/O improvements (Tom)
- New Russian FAQ
- Compile fix for missing AuthBlockSig (Heiko)
- Additional time zones and time zone fixes (Thomas)
- Allow psql \connect to handle mixed case database and user names (Tom)
- Return proper OID on command completion even with ON INSERT rules (Tom)
- Allow COPY FROM to use 8-bit DELIMITERS (Tatsuo)
- Fix bug in extract/date\_part for milliseconds/microseconds (Tatsuo)
- Improve handling of multiple UNIONs with different lengths (Tom)
- contrib/btree\_gist improvements (Teodor Sigaev)
- contrib/tsearch dictionary improvements, see README.tsearch for an additional installation step (Thomas T. Thai, Teodor Sigaev)
- Fix for array subscripts handling (Tom)
- Allow EXECUTE of "CREATE TABLE AS ... SELECT" in PL/pgSQL (Tom)

## E.89. Release 7.2

**Release date:** 2002-02-04

### E.89.1. Overview

This release improves PostgreSQL for use in high-volume applications.

Major changes in this release:

## VACUUM

Vacuuming no longer locks tables, thus allowing normal user access during the vacuum. A new `VACUUM FULL` command does old-style vacuum by locking the table and shrinking the on-disk copy of the table.

## Transactions

There is no longer a problem with installations that exceed four billion transactions.

## OIDs

OIDs are now optional. Users can now create tables without OIDs for cases where OID usage is excessive.

## Optimizer

The system now computes histogram column statistics during `ANALYZE`, allowing much better optimizer choices.

## Security

A new MD5 encryption option allows more secure storage and transfer of passwords. A new Unix-domain socket authentication option is available on Linux and BSD systems.

## Statistics

Administrators can use the new table access statistics module to get fine-grained information about table and index usage.

## Internationalization

Program and library messages can now be displayed in several languages.

## E.89.2. Migration to Version 7.2

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

Observe the following incompatibilities:

- The semantics of the `VACUUM` command have changed in this release. You might wish to update your maintenance procedures accordingly.
- In this release, comparisons using `= NULL` will always return false (or `NULL`, more precisely). Previous releases automatically transformed this syntax to `IS NULL`. The old behavior can be re-enabled using a `postgresql.conf` parameter.
- The `pg_hba.conf` and `pg_ident.conf` configuration is now only reloaded after receiving a `SIGHUP` signal, not with each connection.
- The function `octet_length()` now returns the uncompressed data length.
- The date/time value `'current'` is no longer available. You will need to rewrite your applications.
- The `timestamp()`, `time()`, and `interval()` functions are no longer available. Instead of `timestamp()`, use `timestamp 'string'` or `CAST`.

The `SELECT ... LIMIT #, #` syntax will be removed in the next release. You should change your queries to use separate `LIMIT` and `OFFSET` clauses, e.g. `LIMIT 10 OFFSET 20`.

## **E.89.3. Changes**

### **E.89.3.1. Server Operation**

- Create temporary files in a separate directory (Bruce)
- Delete orphaned temporary files on postmaster startup (Bruce)
- Added unique indexes to some system tables (Tom)
- System table operator reorganization (Oleg Bartunov, Teodor Sigaev, Tom)
- Renamed pg\_log to pg\_clog (Tom)
- Enable SIGTERM, SIGQUIT to kill backends (Jan)
- Removed compile-time limit on number of backends (Tom)
- Better cleanup for semaphore resource failure (Tatsuo, Tom)
- Allow safe transaction ID wraparound (Tom)
- Removed OIDs from some system tables (Tom)
- Removed "triggered data change violation" error check (Tom)
- SPI portal creation of prepared/saved plans (Jan)
- Allow SPI column functions to work for system columns (Tom)
- Long value compression improvement (Tom)
- Statistics collector for table, index access (Jan)
- Truncate extra-long sequence names to a reasonable value (Tom)
- Measure transaction times in milliseconds (Thomas)
- Fix TID sequential scans (Hiroshi)
- Superuser ID now fixed at 1 (Peter E)
- New pg\_ctl "reload" option (Tom)

### **E.89.3.2. Performance**

- Optimizer improvements (Tom)
- New histogram column statistics for optimizer (Tom)
- Reuse write-ahead log files rather than discarding them (Tom)
- Cache improvements (Tom)
- IS NULL, IS NOT NULL optimizer improvement (Tom)
- Improve lock manager to reduce lock contention (Tom)
- Keep relcache entries for index access support functions (Tom)
- Allow better selectivity with NaN and infinities in NUMERIC (Tom)

- R-tree performance improvements (Kenneth Been)
- B-tree splits more efficient (Tom)

### **E.89.3.3. Privileges**

- Change UPDATE, DELETE privileges to be distinct (Peter E)
- New REFERENCES, TRIGGER privileges (Peter E)
- Allow GRANT/REVOKE to/from more than one user at a time (Peter E)
- New has\_table\_privilege() function (Joe Conway)
- Allow non-superuser to vacuum database (Tom)
- New SET SESSION AUTHORIZATION command (Peter E)
- Fix bug in privilege modifications on newly created tables (Tom)
- Disallow access to pg\_statistic for non-superuser, add user-accessible views (Tom)

### **E.89.3.4. Client Authentication**

- Fork postmaster before doing authentication to prevent hangs (Peter E)
- Add ident authentication over Unix domain sockets on Linux, \*BSD (Helge Bahmann, Oliver Elphick, Teodor Sigaev, Bruce)
- Add a password authentication method that uses MD5 encryption (Bruce)
- Allow encryption of stored passwords using MD5 (Bruce)
- PAM authentication (Dominic J. Eidson)
- Load pg\_hba.conf and pg\_ident.conf only on startup and SIGHUP (Bruce)

### **E.89.3.5. Server Configuration**

- Interpretation of some time zone abbreviations as Australian rather than North American now settable at run time (Bruce)
- New parameter to set default transaction isolation level (Peter E)
- New parameter to enable conversion of "expr = NULL" into "expr IS NULL", off by default (Peter E)
- New parameter to control memory usage by VACUUM (Tom)
- New parameter to set client authentication timeout (Tom)
- New parameter to set maximum number of open files (Tom)

### E.89.3.6. Queries

- Statements added by INSERT rules now execute after the INSERT (Jan)
- Prevent unadorned relation names in target list (Bruce)
- NULLs now sort after all normal values in ORDER BY (Tom)
- New IS UNKNOWN, IS NOT UNKNOWN Boolean tests (Tom)
- New SHARE UPDATE EXCLUSIVE lock mode (Tom)
- New EXPLAIN ANALYZE command that shows run times and row counts (Martijn van Oosterhout)
- Fix problem with LIMIT and subqueries (Tom)
- Fix for LIMIT, DISTINCT ON pushed into subqueries (Tom)
- Fix nested EXCEPT/INTERSECT (Tom)

### E.89.3.7. Schema Manipulation

- Fix SERIAL in temporary tables (Bruce)
- Allow temporary sequences (Bruce)
- Sequences now use int8 internally (Tom)
- New SERIAL8 creates int8 columns with sequences, default still SERIAL4 (Tom)
- Make OIDs optional using WITHOUT OIDS (Tom)
- Add %TYPE syntax to CREATE TYPE (Ian Lance Taylor)
- Add ALTER TABLE / DROP CONSTRAINT for CHECK constraints (Christopher Kings-Lynne)
- New CREATE OR REPLACE FUNCTION to alter existing function (preserving the function OID) (Gavin Sherry)
- Add ALTER TABLE / ADD [ UNIQUE | PRIMARY ] (Christopher Kings-Lynne)
- Allow column renaming in views
- Make ALTER TABLE / RENAME COLUMN update column names of indexes (Brent Verner)
- Fix for ALTER TABLE / ADD CONSTRAINT ... CHECK with inherited tables (Stephan Szabo)
- ALTER TABLE RENAME update foreign-key trigger arguments correctly (Brent Verner)
- DROP AGGREGATE and COMMENT ON AGGREGATE now accept an aggtype (Tom)
- Add automatic return type data casting for SQL functions (Tom)
- Allow GiST indexes to handle NULLs and multikey indexes (Oleg Bartunov, Teodor Sigaev, Tom)
- Enable partial indexes (Martijn van Oosterhout)

### E.89.3.8. Utility Commands

- Add RESET ALL, SHOW ALL (Marko Kreen)
- CREATE/ALTER USER/GROUP now allow options in any order (Vince)
- Add LOCK A, B, C functionality (Neil Padgett)
- New ENCRYPTED/UNENCRYPTED option to CREATE/ALTER USER (Bruce)
- New light-weight VACUUM does not lock table; old semantics are available as VACUUM FULL (Tom)
- Disable COPY TO/FROM on views (Bruce)
- COPY DELIMITERS string must be exactly one character (Tom)
- VACUUM warning about index tuples fewer than heap now only appears when appropriate (Martijn van Oosterhout)
- Fix privilege checks for CREATE INDEX (Tom)
- Disallow inappropriate use of CREATE/DROP INDEX/TRIGGER/VIEW (Tom)

### E.89.3.9. Data Types and Functions

- SUM(), AVG(), COUNT() now uses int8 internally for speed (Tom)
- Add convert(), convert2() (Tatsuo)
- New function bit\_length() (Peter E)
- Make the "n" in CHAR(n)/VARCHAR(n) represents letters, not bytes (Tatsuo)
- CHAR(), VARCHAR() now reject strings that are too long (Peter E)
- BIT VARYING now rejects bit strings that are too long (Peter E)
- BIT now rejects bit strings that do not match declared size (Peter E)
- INET, CIDR text conversion functions (Alex Pilosov)
- INET, CIDR operators << and <<= indexable (Alex Pilosov)
- Bytea \### now requires valid three digit octal number
- Bytea comparison improvements, now supports =, <>, >, >=, <, and <=
- Bytea now supports B-tree indexes
- Bytea now supports LIKE, LIKE...ESCAPE, NOT LIKE, NOT LIKE...ESCAPE
- Bytea now supports concatenation
- New bytea functions: position, substring, trim, btrim, and length
- New encode() function mode, "escaped", converts minimally escaped bytea to/from text
- Add pg\_database\_encoding\_max\_length() (Tatsuo)
- Add pg\_client\_encoding() function (Tatsuo)
- now() returns time with millisecond precision (Thomas)

- New `TIMESTAMP WITHOUT TIMEZONE` data type (Thomas)
- Add ISO date/time specification with "T", yyyy-mm-ddThh:mm:ss (Thomas)
- New `xid/int` comparison functions (Hiroshi)
- Add precision to `TIME`, `TIMESTAMP`, and `INTERVAL` data types (Thomas)
- Modify type coercion logic to attempt binary-compatible functions first (Tom)
- New `encode()` function installed by default (Marko Kreen)
- Improved `to_*`() conversion functions (Karel Zak)
- Optimize `LIKE/ILIKE` when using single-byte encodings (Tatsuo)
- New functions in `contrib/pgcrypto`: `crypt()`, `hmac()`, `encrypt()`, `gen_salt()` (Marko Kreen)
- Correct description of `translate()` function (Bruce)
- Add `INTERVAL` argument for `SET TIME ZONE` (Thomas)
- Add `INTERVAL YEAR TO MONTH` (etc.) syntax (Thomas)
- Optimize length functions when using single-byte encodings (Tatsuo)
- Fix `path_inter`, `path_distance`, `path_length`, `dist_ppath` to handle closed paths (Curtis Barrett, Tom)
- `octet_length(text)` now returns non-compressed length (Tatsuo, Bruce)
- Handle "July" full name in date/time literals (Greg Sabino Mullane)
- Some `datatype()` function calls now evaluated differently
- Add support for Julian and ISO time specifications (Thomas)

### **E.89.3.10. Internationalization**

- National language support in `psql`, `pg_dump`, `libpq`, and `server` (Peter E)
- Message translations in Chinese (simplified, traditional), Czech, French, German, Hungarian, Russian, Swedish (Peter E, Serguei A. Mokhov, Karel Zak, Weiping He, Zhenbang Wei, Kovacs Zoltan)
- Make `trim`, `ltrim`, `rtrim`, `btrim`, `lpad`, `rpadd`, `translate` multibyte aware (Tatsuo)
- Add `LATIN5,6,7,8,9,10` support (Tatsuo)
- Add `ISO 8859-5,6,7,8` support (Tatsuo)
- Correct `LATIN5` to mean `ISO-8859-9`, not `ISO-8859-5` (Tatsuo)
- Make `mic2ascii()` non-ASCII aware (Tatsuo)
- Reject invalid multibyte character sequences (Tatsuo)

### **E.89.3.11. PL/pgSQL**

- Now uses portals for `SELECT` loops, allowing huge result sets (Jan)
- `CURSOR` and `REFCURSOR` support (Jan)

- Can now return open cursors (Jan)
- Add ELSEIF (Klaus Reger)
- Improve PL/pgSQL error reporting, including location of error (Tom)
- Allow IS or FOR key words in cursor declaration, for compatibility (Bruce)
- Fix for SELECT ... FOR UPDATE (Tom)
- Fix for PERFORM returning multiple rows (Tom)
- Make PL/pgSQL use the server's type coercion code (Tom)
- Memory leak fix (Jan, Tom)
- Make trailing semicolon optional (Tom)

### **E.89.3.12. PL/Perl**

- New untrusted PL/Perl (Alex Pilosov)
- PL/Perl is now built on some platforms even if libperl is not shared (Peter E)

### **E.89.3.13. PL/Tcl**

- Now reports errorInfo (Vsevolod Lobko)
- Add spi\_lastoid function (bob@redivi.com)

### **E.89.3.14. PL/Python**

- ...is new (Andrew Bosma)

### **E.89.3.15. psql**

- \d displays indexes in unique, primary groupings (Christopher Kings-Lynne)
- Allow trailing semicolons in backslash commands (Greg Sabino Mullane)
- Read password from /dev/tty if possible
- Force new password prompt when changing user and database (Tatsuo, Tom)
- Format the correct number of columns for Unicode (Patrice)

### **E.89.3.16. libpq**

- New function PQescapeString() to escape quotes in command strings (Florian Weimer)

- New function PQescapeBytea() escapes binary strings for use as SQL string literals

### **E.89.3.17. JDBC**

- Return OID of INSERT (Ken K)
- Handle more data types (Ken K)
- Handle single quotes and newlines in strings (Ken K)
- Handle NULL variables (Ken K)
- Fix for time zone handling (Barry Lind)
- Improved Druid support
- Allow eight-bit characters with non-multibyte server (Barry Lind)
- Support BIT, BINARY types (Ned Wolpert)
- Reduce memory usage (Michael Stephens, Dave Cramer)
- Update DatabaseMetaData (Peter E)
- Add DatabaseMetaData.getCatalogs() (Peter E)
- Encoding fixes (Anders Bengtsson)
- Get/setCatalog methods (Jason Davies)
- DatabaseMetaData.getColumns() now returns column defaults (Jason Davies)
- DatabaseMetaData.getColumns() performance improvement (Jeroen van Vianen)
- Some JDBC1 and JDBC2 merging (Anders Bengtsson)
- Transaction performance improvements (Barry Lind)
- Array fixes (Greg Zoller)
- Serialize addition
- Fix batch processing (Rene Pijlman)
- ExecSQL method reorganization (Anders Bengtsson)
- GetColumn() fixes (Jeroen van Vianen)
- Fix isWriteable() function (Rene Pijlman)
- Improved passage of JDBC2 conformance tests (Rene Pijlman)
- Add bytea type capability (Barry Lind)
- Add isNullable() (Rene Pijlman)
- JDBC date/time test suite fixes (Liam Stewart)
- Fix for SELECT 'id' AS xxx FROM table (Dave Cramer)
- Fix DatabaseMetaData to show precision properly (Mark Lillywhite)
- New getImported/getExported keys (Jason Davies)
- MD5 password encryption support (Jeremy Wohl)

- Fix to actually use type cache (Ned Wolpert)

### **E.89.3.18. ODBC**

- Remove query size limit (Hiroshi)
- Remove text field size limit (Hiroshi)
- Fix for SQLPrimaryKeys in multibyte mode (Hiroshi)
- Allow ODBC procedure calls (Hiroshi)
- Improve boolean handing (Aidan Mountford)
- Most configuration options now settable via DSN (Hiroshi)
- Multibyte, performance fixes (Hiroshi)
- Allow driver to be used with iODBC or unixODBC (Peter E)
- MD5 password encryption support (Bruce)
- Add more compatibility functions to odbc.sql (Peter E)

### **E.89.3.19. ECPG**

- EXECUTE ... INTO implemented (Christof Petig)
- Multiple row descriptor support (e.g. CARDINALITY) (Christof Petig)
- Fix for GRANT parameters (Lee Kindness)
- Fix INITIALLY DEFERRED bug
- Various bug fixes (Michael, Christof Petig)
- Auto allocation for indicator variable arrays (int \*ind\_p=NULL)
- Auto allocation for string arrays (char \*\*foo\_pp=NULL)
- ECPGfree\_auto\_mem fixed
- All function names with external linkage are now prefixed by ECPG
- Fixes for arrays of structures (Michael)

### **E.89.3.20. Misc. Interfaces**

- Python fix fetchone() (Gerhard Haring)
- Use UTF, Unicode in Tcl where appropriate (Vsevolod Lobko, Reinhard Max)
- Add Tcl COPY TO/FROM (ljb)
- Prevent output of default index op class in pg\_dump (Tom)
- Fix libpgeasy memory leak (Bruce)

### **E.89.3.21. Build and Install**

- Configure, dynamic loader, and shared library fixes (Peter E)
- Fixes in QNX 4 port (Bernd Tegge)
- Fixes in Cygwin and Windows ports (Jason Tishler, Gerhard Haring, Dmitry Yurtaev, Darko Prenosil, Mikhail Terekhov)
- Fix for Windows socket communication failures (Magnus, Mikhail Terekhov)
- Hurd compile fix (Oliver Elphick)
- BeOS fixes (Cyril Velter)
- Remove configure --enable-unicode-conversion, now enabled by multibyte (Tatsuo)
- AIX fixes (Tatsuo, Andreas)
- Fix parallel make (Peter E)
- Install SQL language manual pages into OS-specific directories (Peter E)
- Rename config.h to pg\_config.h (Peter E)
- Reorganize installation layout of header files (Peter E)

### **E.89.3.22. Source Code**

- Remove SEP\_CHAR (Bruce)
- New GUC hooks (Tom)
- Merge GUC and command line handling (Marko Kreen)
- Remove EXTEND INDEX (Martijn van Oosterhout, Tom)
- New pgjindent utility to indent java code (Bruce)
- Remove define of true/false when compiling under C++ (Leandro Fanzone, Tom)
- pgindent fixes (Bruce, Tom)
- Replace strcasecmp() with strcmp() where appropriate (Peter E)
- Dynahash portability improvements (Tom)
- Add 'volatile' usage in spinlock structures
- Improve signal handling logic (Tom)

### **E.89.3.23. Contrib**

- New contrib/rtree\_gist (Oleg Bartunov, Teodor Sigaev)
- New contrib/tsearch full-text indexing (Oleg, Teodor Sigaev)
- Add contrib/dblink for remote database access (Joe Conway)

- contrib/ora2pg Oracle conversion utility (Gilles Darold)
- contrib/xml XML conversion utility (John Gray)
- contrib/fulltextindex fixes (Christopher Kings-Lynne)
- New contrib/fuzzystrmatch with levenshtein and metaphone, soundex merged (Joe Conway)
- Add contrib/intarray boolean queries, binary search, fixes (Oleg Bartunov)
- New pg\_upgrade utility (Bruce)
- Add new pg\_resetxlog options (Bruce, Tom)

## E.90. Release 7.1.3

**Release date:** 2001-08-15

### E.90.1. Migration to Version 7.1.3

A dump/restore is *not* required for those running 7.1.X.

### E.90.2. Changes

Remove unused WAL segments of large transactions (Tom)  
Multiaction rule fix (Tom)  
PL/pgSQL memory allocation fix (Jan)  
VACUUM buffer fix (Tom)  
Regression test fixes (Tom)  
pg\_dump fixes for GRANT/REVOKE/comments on views, user-defined types (Tom)  
Fix subselects with DISTINCT ON or LIMIT (Tom)  
BeOS fix  
Disable COPY TO/FROM a view (Tom)  
Cygwin build (Jason Tishler)

## E.91. Release 7.1.2

**Release date:** 2001-05-11

This has one fix from 7.1.1.

### E.91.1. Migration to Version 7.1.2

A dump/restore is *not* required for those running 7.1.X.

### E.91.2. Changes

Fix PL/pgSQL SELECTs when returning no rows  
Fix for psql backslash core dump  
Referential integrity privilege fix  
Optimizer fixes  
pg\_dump cleanups

## E.92. Release 7.1.1

**Release date:** 2001-05-05

This has a variety of fixes from 7.1.

### E.92.1. Migration to Version 7.1.1

A dump/restore is *not* required for those running 7.1.

### E.92.2. Changes

Fix for numeric MODULO operator (Tom)  
pg\_dump fixes (Philip)  
pg\_dump can dump 7.0 databases (Philip)  
readline 4.2 fixes (Peter E)  
JOIN fixes (Tom)  
AIX, MSWIN, VAX, N32K fixes (Tom)  
Multibytes fixes (Tom)  
Unicode fixes (Tatsuo)  
Optimizer improvements (Tom)  
Fix for whole rows in functions (Tom)  
Fix for pg\_ctl and option strings with spaces (Peter E)  
ODBC fixes (Hiroshi)

EXTRACT can now take string argument (Thomas)  
Python fixes (Darcy)

## E.93. Release 7.1

**Release date:** 2001-04-13

This release focuses on removing limitations that have existed in the PostgreSQL code for many years.

Major changes in this release:

### Write-ahead Log (WAL)

To maintain database consistency in case of an operating system crash, previous releases of PostgreSQL have forced all data modifications to disk before each transaction commit. With WAL, only one log file must be flushed to disk, greatly improving performance. If you have been using `-F` in previous releases to disable disk flushes, you might want to consider discontinuing its use.

### TOAST

TOAST - Previous releases had a compiled-in row length limit, typically 8k - 32k. This limit made storage of long text fields difficult. With TOAST, long rows of any length can be stored with good performance.

### Outer Joins

We now support outer joins. The UNION/NOT IN workaround for outer joins is no longer required. We use the SQL92 outer join syntax.

### Function Manager

The previous C function manager did not handle null values properly, nor did it support 64-bit CPU's (Alpha). The new function manager does. You can continue using your old custom functions, but you might want to rewrite them in the future to use the new function manager call interface.

### Complex Queries

A large number of complex queries that were unsupported in previous releases now work. Many combinations of views, aggregates, UNION, LIMIT, cursors, subqueries, and inherited tables now work properly. Inherited tables are now accessed by default. Subqueries in FROM are now supported.

## E.93.1. Migration to Version 7.1

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release.

## E.93.2. Changes

### Bug Fixes

-----

Many multibyte/Unicode/locale fixes (Tatsuo and others)  
 More reliable ALTER TABLE RENAME (Tom)  
 Kerberos V fixes (David Wragg)  
 Fix for INSERT INTO...SELECT where targetlist has subqueries (Tom)  
 Prompt username/password on standard error (Bruce)  
 Large objects inv\_read/inv\_write fixes (Tom)  
 Fixes for to\_char(), to\_date(), to\_ascii(), and to\_timestamp() (Karel, Daniel Baldoni)  
 Prevent query expressions from leaking memory (Tom)  
 Allow UPDATE of arrays elements (Tom)  
 Wake up lock waiters during cancel (Hiroshi)  
 Fix rare cursor crash when using hash join (Tom)  
 Fix for DROP TABLE/INDEX in rolled-back transaction (Hiroshi)  
 Fix psql crash from \l+ if MULTIBYTE enabled (Peter E)  
 Fix truncation of rule names during CREATE VIEW (Ross Reedstrom)  
 Fix PL/perl (Alex Kapranoff)  
 Disallow LOCK on views (Mark Hollomon)  
 Disallow INSERT/UPDATE/DELETE on views (Mark Hollomon)  
 Disallow DROP RULE, CREATE INDEX, TRUNCATE on views (Mark Hollomon)  
 Allow PL/pgSQL accept non-ASCII identifiers (Tatsuo)  
 Allow views to properly handle GROUP BY, aggregates, DISTINCT (Tom)  
 Fix rare failure with TRUNCATE command (Tom)  
 Allow UNION/INTERSECT/EXCEPT to be used with ALL, subqueries, views, DISTINCT, ORDER BY, SELECT...INTO (Tom)  
 Fix parser failures during aborted transactions (Tom)  
 Allow temporary relations to properly clean up indexes (Bruce)  
 Fix VACUUM problem with moving rows in same page (Tom)  
 Modify pg\_dump to better handle user-defined items in template1 (Philip)  
 Allow LIMIT in VIEW (Tom)  
 Require cursor FETCH to honor LIMIT (Tom)  
 Allow PRIMARY/FOREIGN Key definitions on inherited columns (Stephan)  
 Allow ORDER BY, LIMIT in subqueries (Tom)  
 Allow UNION in CREATE RULE (Tom)  
 Make ALTER/DROP TABLE rollback-able (Vadim, Tom)  
 Store initdb collation in pg\_control so collation cannot be changed (Tom)  
 Fix INSERT...SELECT with rules (Tom)  
 Fix FOR UPDATE inside views and subselects (Tom)  
 Fix OVERLAPS operators conform to SQL92 spec regarding NULLs (Tom)  
 Fix lpad() and rpad() to handle length less than input string (Tom)  
 Fix use of NOTIFY in some rules (Tom)  
 Overhaul btree code (Tom)  
 Fix NOT NULL use in Pl/pgSQL variables (Tom)  
 Overhaul GIST code (Oleg)  
 Fix CLUSTER to preserve constraints and column default (Tom)  
 Improved deadlock detection handling (Tom)  
 Allow multiple SERIAL columns in a table (Tom)  
 Prevent occasional index corruption (Vadim)

Enhancements

-----

Add OUTER JOINS (Tom)  
Function manager overhaul (Tom)  
Allow ALTER TABLE RENAME on indexes (Tom)  
Improve CLUSTER (Tom)  
Improve ps status display for more platforms (Peter E, Marc)  
Improve CREATE FUNCTION failure message (Ross)  
JDBC improvements (Peter, Travis Bauer, Christopher Cain, William Webber, Gunnar)  
Grand Unified Configuration scheme/GUC. Many options can now be set in data/postgresql.conf, postmaster/postgres flags, or SET commands (Peter E)  
Improved handling of file descriptor cache (Tom)  
New warning code about auto-created table alias entries (Bruce)  
Overhaul initdb process (Tom, Peter E)  
Overhaul of inherited tables; inherited tables now accessed by default; new ONLY key word prevents it (Chris Bitmead, Tom)  
ODBC cleanups/improvements (Nick Gorham, Stephan Szabo, Zoltan Kovacs, Michael Fork)  
Allow renaming of temp tables (Tom)  
Overhaul memory manager contexts (Tom)  
pg\_dumpall uses CREATE USER or CREATE GROUP rather using COPY (Peter E)  
Overhaul pg\_dump (Philip Warner)  
Allow pg\_hba.conf secondary password file to specify only username (Peter E)  
Allow TEMPORARY or TEMP key word when creating temporary tables (Bruce)  
New memory leak checker (Karel)  
New SET SESSION CHARACTERISTICS (Thomas)  
Allow nested block comments (Thomas)  
Add WITHOUT TIME ZONE type qualifier (Thomas)  
New ALTER TABLE ADD CONSTRAINT (Stephan)  
Use NUMERIC accumulators for INTEGER aggregates (Tom)  
Overhaul aggregate code (Tom)  
New VARIANCE and STDDEV() aggregates  
Improve dependency ordering of pg\_dump (Philip)  
New pg\_restore command (Philip)  
New pg\_dump tar output option (Philip)  
New pg\_dump of large objects (Philip)  
New ESCAPE option to LIKE (Thomas)  
New case-insensitive LIKE - ILIKE (Thomas)  
Allow functional indexes to use binary-compatible type (Tom)  
Allow SQL functions to be used in more contexts (Tom)  
New pg\_config utility (Peter E)  
New PL/pgSQL EXECUTE command which allows dynamic SQL and utility statements (Jan)  
New PL/pgSQL GET DIAGNOSTICS statement for SPI value access (Jan)  
New quote\_identifiers() and quote\_literal() functions (Jan)  
New ALTER TABLE table OWNER TO user command (Mark Hollomon)  
Allow subselects in FROM, i.e. FROM (SELECT ...) [AS] alias (Tom)  
Update PyGreSQL to version 3.1 (D'Arcy)  
Store tables as files named by OID (Vadim)  
New SQL function setval(seq,val,bool) for use in pg\_dump (Philip)  
Require DROP VIEW to remove views, no DROP TABLE (Mark)  
Allow DROP VIEW view1, view2 (Mark)

Allow multiple objects in DROP INDEX, DROP RULE, and DROP TYPE (Tom)  
Allow automatic conversion to/from Unicode (Tatsuo, Eiji)  
New /contrib/pgcrypto hashing functions (Marko Kreen)  
New pg\_dumpall --globals-only option (Peter E)  
New CHECKPOINT command for WAL which creates new WAL log file (Vadim)  
New AT TIME ZONE syntax (Thomas)  
Allow location of Unix domain socket to be configurable (David J. MacKenzie)  
Allow postmaster to listen on a specific IP address (David J. MacKenzie)  
Allow socket path name to be specified in hostname by using leading slash  
(David J. MacKenzie)  
Allow CREATE DATABASE to specify template database (Tom)  
New utility to convert MySQL schema dumps to SQL92 and PostgreSQL (Thomas)  
New /contrib/rserv replication toolkit (Vadim)  
New file format for COPY BINARY (Tom)  
New /contrib/oid2name to map numeric files to table names (B Palmer)  
New "idle in transaction" ps status message (Marc)  
Update to pgaccess 0.98.7 (Constantin Teodorescu)  
pg\_ctl now defaults to -w (wait) on shutdown, new -l (log) option  
Add rudimentary dependency checking to pg\_dump (Philip)

#### Types

-----  
Fix INET/CIDR type ordering and add new functions (Tom)  
Make OID behave as an unsigned type (Tom)  
Allow BIGINT as synonym for INT8 (Peter E)  
New int2 and int8 comparison operators (Tom)  
New BIT and BIT VARYING types (Adriaan Joubert, Tom, Peter E)  
CHAR() no longer faster than VARCHAR() because of TOAST (Tom)  
New GIST seg/cube examples (Gene Selkov)  
Improved round(numeric) handling (Tom)  
Fix CIDR output formatting (Tom)  
New CIDR abbrev() function (Tom)

#### Performance

-----  
Write-Ahead Log (WAL) to provide crash recovery with less performance  
overhead (Vadim)  
ANALYZE stage of VACUUM no longer exclusively locks table (Bruce)  
Reduced file seeks (Denis Perchine)  
Improve BTREE code for duplicate keys (Tom)  
Store all large objects in a single table (Denis Perchine, Tom)  
Improve memory allocation performance (Karel, Tom)

#### Source Code

-----  
New function manager call conventions (Tom)  
SGI portability fixes (David Kaelbling)  
New configure --enable-syslog option (Peter E)  
New BSDI README (Bruce)  
configure script moved to top level, not /src (Peter E)  
Makefile/configuration/compilation overhaul (Peter E)  
New configure --with-python option (Peter E)  
Solaris cleanups (Peter E)

Overhaul /contrib Makefiles (Karel)  
New OpenSSL configuration option (Magnus, Peter E)  
AIX fixes (Andreas)  
QNX fixes (Maurizio)  
New heap\_open(), heap\_openr() API (Tom)  
Remove colon and semi-colon operators (Thomas)  
New pg\_class.relkind value for views (Mark Hollomon)  
Rename ichar() to chr() (Karel)  
New documentation for btrim(), ascii(), chr(), repeat() (Karel)  
Fixes for NT/Cygwin (Pete Forman)  
AIX port fixes (Andreas)  
New BeOS port (David Reid, Cyril Velter)  
Add proofreader's changes to docs (Addison-Wesley, Bruce)  
New Alpha spinlock code (Adriaan Joubert, Compaq)  
UnixWare port overhaul (Peter E)  
New Darwin/MacOS X port (Peter Bierman, Bruce Hartzler)  
New FreeBSD Alpha port (Alfred)  
Overhaul shared memory segments (Tom)  
Add IBM S/390 support (Neale Ferguson)  
Moved macmanuf to /contrib (Larry Rosenman)  
Syslog improvements (Larry Rosenman)  
New template0 database that contains no user additions (Tom)  
New /contrib/cube and /contrib/seg GIST sample code (Gene Selkov)  
Allow NetBSD's libedit instead of readline (Peter)  
Improved assembly language source code format (Bruce)  
New contrib/pg\_logger  
New --template option to createdb  
New contrib/pg\_control utility (Oliver)  
New FreeBSD tools ipc\_check, start-scripts/freebsd

## E.94. Release 7.0.3

**Release date:** 2000-11-11

This has a variety of fixes from 7.0.2.

### E.94.1. Migration to Version 7.0.3

A dump/restore is *not* required for those running 7.0.\*.

## E.94.2. Changes

Jdbc fixes (Peter)  
 Large object fix (Tom)  
 Fix lean in COPY WITH OIDS leak (Tom)  
 Fix backwards-index-scan (Tom)  
 Fix SELECT ... FOR UPDATE so it checks for duplicate keys (Hiroshi)  
 Add --enable-syslog to configure (Marc)  
 Fix abort transaction at backend exit in rare cases (Tom)  
 Fix for psql \l+ when multibyte enabled (Tatsuo)  
 Allow PL/pgSQL to accept non ascii identifiers (Tatsuo)  
 Make vacuum always flush buffers (Tom)  
 Fix to allow cancel while waiting for a lock (Hiroshi)  
 Fix for memory allocation problem in user authentication code (Tom)  
 Remove bogus use of int4out() (Tom)  
 Fixes for multiple subqueries in COALESCE or BETWEEN (Tom)  
 Fix for failure of triggers on heap open in certain cases (Jeroen van Vianen)  
 Fix for erroneous selectivity of not-equals (Tom)  
 Fix for erroneous use of strcmp() (Tom)  
 Fix for bug where storage manager accesses items beyond end of file (Tom)  
 Fix to include kernel errno message in all smgr elog messages (Tom)  
 Fix for '.' not in PATH at build time (SL Baur)  
 Fix for out-of-file-descriptors error (Tom)  
 Fix to make pg\_dump dump 'iscachable' flag for functions (Tom)  
 Fix for subselect in targetlist of Append node (Tom)  
 Fix for mergejoin plans (Tom)  
 Fix TRUNCATE failure on relations with indexes (Tom)  
 Avoid database-wide restart on write error (Hiroshi)  
 Fix nodeMaterial to honor chgParam by recomputing its output (Tom)  
 Fix VACUUM problem with moving chain of update row versions when source and destination of a row version lie on the same page (Tom)  
 Fix user.c CommandCounterIncrement (Tom)  
 Fix for AM/PM boundary problem in to\_char() (Karel Zak)  
 Fix TIME aggregate handling (Tom)  
 Fix to\_char() to avoid coredump on NULL input (Tom)  
 Buffer fix (Tom)  
 Fix for inserting/copying longer multibyte strings into char() data types (Tatsuo)  
 Fix for crash of backend, on abort (Tom)

## E.95. Release 7.0.2

**Release date:** 2000-06-05

This is a repackaging of 7.0.1 with added documentation.

## E.95.1. Migration to Version 7.0.2

A dump/restore is *not* required for those running 7.\*.

## E.95.2. Changes

Added documentation to tarball.

# E.96. Release 7.0.1

**Release date:** 2000-06-01

This is a cleanup release for 7.0.

## E.96.1. Migration to Version 7.0.1

A dump/restore is *not* required for those running 7.0.

## E.96.2. Changes

Fix many CLUSTER failures (Tom)  
Allow ALTER TABLE RENAME works on indexes (Tom)  
Fix plpgsql to handle datetime->timestamp and timespan->interval (Bruce)  
New configure --with-setproctitle switch to use setproctitle() (Marc, Bruce)  
Fix the off by one errors in ResultSet from 6.5.3, and more.  
jdbc ResultSet fixes (Joseph Shraibman)  
optimizer tunings (Tom)  
Fix create user for pgaccess  
Fix for UNLISTEN failure  
IRIX fixes (David Kaelbling)  
QNX fixes (Andreas Kardos)  
Reduce COPY IN lock level (Tom)  
Change libpqeasy to use PQconnectdb() style parameters (Bruce)  
Fix pg\_dump to handle OID indexes (Tom)

Fix small memory leak (Tom)  
Solaris fix for createdb/dropdb (Tatsuo)  
Fix for non-blocking connections (Alfred Perlstein)  
Fix improper recovery after RENAME TABLE failures (Tom)  
Copy pg\_ident.conf.sample into /lib directory in install (Bruce)  
Add SJIS UDC (NEC selection IBM kanji) support (Eiji Tokuya)  
Fix too long syslog message (Tatsuo)  
Fix problem with quoted indexes that are too long (Tom)  
JDBC ResultSet.getTimestamp() fix (Gregory Krasnow & Floyd Marinescu)  
ecpg changes (Michael)

## E.97. Release 7.0

**Release date:** 2000-05-08

This release contains improvements in many areas, demonstrating the continued growth of PostgreSQL. There are more improvements and fixes in 7.0 than in any previous release. The developers have confidence that this is the best release yet; we do our best to put out only solid releases, and this one is no exception.

Major changes in this release:

### Foreign Keys

Foreign keys are now implemented, with the exception of PARTIAL MATCH foreign keys. Many users have been asking for this feature, and we are pleased to offer it.

### Optimizer Overhaul

Continuing on work started a year ago, the optimizer has been improved, allowing better query plan selection and faster performance with less memory usage.

### Updated psql

psql, our interactive terminal monitor, has been updated with a variety of new features. See the psql manual page for details.

### Join Syntax

SQL92 join syntax is now supported, though only as INNER JOIN for this release. JOIN, NATURAL JOIN, JOIN/USING, and JOIN/ON are available, as are column correlation names.

## E.97.1. Migration to Version 7.0

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release of PostgreSQL. For those upgrading from 6.5.\*, you can instead use `pg_upgrade` to upgrade to this release; however, a full dump/reload installation is always the most robust method for upgrades.

Interface and compatibility issues to consider for the new release include:

- The date/time types `datetime` and `timespan` have been superseded by the SQL92-defined types `timestamp` and `interval`. Although there has been some effort to ease the transition by allowing PostgreSQL to recognize the deprecated type names and translate them to the new type names, this mechanism cannot be completely transparent to your existing application.
- The optimizer has been substantially improved in the area of query cost estimation. In some cases, this will result in decreased query times as the optimizer makes a better choice for the preferred plan. However, in a small number of cases, usually involving pathological distributions of data, your query times might go up. If you are dealing with large amounts of data, you might want to check your queries to verify performance.
- The JDBC and ODBC interfaces have been upgraded and extended.
- The string function `CHAR_LENGTH` is now a native function. Previous versions translated this into a call to `LENGTH`, which could result in ambiguity with other types implementing `LENGTH` such as the geometric types.

## E.97.2. Changes

### Bug Fixes

-----

```
Prevent function calls exceeding maximum number of arguments (Tom)
Improve CASE construct (Tom)
Fix SELECT coalesce(f1,0) FROM int4_tbl GROUP BY f1 (Tom)
Fix SELECT sentence.words[0] FROM sentence GROUP BY sentence.words[0] (Tom)
Fix GROUP BY scan bug (Tom)
Improvements in SQL grammar processing (Tom)
Fix for views involved in INSERT ... SELECT ... (Tom)
Fix for SELECT a/2, a/2 FROM test_missing_target GROUP BY a/2 (Tom)
Fix for subselects in INSERT ... SELECT (Tom)
Prevent INSERT ... SELECT ... ORDER BY (Tom)
Fixes for relations greater than 2GB, including vacuum
Improve propagating system table changes to other backends (Tom)
Improve propagating user table changes to other backends (Tom)
Fix handling of temp tables in complex situations (Bruce, Tom)
Allow table locking at table open, improving concurrent reliability (Tom)
Properly quote sequence names in pg_dump (Ross J. Reedstrom)
Prevent DROP DATABASE while others accessing
Prevent any rows from being returned by GROUP BY if no rows processed (Tom)
Fix SELECT COUNT(1) FROM table WHERE ...' if no rows matching WHERE (Tom)
Fix pg_upgrade so it works for MVCC (Tom)
Fix for SELECT ... WHERE x IN (SELECT ... HAVING SUM(x) > 1) (Tom)
Fix for "f1 datetime DEFAULT 'now'" (Tom)
```

Fix problems with CURRENT\_DATE used in DEFAULT (Tom)  
Allow comment-only lines, and `;;;` lines too. (Tom)  
Improve recovery after failed disk writes, disk full (Hiroshi)  
Fix cases where table is mentioned in FROM but not joined (Tom)  
Allow HAVING clause without aggregate functions (Tom)  
Fix for `--` comment and no trailing newline, as seen in perl interface  
Improve pg\_dump failure error reports (Bruce)  
Allow sorts and hashes to exceed 2GB file sizes (Tom)  
Fix for pg\_dump dumping of inherited rules (Tom)  
Fix for NULL handling comparisons (Tom)  
Fix inconsistent state caused by failed CREATE/DROP commands (Hiroshi)  
Fix for dbname with dash  
Prevent DROP INDEX from interfering with other backends (Tom)  
Fix file descriptor leak in verify\_password()  
Fix for "Unable to identify an operator = \$" problem  
Fix ODBC so no segfault if CommLog and Debug enabled (Dirk Niggemann)  
Fix for recursive exit call (Massimo)  
Fix for extra-long timezones (Jeroen van Vianen)  
Make pg\_dump preserve primary key information (Peter E)  
Prevent databases with single quotes (Peter E)  
Prevent DROP DATABASE inside transaction (Peter E)  
ecpg memory leak fixes (Stephen Birch)  
Fix for SELECT null::text, SELECT int4fac(null) and SELECT 2 + (null) (Tom)  
Y2K timestamp fix (Massimo)  
Fix for VACUUM 'HEAP\_MOVED\_IN was not expected' errors (Tom)  
Fix for views with tables/columns containing spaces (Tom)  
Prevent privileges on indexes (Peter E)  
Fix for spinlock stuck problem when error is generated (Hiroshi)  
Fix ipcclean on Linux  
Fix handling of NULL constraint conditions (Tom)  
Fix memory leak in odbc driver (Nick Gorham)  
Fix for privilege check on UNION tables (Tom)  
Fix to allow SELECT 'a' LIKE 'a' (Tom)  
Fix for SELECT 1 + NULL (Tom)  
Fixes to CHAR  
Fix log() on numeric type (Tom)  
Deprecate `:'` and `;'` operators  
Allow vacuum of temporary tables  
Disallow inherited columns with the same name as new columns  
Recover or force failure when disk space is exhausted (Hiroshi)  
Fix INSERT INTO ... SELECT with AS columns matching result columns  
Fix INSERT ... SELECT ... GROUP BY groups by target columns not source columns (Tom)  
Fix CREATE TABLE test (a char(5) DEFAULT text "", b int4) with INSERT (Tom)  
Fix UNION with LIMIT  
Fix CREATE TABLE x AS SELECT 1 UNION SELECT 2  
Fix CREATE TABLE test(col char(2) DEFAULT user)  
Fix mismatched types in CREATE TABLE ... DEFAULT  
Fix SELECT \* FROM pg\_class where oid in (0,-1)  
Fix SELECT COUNT('asdf') FROM pg\_class WHERE oid=12  
Prevent user who can create databases can modifying pg\_database table (Peter E)  
Fix btree to give a useful elog when key > 1/2 (page - overhead) (Tom)  
Fix INSERT of 0.0 into DECIMAL(4,4) field (Tom)

## Enhancements

-----

New CLI interface include file sqlcli.h, based on SQL3/SQL98  
 Remove all limits on query length, row length limit still exists (Tom)  
 Update jdbc protocol to 2.0 (Jens Glaser <jens@jens.de>)  
 Add TRUNCATE command to quickly truncate relation (Mike Mascari)  
 Fix to give super user and createdb user proper update catalog rights (Peter E)  
 Allow ecpg bool variables to have NULL values (Christof)  
 Issue ecpg error if NULL value for variable with no NULL indicator (Christof)  
 Allow ^C to cancel COPY command (Massimo)  
 Add SET FSYNC and SHOW PG\_OPTIONS commands (Massimo)  
 Function name overloading for dynamically-loaded C functions (Frankpitt)  
 Add CmdTuples() to libpq++ (Vince)  
 New CREATE CONSTRAINT TRIGGER and SET CONSTRAINTS commands (Jan)  
 Allow CREATE FUNCTION/WITH clause to be used for all language types  
 configure --enable-debug adds -g (Peter E)  
 configure --disable-debug removes -g (Peter E)  
 Allow more complex default expressions (Tom)  
 First real FOREIGN KEY constraint trigger functionality (Jan)  
 Add FOREIGN KEY ... MATCH FULL ... ON DELETE CASCADE (Jan)  
 Add FOREIGN KEY ... MATCH <unspecified> referential actions (Don Baccus)  
 Allow WHERE restriction on ctid (physical heap location) (Hiroshi)  
 Move pginterface from contrib to interface directory, rename to pgeasy (Bruce)  
 Change pgeasy connectdb() parameter ordering (Bruce)  
 Require SELECT DISTINCT target list to have all ORDER BY columns (Tom)  
 Add Oracle's COMMENT ON command (Mike Mascari <mascarim@yahoo.com>)  
 libpq's PQsetNoticeProcessor function now returns previous hook (Peter E)  
 Prevent PQsetNoticeProcessor from being set to NULL (Peter E)  
 Make USING in COPY optional (Bruce)  
 Allow subselects in the target list (Tom)  
 Allow subselects on the left side of comparison operators (Tom)  
 New parallel regression test (Jan)  
 Change backend-side COPY to write files with permissions 644 not 666 (Tom)  
 Force permissions on PGDATA directory to be secure, even if it exists (Tom)  
 Added psql LASTOID variable to return last inserted oid (Peter E)  
 Allow concurrent vacuum and remove pg\_vlock vacuum lock file (Tom)  
 Add privilege check for vacuum (Peter E)  
 New libpq functions to allow asynchronous connections: PQconnectStart(),  
     PQconnectPoll(), PQresetStart(), PQresetPoll(), PQsetenvStart(),  
     PQsetenvPoll(), PQsetenvAbort (Ewan Mellor)  
 New libpq PQsetenv() function (Ewan Mellor)  
 create/alter user extension (Peter E)  
 New postmaster.pid and postmaster.opts under \$PGDATA (Tatsuo)  
 New scripts for create/drop user/db (Peter E)  
 Major psql overhaul (Peter E)  
 Add const to libpq interface (Peter E)  
 New libpq function PQoidValue (Peter E)  
 Show specific non-aggregate causing problem with GROUP BY (Tom)  
 Make changes to pg\_shadow recreate pg\_pwd file (Peter E)  
 Add aggregate(DISTINCT ...) (Tom)  
 Allow flag to control COPY input/output of NULLs (Peter E)  
 Make postgres user have a password by default (Peter E)  
 Add CREATE/ALTER/DROP GROUP (Peter E)

All administration scripts now support --long options (Peter E, Karel)  
Vacuumdb script now supports --all option (Peter E)  
ecpg new portable FETCH syntax  
Add ecpg EXEC SQL IFDEF, EXEC SQL IFNDEF, EXEC SQL ELSE, EXEC SQL ELIF  
and EXEC SQL ENDIF directives  
Add pg\_ctl script to control backend start-up (Tatsuo)  
Add postmaster.opts.default file to store start-up flags (Tatsuo)  
Allow --with-mb=SQL\_ASCII  
Increase maximum number of index keys to 16 (Bruce)  
Increase maximum number of function arguments to 16 (Bruce)  
Allow configuration of maximum number of index keys and arguments (Bruce)  
Allow unprivileged users to change their passwords (Peter E)  
Password authentication enabled; required for new users (Peter E)  
Disallow dropping a user who owns a database (Peter E)  
Change initdb option --with-mb to --enable-multibyte  
Add option for initdb to prompts for superuser password (Peter E)  
Allow complex type casts like col::numeric(9,2) and col::int2::float8 (Tom)  
Updated user interfaces on initdb, initlocation, pg\_dump, ipcclean (Peter E)  
New pg\_char\_to\_encoding() and pg\_encoding\_to\_char() functions (Tatsuo)  
libpq non-blocking mode (Alfred Perlstein)  
Improve conversion of types in casts that don't specify a length  
New plperl internal programming language (Mark Hollomon)  
Allow COPY IN to read file that do not end with a newline (Tom)  
Indicate when long identifiers are truncated (Tom)  
Allow aggregates to use type equivalency (Peter E)  
Add Oracle's to\_char(), to\_date(), to\_datetime(), to\_timestamp(), to\_number()  
conversion functions (Karel Zak <zakkr@zf.jcu.cz>)  
Add SELECT DISTINCT ON (expr [, expr ...]) targetlist ... (Tom)  
Check to be sure ORDER BY is compatible with the DISTINCT operation (Tom)  
Add NUMERIC and int8 types to ODBC  
Improve EXPLAIN results for Append, Group, Agg, Unique (Tom)  
Add ALTER TABLE ... ADD FOREIGN KEY (Stephan Szabo)  
Allow SELECT .. FOR UPDATE in PL/pgSQL (Hiroshi)  
Enable backward sequential scan even after reaching EOF (Hiroshi)  
Add btree indexing of boolean values, >= and <= (Don Baccus)  
Print current line number when COPY FROM fails (Massimo)  
Recognize POSIX time zone e.g. "PST+8" and "GMT-8" (Thomas)  
Add DEC as synonym for DECIMAL (Thomas)  
Add SESSION\_USER as SQL92 key word, same as CURRENT\_USER (Thomas)  
Implement SQL92 column aliases (aka correlation names) (Thomas)  
Implement SQL92 join syntax (Thomas)  
Make INTERVAL reserved word allowed as a column identifier (Thomas)  
Implement REINDEX command (Hiroshi)  
Accept ALL in aggregate function SUM(ALL col) (Tom)  
Prevent GROUP BY from using column aliases (Tom)  
New psql \encoding option (Tatsuo)  
Allow PQrequestCancel() to terminate when in waiting-for-lock state (Hiroshi)  
Allow negation of a negative number in all cases  
Add ecpg descriptors (Christof, Michael)  
Allow CREATE VIEW v AS SELECT f1::char(8) FROM tbl  
Allow casts with length, like foo::char(8)  
New libpq functions PQsetClientEncoding(), PQclientEncoding() (Tatsuo)  
Add support for SJIS user defined characters (Tatsuo)

Larger views/rules supported  
Make libpq's PQconndefaults() thread-safe (Tom)  
Disable // as comment to be ANSI conforming, should use -- (Tom)  
Allow column aliases on views CREATE VIEW name (collist)  
Fixes for views with subqueries (Tom)  
Allow UPDATE table SET fld = (SELECT ...) (Tom)  
SET command options no longer require quotes  
Update pgaccess to 0.98.6  
New SET SEED command  
New pg\_options.sample file  
New SET FSYNC command (Massimo)  
Allow pg\_descriptions when creating tables  
Allow pg\_descriptions when creating types, columns, and functions  
Allow psql \copy to allow delimiters (Peter E)  
Allow psql to print nulls as distinct from "" [null] (Peter E)

Types  
-----

Many array fixes (Tom)  
Allow bare column names to be subscripted as arrays (Tom)  
Improve type casting of int and float constants (Tom)  
Cleanups for int8 inputs, range checking, and type conversion (Tom)  
Fix for SELECT timespan('21:11:26'::time) (Tom)  
netmask('x.x.x.x/0') is 255.255.255.255 instead of 0.0.0.0 (Oleg Sharoiiko)  
Add btree index on NUMERIC (Jan)  
Perl fix for large objects containing NUL characters (Douglas Thomson)  
ODBC fix for large objects (free)  
Fix indexing of cidr data type  
Fix for Ethernet MAC addresses (macaddr type) comparisons  
Fix for date/time types when overflows happened in computations (Tom)  
Allow array on int8 (Peter E)  
Fix for rounding/overflow of NUMERIC type, like NUMERIC(4,4) (Tom)  
Allow NUMERIC arrays  
Fix bugs in NUMERIC ceil() and floor() functions (Tom)  
Make char\_length()/octet\_length including trailing blanks (Tom)  
Made abstime/retime use int4 instead of time\_t (Peter E)  
New lztext data type for compressed text fields  
Revise code to handle coercion of int and float constants (Tom)  
Start at new code to implement a BIT and BIT VARYING type (Adriaan Joubert)  
NUMERIC now accepts scientific notation (Tom)  
NUMERIC to int4 rounds (Tom)  
Convert float4/8 to NUMERIC properly (Tom)  
Allow type conversion with NUMERIC (Thomas)  
Make ISO date style (2000-02-16 09:33) the default (Thomas)  
Add NATIONAL CHAR [ VARYING ] (Thomas)  
Allow NUMERIC round and trunc to accept negative scales (Tom)  
New TIME WITH TIME ZONE type (Thomas)  
Add MAX()/MIN() on time type (Thomas)  
Add abs(), mod(), fac() for int8 (Thomas)  
Rename functions to round(), sqrt(), cbrt(), pow() for float8 (Thomas)  
Add transcendental math functions (e.g. sin(), acos()) for float8 (Thomas)  
Add exp() and ln() for NUMERIC type  
Rename NUMERIC power() to pow() (Thomas)

Improved TRANSLATE() function (Edwin Ramirez, Tom)  
Allow X=-Y operators (Tom)  
Allow SELECT float8(COUNT(\*))/(SELECT COUNT(\*) FROM t) FROM t GROUP BY f1; (Tom)  
Allow LOCALE to use indexes in regular expression searches (Tom)  
Allow creation of functional indexes to use default types

#### Performance

-----

Prevent exponential space consumption with many AND's and OR's (Tom)  
Collect attribute selectivity values for system columns (Tom)  
Reduce memory usage of aggregates (Tom)  
Fix for LIKE optimization to use indexes with multibyte encodings (Tom)  
Fix r-tree index optimizer selectivity (Thomas)  
Improve optimizer selectivity computations and functions (Tom)  
Optimize btree searching for cases where many equal keys exist (Tom)  
Enable fast LIKE index processing only if index present (Tom)  
Re-use free space on index pages with duplicates (Tom)  
Improve hash join processing (Tom)  
Prevent descending sort if result is already sorted (Hiroshi)  
Allow commuting of index scan query qualifications (Tom)  
Prefer index scans in cases where ORDER BY/GROUP BY is required (Tom)  
Allocate large memory requests in fix-sized chunks for performance (Tom)  
Fix vacuum's performance by reducing memory allocation requests (Tom)  
Implement constant-expression simplification (Bernard Frankpitt, Tom)  
Use secondary columns to be used to determine start of index scan (Hiroshi)  
Prevent quadruple use of disk space when doing internal sorting (Tom)  
Faster sorting by calling fewer functions (Tom)  
Create system indexes to match all system caches (Bruce, Hiroshi)  
Make system caches use system indexes (Bruce)  
Make all system indexes unique (Bruce)  
Improve pg\_statistics management for VACUUM speed improvement (Tom)  
Flush backend cache less frequently (Tom, Hiroshi)  
COPY now reuses previous memory allocation, improving performance (Tom)  
Improve optimization cost estimation (Tom)  
Improve optimizer estimate of range queries  $x > \text{lowbound}$  AND  $x < \text{highbound}$  (Tom)  
Use DNF instead of CNF where appropriate (Tom, Taral)  
Further cleanup for OR-of-AND WHERE-clauses (Tom)  
Make use of index in OR clauses ( $x = 1$  AND  $y = 2$ ) OR ( $x = 2$  AND  $y = 4$ ) (Tom)  
Smarter optimizer computations for random index page access (Tom)  
New SET variable to control optimizer costs (Tom)  
Optimizer queries based on LIMIT, OFFSET, and EXISTS qualifications (Tom)  
Reduce optimizer internal housekeeping of join paths for speedup (Tom)  
Major subquery speedup (Tom)  
Fewer fsync writes when fsync is not disabled (Tom)  
Improved LIKE optimizer estimates (Tom)  
Prevent fsync in SELECT-only queries (Vadim)  
Make index creation use psort code, because it is now faster (Tom)  
Allow creation of sort temp tables > 1 Gig

#### Source Tree Changes

-----

Fix for linux PPC compile  
New generic expression-tree-walker subroutine (Tom)

Change form() to varargform() to prevent portability problems  
Improved range checking for large integers on Alphas  
Clean up #include in /include directory (Bruce)  
Add scripts for checking includes (Bruce)  
Remove un-needed #include's from \*.c files (Bruce)  
Change #include's to use <> and "" as appropriate (Bruce)  
Enable Windows compilation of libpq  
Alpha spinlock fix from Uncle George <gatgul@voicenet.com>  
Overhaul of optimizer data structures (Tom)  
Fix to cygipc library (Yutaka Tanida)  
Allow pgsqll to work on newer Cygwin snapshots (Dan)  
New catalog version number (Tom)  
Add Linux ARM  
Rename heap\_replace to heap\_update  
Update for QNX (Dr. Andreas Kardos)  
New platform-specific regression handling (Tom)  
Rename oid8 -> oidvector and int28 -> int2vector (Bruce)  
Included all yacc and lex files into the distribution (Peter E.)  
Remove lextest, no longer needed (Peter E.)  
Fix for libpq and psql on Windows (Magnus)  
Internally change datetime and timespan into timestamp and interval (Thomas)  
Fix for plpgsql on BSD/OS  
Add SQL\_ASCII test case to the regression test (Tatsuo)  
configure --with-mb now deprecated (Tatsuo)  
NT fixes  
NetBSD fixes (Johnny C. Lam <lamj@stat.cmu.edu>)  
Fixes for Alpha compiles  
New multibyte encodings

## E.98. Release 6.5.3

**Release date:** 1999-10-13

This is basically a cleanup release for 6.5.2. We have added a new PgAccess that was missing in 6.5.2, and installed an NT-specific fix.

### E.98.1. Migration to Version 6.5.3

A dump/restore is *not* required for those running 6.5.\*.

## E.98.2. Changes

Updated version of pgaccess 0.98  
 NT-specific patch  
 Fix dumping rules on inherited tables

## E.99. Release 6.5.2

**Release date:** 1999-09-15

This is basically a cleanup release for 6.5.1. We have fixed a variety of problems reported by 6.5.1 users.

### E.99.1. Migration to Version 6.5.2

A dump/restore is *not* required for those running 6.5.\*.

### E.99.2. Changes

subselect+CASE fixes(Tom)  
 Add SHLIB\_LINK setting for solaris\_i386 and solaris\_sparc ports(Daren Sefcik)  
 Fixes for CASE in WHERE join clauses(Tom)  
 Fix BTScan abort(Tom)  
 Repair the check for redundant UNIQUE and PRIMARY KEY indexes(Thomas)  
 Improve it so that it checks for multicolumn constraints(Thomas)  
 Fix for Windows making problem with MB enabled(Hiroki Kataoka)  
 Allow BSD yacc and bison to compile pl code(Bruce)  
 Fix SET NAMES working  
 int8 fixes(Thomas)  
 Fix vacuum's memory consumption(Hiroshi,Tatsuo)  
 Reduce the total memory consumption of vacuum(Tom)  
 Fix for timestamp(datetime)  
 Rule deparsing bugfixes(Tom)  
 Fix quoting problems in mkMakefile.tcldefs.sh.in and mkMakefile.tkdefs.sh.in(Tom)  
 This is to re-use space on index pages freed by vacuum(Vadim)  
 document -x for pg\_dump(Bruce)  
 Fix for unary operators in rule deparser(Tom)  
 Comment out FileUnlink of excess segments during mdtruncate()(Tom)  
 IRIX linking fix from Yu Cao >yucao@falcon.kla-tencor.com<  
 Repair logic error in LIKE: should not return LIKE\_ABORT  
     when reach end of pattern before end of text(Tom)  
 Repair incorrect cleanup of heap memory allocation during transaction abort(Tom)

Updated version of pgaccess 0.98

## E.100. Release 6.5.1

**Release date:** 1999-07-15

This is basically a cleanup release for 6.5. We have fixed a variety of problems reported by 6.5 users.

### E.100.1. Migration to Version 6.5.1

A dump/restore is *not* required for those running 6.5.

### E.100.2. Changes

Add NT README file  
Portability fixes for linux\_ppc, IRIX, linux\_alpha, OpenBSD, alpha  
Remove QUERY\_LIMIT, use SELECT...LIMIT  
Fix for EXPLAIN on inheritance(Tom)  
Patch to allow vacuum on multiseget tables(Hiroshi)  
R-Tree optimizer selectivity fix(Tom)  
ACL file descriptor leak fix(Atsushi Ogawa)  
New expression subtree code(Tom)  
Avoid disk writes for read-only transactions(Vadim)  
Fix for removal of temp tables if last transaction was aborted(Bruce)  
Fix to prevent too large row from being created(Bruce)  
plpgsql fixes  
Allow port numbers 32k - 64k(Bruce)  
Add ^ precedence(Bruce)  
Rename sort files called pg\_temp to pg\_sorttemp(Bruce)  
Fix for microseconds in time values(Tom)  
Tutorial source cleanup  
New linux\_m68k port  
Fix for sorting of NULL's in some cases(Tom)  
Shared library dependencies fixed (Tom)  
Fixed glitches affecting GROUP BY in subselects(Tom)  
Fix some compiler warnings (Tomoaki Nishiyama)  
Add Win1250 (Czech) support (Pavel Behal)

## E.101. Release 6.5

**Release date:** 1999-06-09

This release marks a major step in the development team's mastery of the source code we inherited from Berkeley. You will see we are now easily adding major features, thanks to the increasing size and experience of our world-wide development team.

Here is a brief summary of the more notable changes:

### Multiversion concurrency control(MVCC)

This removes our old table-level locking, and replaces it with a locking system that is superior to most commercial database systems. In a traditional system, each row that is modified is locked until committed, preventing reads by other users. MVCC uses the natural multiversion nature of PostgreSQL to allow readers to continue reading consistent data during writer activity. Writers continue to use the compact `pg_log` transaction system. This is all performed without having to allocate a lock for every row like traditional database systems. So, basically, we no longer are restricted by simple table-level locking; we have something better than row-level locking.

### Hot backups from `pg_dump`

`pg_dump` takes advantage of the new MVCC features to give a consistent database dump/backup while the database stays online and available for queries.

### Numeric data type

We now have a true numeric data type, with user-specified precision.

### Temporary tables

Temporary tables are guaranteed to have unique names within a database session, and are destroyed on session exit.

### New SQL features

We now have `CASE`, `INTERSECT`, and `EXCEPT` statement support. We have new `LIMIT/OFFSET`, `SET TRANSACTION ISOLATION LEVEL`, `SELECT ... FOR UPDATE`, and an improved `LOCK TABLE` command.

### Speedups

We continue to speed up PostgreSQL, thanks to the variety of talents within our team. We have sped up memory allocation, optimization, table joins, and row transfer routines.

### Ports

We continue to expand our port list, this time including Windows NT/ix86 and NetBSD/arm32.

### Interfaces

Most interfaces have new versions, and existing functionality has been improved.

### Documentation

New and updated material is present throughout the documentation. New FAQs have been contributed for SGI and AIX platforms. The *Tutorial* has introductory information on SQL from Stefan

Simkovics. For the *User's Guide*, there are reference pages covering the postmaster and more utility programs, and a new appendix contains details on date/time behavior. The *Administrator's Guide* has a new chapter on troubleshooting from Tom Lane. And the *Programmer's Guide* has a description of query processing, also from Stefan, and details on obtaining the PostgreSQL source tree via anonymous CVS and CVSup.

## E.101.1. Migration to Version 6.5

A dump/restore using `pg_dump` is required for those wishing to migrate data from any previous release of PostgreSQL. `pg_upgrade` can *not* be used to upgrade to this release because the on-disk structure of the tables has changed compared to previous releases.

The new Multiversion Concurrency Control (MVCC) features can give somewhat different behaviors in multiuser environments. *Read and understand the following section to ensure that your existing applications will give you the behavior you need.*

### E.101.1.1. Multiversion Concurrency Control

Because readers in 6.5 don't lock data, regardless of transaction isolation level, data read by one transaction can be overwritten by another. In other words, if a row is returned by `SELECT` it doesn't mean that this row really exists at the time it is returned (i.e. sometime after the statement or transaction began) nor that the row is protected from being deleted or updated by concurrent transactions before the current transaction does a commit or rollback.

To ensure the actual existence of a row and protect it against concurrent updates one must use `SELECT FOR UPDATE` or an appropriate `LOCK TABLE` statement. This should be taken into account when porting applications from previous releases of PostgreSQL and other environments.

Keep the above in mind if you are using `contrib/refint.*` triggers for referential integrity. Additional techniques are required now. One way is to use `LOCK parent_table IN SHARE ROW EXCLUSIVE MODE` command if a transaction is going to update/delete a primary key and use `LOCK parent_table IN SHARE MODE` command if a transaction is going to update/insert a foreign key.

**Note:** Note that if you run a transaction in `SERIALIZABLE` mode then you must execute the `LOCK` commands above before execution of any DML statement (`SELECT/INSERT/DELETE/UPDATE/FETCH/COPY_TO`) in the transaction.

These inconveniences will disappear in the future when the ability to read dirty (uncommitted) data (regardless of isolation level) and true referential integrity will be implemented.

## E.101.2. Changes

Bug Fixes

```

-----
Fix text<->float8 and text<->float4 conversion functions(Thomas)
Fix for creating tables with mixed-case constraints(Billy)
Change exp()/pow() behavior to generate error on underflow/overflow(Jan)
Fix bug in pg_dump -z
Memory overrun cleanups(Tatsuo)
Fix for lo_import crash(Tatsuo)
Adjust handling of data type names to suppress double quotes(Thomas)
Use type coercion for matching columns and DEFAULT(Thomas)
Fix deadlock so it only checks once after one second of sleep(Bruce)
Fixes for aggregates and PL/pgsql(Hiroshi)
Fix for subquery crash(Vadim)
Fix for libpq function PQfnumber and case-insensitive names(Bahman Rafatjoo)
Fix for large object write-in-middle, no extra block, memory consumption(Tatsuo)
Fix for pg_dump -d or -D and quote special characters in INSERT
Repair serious problems with dynahash(Tom)
Fix INET/CIDR portability problems
Fix problem with selectivity error in ALTER TABLE ADD COLUMN(Bruce)
Fix executor so mergejoin of different column types works(Tom)
Fix for Alpha OR selectivity bug
Fix OR index selectivity problem(Bruce)
Fix so \d shows proper length for char()/varchar() (Ryan)
Fix tutorial code(Clark)
Improve destroyuser checking(Oliver)
Fix for Kerberos(Rodney McDuff)
Fix for dropping database while dirty buffers(Bruce)
Fix so sequence nextval() can be case-sensitive(Bruce)
Fix != operator
Drop buffers before destroying database files(Bruce)
Fix case where executor evaluates functions twice(Tatsuo)
Allow sequence nextval actions to be case-sensitive(Bruce)
Fix optimizer indexing not working for negative numbers(Bruce)
Fix for memory leak in executor with fjIsNull
Fix for aggregate memory leaks(Erik Riedel)
Allow user name containing a dash to grant privileges
Cleanup of NULL in inet types
Clean up system table bugs(Tom)
Fix problems of PAGER and \? command(Masaaki Sakaida)
Reduce default multisegment file size limit to 1GB(Peter)
Fix for dumping of CREATE OPERATOR(Tom)
Fix for backward scanning of cursors(Hiroshi Inoue)
Fix for COPY FROM STDIN when using \i(Tom)
Fix for subselect is compared inside an expression(Jan)
Fix handling of error reporting while returning rows(Tom)
Fix problems with reference to array types(Tom,Jan)
Prevent UPDATE SET oid(Jan)
Fix pg_dump so -t option can handle case-sensitive tablenamees
Fixes for GROUP BY in special cases(Tom, Jan)
Fix for memory leak in failed queries(Tom)
DEFAULT now supports mixed-case identifiers(Tom)
Fix for multisegment uses of DROP/RENAME table, indexes(Ole Gjerde)
Disable use of pg_dump with both -o and -d options(Bruce)
Allow pg_dump to properly dump group privileges(Bruce)

```

Fix GROUP BY in INSERT INTO table SELECT \* FROM table2(Jan)  
Fix for computations in views(Jan)  
Fix for aggregates on array indexes(Tom)  
Fix for DEFAULT handles single quotes in value requiring too many quotes  
Fix security problem with non-super users importing/exporting large objects(Tom)  
Rollback of transaction that creates table cleaned up properly(Tom)  
Fix to allow long table and column names to generate proper serial names(Tom)

#### Enhancements

-----

Add "vacuumdb" utility  
Speed up libpq by allocating memory better(Tom)  
EXPLAIN all indexes used(Tom)  
Implement CASE, COALESCE, NULLIF expression(Thomas)  
New pg\_dump table output format(Constantin)  
Add string min()/max() functions(Thomas)  
Extend new type coercion techniques to aggregates(Thomas)  
New moddatetime contrib(Terry)  
Update to pgaccess 0.96(Constantin)  
Add routines for single-byte "char" type(Thomas)  
Improved substr() function(Thomas)  
Improved multibyte handling(Tatsuo)  
Multiversion concurrency control/MVCC(Vadim)  
New Serialized mode(Vadim)  
Fix for tables over 2gigs(Peter)  
New SET TRANSACTION ISOLATION LEVEL(Vadim)  
New LOCK TABLE IN ... MODE(Vadim)  
Update ODBC driver(Byron)  
New NUMERIC data type(Jan)  
New SELECT FOR UPDATE(Vadim)  
Handle "NaN" and "Infinity" for input values(Jan)  
Improved date/year handling(Thomas)  
Improved handling of backend connections(Magnus)  
New options ELOG\_TIMESTAMPS and USE\_SYSLOG options for log files(Massimo)  
New TCL\_ARRAYS option(Massimo)  
New INTERSECT and EXCEPT(Stefan)  
New pg\_index.indisprimary for primary key tracking(D'Arcy)  
New pg\_dump option to allow dropping of tables before creation(Brook)  
Speedup of row output routines(Tom)  
New READ COMMITTED isolation level(Vadim)  
New TEMP tables/indexes(Bruce)  
Prevent sorting if result is already sorted(Jan)  
New memory allocation optimization(Jan)  
Allow psql to do \p\g(Bruce)  
Allow multiple rule actions(Jan)  
Added LIMIT/OFFSET functionality(Jan)  
Improve optimizer when joining a large number of tables(Bruce)  
New intro to SQL from S. Simkovics' Master's Thesis (Stefan, Thomas)  
New intro to backend processing from S. Simkovics' Master's Thesis (Stefan)  
Improved int8 support(Ryan Bradetich, Thomas, Tom)  
New routines to convert between int8 and text/varchar types(Thomas)  
New bushy plans, where meta-tables are joined(Bruce)  
Enable right-hand queries by default(Bruce)

Allow reliable maximum number of backends to be set at configure time  
    (--with-maxbackends and postmaster switch (-N backends)) (Tom)  
GEQO default now 10 tables because of optimizer speedups (Tom)  
Allow NULL=Var for MS-SQL portability (Michael, Bruce)  
Modify contrib check\_primary\_key() so either "automatic" or "dependent" (Anand)  
Allow psql \d on a view show query (Ryan)  
Speedup for LIKE (Bruce)  
EcpG fixes/features, see src/interfaces/ecpg/ChangeLog file (Michael)  
JDBC fixes/features, see src/interfaces/jdbc/CHANGELOG (Peter)  
Make % operator have precedence like / (Bruce)  
Add new postgres -O option to allow system table structure changes (Bruce)  
Update contrib/pginterface/findoidjoins script (Tom)  
Major speedup in vacuum of deleted rows with indexes (Vadim)  
Allow non-SQL functions to run different versions based on arguments (Tom)  
Add -E option that shows actual queries sent by \dt and friends (Masaaki Sakaida)  
Add version number in start-up banners for psql (Masaaki Sakaida)  
New contrib/vacuumlo removes large objects not referenced (Peter)  
New initialization for table sizes so non-vacuumed tables perform better (Tom)  
Improve error messages when a connection is rejected (Tom)  
Support for arrays of char() and varchar() fields (Massimo)  
Overhaul of hash code to increase reliability and performance (Tom)  
Update to PyGreSQL 2.4 (D'Arcy)  
Changed debug options so -d4 and -d5 produce different node displays (Jan)  
New pg\_options: pretty\_plan, pretty\_parse, pretty\_rewritten (Jan)  
Better optimization statistics for system table access (Tom)  
Better handling of non-default block sizes (Massimo)  
Improve GEQO optimizer memory consumption (Tom)  
UNION now supports ORDER BY of columns not in target list (Jan)  
Major libpq++ improvements (Vince Vielhaber)  
pg\_dump now uses -z (ACL's) as default (Bruce)  
backend cache, memory speedups (Tom)  
have pg\_dump do everything in one snapshot transaction (Vadim)  
fix for large object memory leakage, fix for pg\_dumping (Tom)  
INET type now respects netmask for comparisons  
Make VACUUM ANALYZE only use a readlock (Vadim)  
Allow VIEWS on UNIONS (Jan)  
pg\_dump now can generate consistent snapshots on active databases (Vadim)

#### Source Tree Changes

-----

Improve port matching (Tom)  
Portability fixes for SunOS  
Add Windows NT backend port and enable dynamic loading (Magnus and Daniel Horak)  
New port to Cobalt Qube (Mips) running Linux (Tatsuo)  
Port to NetBSD/m68k (Mr. Mutsuki Nakajima)  
Port to NetBSD/sun3 (Mr. Mutsuki Nakajima)  
Port to NetBSD/macppc (Toshimi Aoki)  
Fix for tcl/tk configuration (Vince)  
Removed CURRENT key word for rule queries (Jan)  
NT dynamic loading now works (Daniel Horak)  
Add ARM32 support (Andrew McMurry)  
Better support for HP-UX 11 and UnixWare  
Improve file handling to be more uniform, prevent file descriptor leak (Tom)

New install commands for plpgsql(Jan)

## E.102. Release 6.4.2

**Release date:** 1998-12-20

The 6.4.1 release was improperly packaged. This also has one additional bug fix.

### E.102.1. Migration to Version 6.4.2

A dump/restore is *not* required for those running 6.4.\*.

### E.102.2. Changes

Fix for datetime constant problem on some platforms(Thomas)

## E.103. Release 6.4.1

**Release date:** 1998-12-18

This is basically a cleanup release for 6.4. We have fixed a variety of problems reported by 6.4 users.

### E.103.1. Migration to Version 6.4.1

A dump/restore is *not* required for those running 6.4.

### E.103.2. Changes

Add pg\_dump -N flag to force double quotes around identifiers. This is the default(Thomas)

Fix for NOT in where clause causing crash(Bruce)

EXPLAIN VERBOSE coredump fix(Vadim)  
 Fix shared-library problems on Linux  
 Fix test for table existence to allow mixed-case and whitespace in  
     the table name(Thomas)  
 Fix a couple of pg\_dump bugs  
 Configure matches template/.similar entries better(Tom)  
 Change builtin function names from SPI\_\* to spi\_\*  
 OR WHERE clause fix(Vadim)  
 Fixes for mixed-case table names(Billy)  
 contrib/linux/postgres.init.csh/sh fix(Thomas)  
 libpq memory overrun fix  
 SunOS fixes(Tom)  
 Change exp() behavior to generate error on underflow(Thomas)  
 pg\_dump fixes for memory leak, inheritance constraints, layout change  
 update pgaccess to 0.93  
 Fix prototype for 64-bit platforms  
 Multibyte fixes(Tatsuo)  
 New ecpg man page  
 Fix memory overruns(Tatsuo)  
 Fix for lo\_import() crash(Bruce)  
 Better search for install program(Tom)  
 Timezone fixes(Tom)  
 HP-UX fixes(Tom)  
 Use implicit type coercion for matching DEFAULT values(Thomas)  
 Add routines to help with single-byte (internal) character type(Thomas)  
 Compilation of libpq for Windows fixes(Magnus)  
 Upgrade to PyGreSQL 2.2(D'Arcy)

## E.104. Release 6.4

**Release date:** 1998-10-30

There are *many* new features and improvements in this release. Thanks to our developers and maintainers, nearly every aspect of the system has received some attention since the previous release. Here is a brief, incomplete summary:

- Views and rules are now functional thanks to extensive new code in the rewrite rules system from Jan Wieck. He also wrote a chapter on it for the *Programmer's Guide*.
- Jan also contributed a second procedural language, PL/pgSQL, to go with the original PL/pgTCL procedural language he contributed last release.
- We have optional multiple-byte character set support from Tatsuo Ishii to complement our existing locale support.

- Client/server communications has been cleaned up, with better support for asynchronous messages and interrupts thanks to Tom Lane.
- The parser will now perform automatic type coercion to match arguments to available operators and functions, and to match columns and expressions with target columns. This uses a generic mechanism which supports the type extensibility features of PostgreSQL. There is a new chapter in the *User's Guide* which covers this topic.
- Three new data types have been added. Two types, `inet` and `cidr`, support various forms of IP network, subnet, and machine addressing. There is now an 8-byte integer type available on some platforms. See the chapter on data types in the *User's Guide* for details. A fourth type, `serial`, is now supported by the parser as an amalgam of the `int4` type, a sequence, and a unique index.
- Several more SQL92-compatible syntax features have been added, including `INSERT DEFAULT VALUES`
- The automatic configuration and installation system has received some attention, and should be more robust for more platforms than it has ever been.

## E.104.1. Migration to Version 6.4

A dump/restore using `pg_dump` or `pg_dumpall` is required for those wishing to migrate data from any previous release of PostgreSQL.

## E.104.2. Changes

### Bug Fixes

-----

Fix for a tiny memory leak in `PQsetdb/PQfinish`(Bryan)  
 Remove `char2-16` data types, use `char/varchar`(Darren)  
`Pqfn` not handles a `NOTICE` message(Anders)  
 Reduced busywaiting overhead for spinlocks with many backends (dg)  
 Stuck spinlock detection (dg)  
 Fix up "ISO-style" `timespan` decoding and encoding(Thomas)  
 Fix problem with table drop after rollback of transaction(Vadim)  
 Change error message and remove non-functional update message(Vadim)  
 Fix for `COPY` array checking  
 Fix for `SELECT 1 UNION SELECT NULL`  
 Fix for buffer leaks in large object calls(Pascal)  
 Change owner from `oid` to `int4` type(Bruce)  
 Fix a bug in the oracle compatibility functions `btrim()` `ltrim()` and `rtrim()`  
 Fix for shared invalidation cache overflow(Massimo)  
 Prevent file descriptor leaks in failed `COPY`'s(Bruce)  
 Fix memory leak in `libpgtcl`'s `pg_select`(Constantin)  
 Fix problems with username/passwords over 8 characters(Tom)  
 Fix problems with handling of asynchronous `NOTIFY` in backend(Tom)  
 Fix of many bad system table entries(Tom)

### Enhancements

```

-----
Upgrade ecpg and ecpglib, see src/interfaces/ecpc/ChangeLog (Michael)
Show the index used in an EXPLAIN (Zeugswetter)
EXPLAIN invokes rule system and shows plan(s) for rewritten queries (Jan)
Multibyte awareness of many data types and functions, via configure (Tatsuo)
New configure --with-mb option (Tatsuo)
New initdb --pgencoding option (Tatsuo)
New createdb -E multibyte option (Tatsuo)
Select version(); now returns PostgreSQL version (Jeroen)
libpq now allows asynchronous clients (Tom)
Allow cancel from client of backend query (Tom)
psql now cancels query with Control-C (Tom)
libpq users need not issue dummy queries to get NOTIFY messages (Tom)
NOTIFY now sends sender's PID, so you can tell whether it was your own (Tom)
PGresult struct now includes associated error message, if any (Tom)
Define "tz_hour" and "tz_minute" arguments to date_part() (Thomas)
Add routines to convert between varchar and bpchar (Thomas)
Add routines to allow sizing of varchar and bpchar into target columns (Thomas)
Add bit flags to support timezonehour and minute in data retrieval (Thomas)
Allow more variations on valid floating point numbers (e.g. ".1", "1e6") (Thomas)
Fixes for unary minus parsing with leading spaces (Thomas)
Implement TIMEZONE_HOUR, TIMEZONE_MINUTE per SQL92 specs (Thomas)
Check for and properly ignore FOREIGN KEY column constraints (Thomas)
Define USER as synonym for CURRENT_USER per SQL92 specs (Thomas)
Enable HAVING clause but no fixes elsewhere yet.
Make "char" type a synonym for "char(1)" (actually implemented as bpchar) (Thomas)
Save string type if specified for DEFAULT clause handling (Thomas)
Coerce operations involving different data types (Thomas)
Allow some index use for columns of different types (Thomas)
Add capabilities for automatic type conversion (Thomas)
Cleanups for large objects, so file is truncated on open (Peter)
Readline cleanups (Tom)
Allow psql \f \ to make spaces as delimiter (Bruce)
Pass pg_attribute.atttypmod to the frontend for column field lengths (Tom, Bruce)
Msql compatibility library in /contrib (Aldrin)
Remove the requirement that ORDER/GROUP BY clause identifiers be
included in the target list (David)
Convert columns to match columns in UNION clauses (Thomas)
Remove fork()/exec() and only do fork() (Bruce)
Jdbc cleanups (Peter)
Show backend status on ps command line (only works on some platforms) (Bruce)
Pg_hba.conf now has a sameuser option in the database field
Make lo_unlink take oid param, not int4
New DISABLE_COMPLEX_MACRO for compilers that cannot handle our macros (Bruce)
Libpgtcl now handles NOTIFY as a Tcl event, need not send dummy queries (Tom)
libpgtcl cleanups (Tom)
Add -error option to libpgtcl's pg_result command (Tom)
New locale patch, see docs/README/locale (Oleg)
Fix for pg_dump so CONSTRAINT and CHECK syntax is correct (ccb)
New contrib/lo code for large object orphan removal (Peter)
New psql command "SET CLIENT_ENCODING TO 'encoding'" for multibytes
feature, see /doc/README.mb (Tatsuo)
contrib/noupdate code to revoke update permission on a column

```

libpq can now be compiled on Windows (Magnus)  
Add PQsetdbLogin() in libpq  
New 8-byte integer type, checked by configure for OS support (Thomas)  
Better support for quoted table/column names (Thomas)  
Surround table and column names with double-quotes in pg\_dump (Thomas)  
PQreset() now works with passwords (Tom)  
Handle case of GROUP BY target list column number out of range (David)  
Allow UNION in subselects  
Add auto-size to screen to \d? commands (Bruce)  
Use UNION to show all \d? results in one query (Bruce)  
Add \d? field search feature (Bruce)  
Pg\_dump issues fewer \connect requests (Tom)  
Make pg\_dump -z flag work better, document it in manual page (Tom)  
Add HAVING clause with full support for subselects and unions (Stephan)  
Full text indexing routines in contrib/fulltextindex (Maarten)  
Transaction ids now stored in shared memory (Vadim)  
New PGCLIENTENCODING when issuing COPY command (Tatsuo)  
Support for SQL92 syntax "SET NAMES" (Tatsuo)  
Support for LATIN2-5 (Tatsuo)  
Add UNICODE regression test case (Tatsuo)  
Lock manager cleanup, new locking modes for LLL (Vadim)  
Allow index use with OR clauses (Bruce)  
Allows "SELECT NULL ORDER BY 1;"  
Explain VERBOSE prints the plan, and now pretty-prints the plan to the postmaster log file (Bruce)  
Add indexes display to \d command (Bruce)  
Allow GROUP BY on functions (David)  
New pg\_class.relkind for large objects (Bruce)  
New way to send libpq NOTICE messages to a different location (Tom)  
New \w write command to psql (Bruce)  
New /contrib/findoidjoins scans oid columns to find join relationships (Bruce)  
Allow binary-compatible indexes to be considered when checking for valid  
Indexes for restriction clauses containing a constant (Thomas)  
New ISBN/ISSN code in /contrib/isbn\_issn  
Allow NOT LIKE, IN, NOT IN, BETWEEN, and NOT BETWEEN constraint (Thomas)  
New rewrite system fixes many problems with rules and views (Jan)

- \* Rules on relations work
- \* Event qualifications on insert/update/delete work
- \* New OLD variable to reference CURRENT, CURRENT will be remove in future
- \* Update rules can reference NEW and OLD in rule qualifications/actions
- \* Insert/update/delete rules on views work
- \* Multiple rule actions are now supported, surrounded by parentheses
- \* Regular users can create views/rules on tables they have RULE permits
- \* Rules and views inherit the privileges of the creator
- \* No rules at the column level
- \* No UPDATE NEW/OLD rules
- \* New pg\_tables, pg\_indexes, pg\_rules and pg\_views system views
- \* Only a single action on SELECT rules
- \* Total rewrite overhaul, perhaps for 6.5
- \* handle subselects
- \* handle aggregates on views
- \* handle insert into select from view works

System indexes are now multikey (Bruce)

Oidint2, oidint4, and oidname types are removed(Bruce)  
Use system cache for more system table lookups(Bruce)  
New backend programming language PL/pgSQL in backend/pl(Jan)  
New SERIAL data type, auto-creates sequence/index(Thomas)  
Enable assert checking without a recompile(Massimo)  
User lock enhancements(Massimo)  
New setval() command to set sequence value(Massimo)  
Auto-remove unix socket file on start-up if no postmaster running(Massimo)  
Conditional trace package(Massimo)  
New UNLISTEN command(Massimo)  
psql and libpq now compile under Windows using win32.mak(Magnus)  
Lo\_read no longer stores trailing NULL(Bruce)  
Identifiers are now truncated to 31 characters internally(Bruce)  
Createuser options now available on the command line  
Code for 64-bit integer supported added, configure tested, int8 type(Thomas)  
Prevent file descriptor leak from failed COPY(Bruce)  
New pg\_upgrade command(Bruce)  
Updated /contrib directories(Massimo)  
New CREATE TABLE DEFAULT VALUES statement available(Thomas)  
New INSERT INTO TABLE DEFAULT VALUES statement available(Thomas)  
New DECLARE and FETCH feature(Thomas)  
libpq's internal structures now not exported(Tom)  
Allow up to 8 key indexes(Bruce)  
Remove ARCHIVE key word, that is no longer used(Thomas)  
pg\_dump -n flag to suppress quotes around identifiers  
disable system columns for views(Jan)  
new INET and CIDR types for network addresses(TomH, Paul)  
no more double quotes in psql output  
pg\_dump now dumps views(Terry)  
new SET QUERY\_LIMIT(Tatsuo, Jan)

#### Source Tree Changes

-----  
/contrib cleanup(Jun)  
Inline some small functions called for every row(Bruce)  
Alpha/linux fixes  
HP-UX cleanups(Tom)  
Multibyte regression tests(Soonmyung.)  
Remove --disabled options from configure  
Define PGDOC to use POSTGRES DIR by default  
Make regression optional  
Remove extra braces code to pgindent(Bruce)  
Add bsdi shared library support(Bruce)  
New --without-CXX support configure option(Brook)  
New FAQ\_CVS  
Update backend flowchart in tools/backend(Bruce)  
Change atttypmod from int16 to int32(Bruce, Tom)  
Getusage() fix for platforms that do not have it(Tom)  
Add PQconnectdb, PGUSER, PGPASSWORD to libpq man page  
NS32K platform fixes(Phil Nelson, John Buller)  
SCO 7/UnixWare 2.x fixes(Billy, others)  
Sparc/Solaris 2.5 fixes(Ryan)  
Pgbuiltin.3 is obsolete, move to doc files(Thomas)

Even more documentation(Thomas)  
Nextstep support(Jacek)  
Aix support(David)  
pginterface manual page(Bruce)  
shared libraries all have version numbers  
merged all OS-specific shared library defines into one file  
smarter TCL/TK configuration checking(Billy)  
smarter perl configuration(Brook)  
configure uses supplied install-sh if no install script found(Tom)  
new Makefile.shlib for shared library configuration(Tom)

## E.105. Release 6.3.2

**Release date:** 1998-04-07

This is a bug-fix release for 6.3.x. Refer to the release notes for version 6.3 for a more complete summary of new features.

Summary:

- Repairs automatic configuration support for some platforms, including Linux, from breakage inadvertently introduced in version 6.3.1.
- Correctly handles function calls on the left side of BETWEEN and LIKE clauses.

A dump/restore is NOT required for those running 6.3 or 6.3.1. A `make distclean`, `make`, and `make install` is all that is required. This last step should be performed while the postmaster is not running. You should re-link any custom applications that use PostgreSQL libraries.

For upgrades from pre-6.3 installations, refer to the installation and migration instructions for version 6.3.

### E.105.1. Changes

Configure detection improvements for tcl/tk(Brook Milligan, Alvin)  
Manual page improvements(Bruce)  
BETWEEN and LIKE fix(Thomas)  
fix for psql \connect used by pg\_dump(Oliver Elphick)  
New odbc driver  
pgaccess, version 0.86  
qsort removed, now uses libc version, cleanups(Jeroen)  
fix for buffer over-runs detected(Maurice Gittens)  
fix for buffer overrun in libpgtcl(Randy Kunkee)  
fix for UNION with DISTINCT or ORDER BY(Bruce)

gettimeofday configure check (Doug Winterburn)  
Fix "indexes not used" bug (Vadim)  
docs additions (Thomas)  
Fix for backend memory leak (Bruce)  
libreadline cleanup (Erwan MAS)  
Remove DISTDIR (Bruce)  
Makefile dependency cleanup (Jeroen van Vianen)  
ASSERT fixes (Bruce)

## E.106. Release 6.3.1

**Release date:** 1998-03-23

Summary:

- Additional support for multibyte character sets.
- Repair byte ordering for mixed-endian clients and servers.
- Minor updates to allowed SQL syntax.
- Improvements to the configuration autodetection for installation.

A dump/restore is NOT required for those running 6.3. A `make distclean`, `make`, and `make install` is all that is required. This last step should be performed while the postmaster is not running. You should re-link any custom applications that use PostgreSQL libraries.

For upgrades from pre-6.3 installations, refer to the installation and migration instructions for version 6.3.

### E.106.1. Changes

ecpg cleanup/fixes, now version 1.1 (Michael Meskes)  
pg\_user cleanup (Bruce)  
large object fix for `pg_dump` and `tcsh` (alvin)  
LIKE fix for multiple adjacent underscores  
fix for redefining builtin functions (Thomas)  
ultrix4 cleanup  
upgrade to `pg_access` 0.83  
updated CLUSTER manual page  
multibyte character set support, see `doc/README.mb` (Tatsuo)  
`configure --with-pgport` fix  
`pg_ident` fix

big-endian fix for backend communications (Kataoka)  
 SUBSTR() and substring() fix (Jan)  
 several jdbc fixes (Peter)  
 libpgtcl improvements, see libpgtcl/README (Randy Kunkee)  
 Fix for "Datasize = 0" error (Vadim)  
 Prevent \do from wrapping (Bruce)  
 Remove duplicate Russian character set entries  
 Sunos4 cleanup  
 Allow optional TABLE key word in LOCK and SELECT INTO (Thomas)  
 CREATE SEQUENCE options to allow a negative integer (Thomas)  
 Add "PASSWORD" as an allowed column identifier (Thomas)  
 Add checks for UNION target fields (Bruce)  
 Fix Alpha port (Dwayne Bailey)  
 Fix for text arrays containing quotes (Doug Gibson)  
 Solaris compile fix (Albert Chin-A-Young)  
 Better identify tcl and tk libs and includes (Bruce)

## E.107. Release 6.3

**Release date:** 1998-03-01

There are *many* new features and improvements in this release. Here is a brief, incomplete summary:

- Many new SQL features, including full SQL92 subselect capability (everything is here but target-list subselects).
- Support for client-side environment variables to specify time zone and date style.
- Socket interface for client/server connection. This is the default now so you might need to start postmaster with the `-i` flag.
- Better password authorization mechanisms. Default table privileges have changed.
- Old-style *time travel* has been removed. Performance has been improved.

**Note:** Bruce Momjian wrote the following notes to introduce the new release.

There are some general 6.3 issues that I want to mention. These are only the big items that cannot be described in one sentence. A review of the detailed changes list is still needed.

First, we now have subselects. Now that we have them, I would like to mention that without subselects, SQL is a very limited language. Subselects are a major feature, and you should review your code for

places where subselects provide a better solution for your queries. I think you will find that there are more uses for subselects than you might think. Vadim has put us on the big SQL map with subselects, and fully functional ones too. The only thing you cannot do with subselects is to use them in the target list.

Second, 6.3 uses Unix domain sockets rather than TCP/IP by default. To enable connections from other machines, you have to use the new `postmaster -i` option, and of course edit `pg_hba.conf`. Also, for this reason, the format of `pg_hba.conf` has changed.

Third, `char()` fields will now allow faster access than `varchar()` or `text`. Specifically, the `text` and `varchar()` have a penalty for access to any columns after the first column of this type. `char()` used to also have this access penalty, but it no longer does. This might suggest that you redesign some of your tables, especially if you have short character columns that you have defined as `varchar()` or `text`. This and other changes make 6.3 even faster than earlier releases.

We now have passwords definable independent of any Unix file. There are new SQL `USER` commands. See the *Administrator's Guide* for more information. There is a new table, `pg_shadow`, which is used to store user information and user passwords, and it by default only `SELECT`-able by the postgres super-user. `pg_user` is now a view of `pg_shadow`, and is `SELECT`-able by `PUBLIC`. You should keep using `pg_user` in your application without changes.

User-created tables now no longer have `SELECT` privilege to `PUBLIC` by default. This was done because the ANSI standard requires it. You can of course `GRANT` any privileges you want after the table is created. System tables continue to be `SELECT`-able by `PUBLIC`.

We also have real deadlock detection code. No more sixty-second timeouts. And the new locking code implements a FIFO better, so there should be less resource starvation during heavy use.

Many complaints have been made about inadequate documentation in previous releases. Thomas has put much effort into many new manuals for this release. Check out the `doc/` directory.

For performance reasons, time travel is gone, but can be implemented using triggers (see `pgsql/contrib/spi/README`). Please check out the new `\d` command for types, operators, etc. Also, views have their own privileges now, not based on the underlying tables, so privileges on them have to be set separately. Check `/pgsql/interfaces` for some new ways to talk to PostgreSQL.

This is the first release that really required an explanation for existing users. In many ways, this was necessary because the new release removes many limitations, and the work-arounds people were using are no longer needed.

## E.107.1. Migration to Version 6.3

A dump/restore using `pg_dump` or `pg_dumpall` is required for those wishing to migrate data from any previous release of PostgreSQL.

## E.107.2. Changes

### Bug Fixes

-----

Fix binary cursors broken by MOVE implementation (Vadim)

Fix for tcl library crash (Jan)

Fix for array handling, from Gerhard Hintermayer

Fix acl error, and remove duplicate pgtrace(Bruce)  
 Fix psql \e for empty file(Bruce)  
 Fix for textcat on varchar() fields(Bruce)  
 Fix for DBT Sendproc (Zeugswetter Andres)  
 Fix vacuum analyze syntax problem(Bruce)  
 Fix for international identifiers(Tatsuo)  
 Fix aggregates on inherited tables(Bruce)  
 Fix substr() for out-of-bounds data  
 Fix for select 1=1 or 2=2, select 1=1 and 2=2, and select sum(2+2)(Bruce)  
 Fix notty output to show status result. -q option still turns it off(Bruce)  
 Fix for count(\*), aggs with views and multiple tables and sum(3)(Bruce)  
 Fix cluster(Bruce)  
 Fix for PQtrace start/stop several times(Bruce)  
 Fix a variety of locking problems like newer lock waiters getting  
     lock before older waiters, and having readlock people not share  
     locks if a writer is waiting for a lock, and waiting writers not  
     getting priority over waiting readers(Bruce)  
 Fix crashes in psql when executing queries from external files(James)  
 Fix problem with multiple order by columns, with the first one having  
     NULL values(Jeroen)  
 Use correct hash table support functions for float8 and int4(Thomas)  
 Re-enable JOIN= option in CREATE OPERATOR statement (Thomas)  
 Change precedence for boolean operators to match expected behavior(Thomas)  
 Generate elog(ERROR) on over-large integer(Bruce)  
 Allow multiple-argument functions in constraint clauses(Thomas)  
 Check boolean input literals for 'true','false','yes','no','1','0'  
     and throw elog(ERROR) if unrecognized(Thomas)  
 Major large objects fix  
 Fix for GROUP BY showing duplicates(Vadim)  
 Fix for index scans in MergeJoin(Vadim)

#### Enhancements

-----

Subselects with EXISTS, IN, ALL, ANY key words (Vadim, Bruce, Thomas)  
 New User Manual(Thomas, others)  
 Speedup by inlining some frequently-called functions  
 Real deadlock detection, no more timeouts(Bruce)  
 Add SQL92 "constants" CURRENT\_DATE, CURRENT\_TIME, CURRENT\_TIMESTAMP,  
     CURRENT\_USER(Thomas)  
 Modify constraint syntax to be SQL92-compliant(Thomas)  
 Implement SQL92 PRIMARY KEY and UNIQUE clauses using indexes(Thomas)  
 Recognize SQL92 syntax for FOREIGN KEY. Throw elog notice(Thomas)  
 Allow NOT NULL UNIQUE constraint clause (each allowed separately before)(Thomas)  
 Allow PostgreSQL-style casting ("::") of non-constants(Thomas)  
 Add support for SQL3 TRUE and FALSE boolean constants(Thomas)  
 Support SQL92 syntax for IS TRUE/IS FALSE/IS NOT TRUE/IS NOT FALSE(Thomas)  
 Allow shorter strings for boolean literals (e.g. "t", "tr", "tru")(Thomas)  
 Allow SQL92 delimited identifiers(Thomas)  
 Implement SQL92 binary and hexadecimal string decoding (b'10' and x'1F')(Thomas)  
 Support SQL92 syntax for type coercion of literal strings  
     (e.g. "DATETIME 'now'")(Thomas)  
 Add conversions for int2, int4, and OID types to and from text(Thomas)  
 Use shared lock when building indexes(Vadim)

Free memory allocated for an user query inside transaction block after  
    this query is done, was turned off in <= 6.2.1 (Vadim)

New SQL statement CREATE PROCEDURAL LANGUAGE (Jan)

New PostgreSQL Procedural Language (PL) backend interface (Jan)

Rename pg\_dump -H option to -h (Bruce)

Add Java support for passwords, European dates (Peter)

Use indexes for LIKE and ~, !~ operations (Bruce)

Add hash functions for datetime and timespan (Thomas)

Time Travel removed (Vadim, Bruce)

Add paging for \d and \z, and fix \i (Bruce)

Add Unix domain socket support to backend and to frontend library (Goran)

Implement CREATE DATABASE/WITH LOCATION and initlocation utility (Thomas)

Allow more SQL92 and/or PostgreSQL reserved words as column identifiers (Thomas)

Augment support for SQL92 SET TIME ZONE... (Thomas)

SET/SHOW/RESET TIME ZONE uses TZ backend environment variable (Thomas)

Implement SET keyword = DEFAULT and SET TIME ZONE DEFAULT (Thomas)

Enable SET TIME ZONE using TZ environment variable (Thomas)

Add PGDATESTYLE environment variable to frontend and backend initialization (Thomas)

Add PGTZ, PGCSOHEAP, PGCSOINDEX, PGRPLANS, PGGEQO  
    frontend library initialization environment variables (Thomas)

Regression tests time zone automatically set with "setenv PGTZ PST8PDT" (Thomas)

Add pg\_description table for info on tables, columns, operators, types, and  
    aggregates (Bruce)

Increase 16 char limit on system table/index names to 32 characters (Bruce)

Rename system indexes (Bruce)

Add 'GERMAN' option to SET DATESTYLE (Thomas)

Define an "ISO-style" timespan output format with "hh:mm:ss" fields (Thomas)

Allow fractional values for delta times (e.g. '2.5 days') (Thomas)

Validate numeric input more carefully for delta times (Thomas)

Implement day of year as possible input to date\_part() (Thomas)

Define timespan\_finite() and text\_timespan() functions (Thomas)

Remove archive stuff (Bruce)

Allow for a pg\_password authentication database that is separate from  
    the system password file (Todd)

Dump ACLs, GRANT, REVOKE privileges (Matt)

Define text, varchar, and bpchar string length functions (Thomas)

Fix Query handling for inheritance, and cost computations (Bruce)

Implement CREATE TABLE/AS SELECT (alternative to SELECT/INTO) (Thomas)

Allow NOT, IS NULL, IS NOT NULL in constraints (Thomas)

Implement UNIONS for SELECT (Bruce)

Add UNION, GROUP, DISTINCT to INSERT (Bruce)

varchar() stores only necessary bytes on disk (Bruce)

Fix for BLOBs (Peter)

Mega-Patch for JDBC...see README\_6.3 for list of changes (Peter)

Remove unused "option" from PQconnectdb()

New LOCK command and lock manual page describing deadlocks (Bruce)

Add new psql \da, \dd, \df, \do, \dS, and \dT commands (Bruce)

Enhance psql \z to show sequences (Bruce)

Show NOT NULL and DEFAULT in psql \d table (Bruce)

New psql .psqlrc file start-up (Andrew)

Modify sample start-up script in contrib/linux to show syslog (Thomas)

New types for IP and MAC addresses in contrib/ip\_and\_mac (TomH)

Unix system time conversions with date/time types in contrib/unixdate (Thomas)

Update of contrib stuff(Massimo)  
Add Unix socket support to DBD::Pg(Goran)  
New python interface (PyGreSQL 2.0)(D'Arcy)  
New frontend/backend protocol has a version number, network byte order(Phil)  
Security features in pg\_hba.conf enhanced and documented, many cleanups(Phil)  
CHAR() now faster access than VARCHAR() or TEXT  
ecpg embedded SQL preprocessor  
Reduce system column overhead(Vadmin)  
Remove pg\_time table(Vadim)  
Add pg\_type attribute to identify types that need length (bpchar, varchar)  
Add report of offending line when COPY command fails  
Allow VIEW privileges to be set separately from the underlying tables.  
    For security, use GRANT/REVOKE on views as appropriate(Jan)  
Tables now have no default GRANT SELECT TO PUBLIC. You must  
    explicitly grant such privileges.  
Clean up tutorial examples(Darren)

#### Source Tree Changes

-----  
Add new html development tools, and flow chart in /tools/backend  
Fix for SCO compiles  
Stratus computer port Robert Gillies  
Added support for shlib for BSD44\_derived & i386\_solaris  
Make configure more automated(Brook)  
Add script to check regression test results  
Break parser functions into smaller files, group together(Bruce)  
Rename heap\_create to heap\_create\_and\_catalog, rename heap\_creatr  
    to heap\_create() (Bruce)  
Sparc/Linux patch for locking(TomS)  
Remove PORTNAME and reorganize port-specific stuff(Marc)  
Add optimizer README file(Bruce)  
Remove some recursion in optimizer and clean up some code there(Bruce)  
Fix for NetBSD locking(Henry)  
Fix for libptcl make(Tatsuo)  
AIX patch(Darren)  
Change IS TRUE, IS FALSE, ... to expressions using "=" rather than  
    function calls to isttrue() or isfalse() to allow optimization(Thomas)  
Various fixes NetBSD/Sparc related(TomH)  
Alpha linux locking(Travis,Ryan)  
Change elog(WARN) to elog(ERROR) (Bruce)  
FAQ for FreeBSD(Marc)  
Bring in the PostODBC source tree as part of our standard distribution(Marc)  
A minor patch for HP/UX 10 vs 9(Stan)  
New pg\_attribute.atttypmod for type-specific info like varchar length(Bruce)  
UnixWare patches(Billy)  
New i386 'lock' for spinlock asm(Billy)  
Support for multiplexed backends is removed  
Start an OpenBSD port  
Start an AUX port  
Start a Cygnus port  
Add string functions to regression suite(Thomas)  
Expand a few function names formerly truncated to 16 characters(Thomas)  
Remove un-needed malloc() calls and replace with pallocc() (Bruce)

## E.108. Release 6.2.1

**Release date:** 1997-10-17

6.2.1 is a bug-fix and usability release on 6.2.

Summary:

- Allow strings to span lines, per SQL92.
- Include example trigger function for inserting user names on table updates.

This is a minor bug-fix release on 6.2. For upgrades from pre-6.2 systems, a full dump/reload is required. Refer to the 6.2 release notes for instructions.

### E.108.1. Migration from version 6.2 to version 6.2.1

This is a minor bug-fix release. A dump/reload is not required from version 6.2, but is required from any release prior to 6.2.

In upgrading from version 6.2, if you choose to dump/reload you will find that `avg(money)` is now calculated correctly. All other bug fixes take effect upon updating the executables.

Another way to avoid dump/reload is to use the following SQL command from `psql` to update the existing system table:

```
update pg_aggregate set aggfinalfn = 'cash_div_flt8'
where aggrname = 'avg' and aggbasetype = 790;
```

This will need to be done to every existing database, including `template1`.

### E.108.2. Changes

```
Allow TIME and TYPE column names(Thomas)
Allow larger range of true/false as boolean values(Thomas)
Support output of "now" and "current"(Thomas)
Handle DEFAULT with INSERT of NULL properly(Vadim)
Fix for relation reference counts problem in buffer manager(Vadim)
Allow strings to span lines, like ANSI(Thomas)
Fix for backward cursor with ORDER BY(Vadim)
Fix avg(cash) computation(Thomas)
```

Fix for specifying a column twice in ORDER/GROUP BY (Vadim)  
Documented new libpq function to return affected rows, PQcmdTuples (Bruce)  
Trigger function for inserting user names for INSERT/UPDATE (Brook Milligan)

## E.109. Release 6.2

**Release date:** 1997-10-02

A dump/restore is required for those wishing to migrate data from previous releases of PostgreSQL.

### E.109.1. Migration from version 6.1 to version 6.2

This migration requires a complete dump of the 6.1 database and a restore of the database in 6.2.

Note that the `pg_dump` and `pg_dumpall` utility from 6.2 should be used to dump the 6.1 database.

### E.109.2. Migration from version 1.x to version 6.2

Those migrating from earlier 1.\* releases should first upgrade to 1.09 because the COPY output format was improved from the 1.02 release.

### E.109.3. Changes

#### Bug Fixes

-----  
Fix problems with `pg_dump` for inheritance, sequences, archive tables (Bruce)  
Fix compile errors on overflow due to shifts, unsigned, and bad prototypes  
from Solaris (Diab Jerius)  
Fix bugs in geometric line arithmetic (bad intersection calculations) (Thomas)  
Check for geometric intersections at endpoints to avoid rounding ugliness (Thomas)  
Catch non-functional delete attempts (Vadim)  
Change time function names to be more consistent (Michael Reifenberg)  
Check for zero divides (Michael Reifenberg)  
Fix very old bug which made rows changed/inserted by a command  
visible to the command itself (so we had multiple update of  
updated rows, etc.) (Vadim)  
Fix for SELECT null, 'fail' FROM pg\_am (Patrick)  
SELECT NULL as EMPTY\_FIELD now allowed (Patrick)  
Remove un-needed signal stuff from contrib/pginterface  
Fix OR (where x != 1 or x isnull didn't return rows with x NULL) (Vadim)

Fix time\_cmp function (Vadim)  
Fix handling of functions with non-attribute first argument in  
WHERE clauses (Vadim)  
Fix GROUP BY when order of entries is different from order  
in target list (Vadim)  
Fix pg\_dump for aggregates without sfunc1 (Vadim)

Enhancements  
-----

Default genetic optimizer GEQO parameter is now 8 (Bruce)  
Allow use parameters in target list having aggregates in functions (Vadim)  
Added JDBC driver as an interface (Adrian & Peter)  
pg\_password utility  
Return number of rows inserted/affected by INSERT/UPDATE/DELETE etc. (Vadim)  
Triggers implemented with CREATE TRIGGER (SQL3) (Vadim)  
SPI (Server Programming Interface) allows execution of queries inside  
C-functions (Vadim)  
NOT NULL implemented (SQL92) (Robson Paniago de Miranda)  
Include reserved words for string handling, outer joins, and unions (Thomas)  
Implement extended comments ("/ \* ... \*/") using exclusive states (Thomas)  
Add "/\*" single-line comments (Bruce)  
Remove some restrictions on characters in operator names (Thomas)  
DEFAULT and CONSTRAINT for tables implemented (SQL92) (Vadim & Thomas)  
Add text concatenation operator and function (SQL92) (Thomas)  
Support WITH TIME ZONE syntax (SQL92) (Thomas)  
Support INTERVAL unit TO unit syntax (SQL92) (Thomas)  
Define types DOUBLE PRECISION, INTERVAL, CHARACTER,  
and CHARACTER VARYING (SQL92) (Thomas)  
Define type FLOAT(p) and rudimentary DECIMAL(p,s), NUMERIC(p,s) (SQL92) (Thomas)  
Define EXTRACT(), POSITION(), SUBSTRING(), and TRIM() (SQL92) (Thomas)  
Define CURRENT\_DATE, CURRENT\_TIME, CURRENT\_TIMESTAMP (SQL92) (Thomas)  
Add syntax and warnings for UNION, HAVING, INNER and OUTER JOIN (SQL92) (Thomas)  
Add more reserved words, mostly for SQL92 compliance (Thomas)  
Allow hh:mm:ss time entry for timespan/reftime types (Thomas)  
Add center() routines for lseg, path, polygon (Thomas)  
Add distance() routines for circle-polygon, polygon-polygon (Thomas)  
Check explicitly for points and polygons contained within polygons  
using an axis-crossing algorithm (Thomas)  
Add routine to convert circle-box (Thomas)  
Merge conflicting operators for different geometric data types (Thomas)  
Replace distance operator "<==>" with "<->" (Thomas)  
Replace "above" operator "!^" with ">^" and "below" operator "!!" with "<^" (Thomas)  
Add routines for text trimming on both ends, substring, and string position (Thomas)  
Added conversion routines circle(box) and poly(circle) (Thomas)  
Allow internal sorts to be stored in memory rather than in files (Bruce & Vadim)  
Allow functions and operators on internally-identical types to succeed (Bruce)  
Speed up backend start-up after profiling analysis (Bruce)  
Inline frequently called functions for performance (Bruce)  
Reduce open() calls (Bruce)  
psql: Add PAGER for \h and \?, \C fix  
Fix for psql pager when no tty (Bruce)  
New entab utility (Bruce)  
General trigger functions for referential integrity (Vadim)

General trigger functions for time travel (Vadim)  
General trigger functions for AUTOINCREMENT/IDENTITY feature (Vadim)  
MOVE implementation (Vadim)

Source Tree Changes

-----  
HP-UX 10 patches (Vladimir Turin)  
Added SCO support, (Daniel Harris)  
MkLinux patches (Tatsuo Ishii)  
Change geometric box terminology from "length" to "width"(Thomas)  
Deprecate temporary unstored slope fields in geometric code(Thomas)  
Remove restart instructions from INSTALL(Bruce)  
Look in /usr/ucb first for install(Bruce)  
Fix c++ copy example code(Thomas)  
Add -o to psql manual page(Bruce)  
Prevent relname unallocated string length from being copied into database(Bruce)  
Cleanup for NAMEDATALEN use(Bruce)  
Fix pg\_proc names over 15 chars in output(Bruce)  
Add strNcpy() function(Bruce)  
remove some (void) casts that are unnecessary(Bruce)  
new interfaces directory(Marc)  
Replace fopen() calls with calls to fd.c functions(Bruce)  
Make functions static where possible(Bruce)  
enclose unused functions in #ifdef NOT\_USED(Bruce)  
Remove call to difftime() in timestamp support to fix SunOS(Bruce & Thomas)  
Changes for Digital Unix  
Portability fix for pg\_dumpall(Bruce)  
Rename pg\_attribute.attnvals to attdispersion(Bruce)  
"intro/unix" manual page now "pgintro"(Bruce)  
"built-in" manual page now "pgbuiltin"(Bruce)  
"drop" manual page now "drop\_table"(Bruce)  
Add "create\_trigger", "drop\_trigger" manual pages(Thomas)  
Add constraints regression test(Vadim & Thomas)  
Add comments syntax regression test(Thomas)  
Add PGINDENT and support program(Bruce)  
Massive commit to run PGINDENT on all \*.c and \*.h files(Bruce)  
Files moved to /src/tools directory(Bruce)  
SPI and Trigger programming guides (Vadim & D'Arcy)

## **E.110. Release 6.1.1**

**Release date:** 1997-07-22

### E.110.1. Migration from version 6.1 to version 6.1.1

This is a minor bug-fix release. A dump/reload is not required from version 6.1, but is required from any release prior to 6.1. Refer to the release notes for 6.1 for more details.

### E.110.2. Changes

```
fix for SET with options (Thomas)
allow pg_dump/pg_dumpall to preserve ownership of all tables/objects (Bruce)
new psql \connect option allows changing usernames without changing databases
fix for initdb --debug option (Yoshihiko Ichikawa)
lextest cleanup (Bruce)
hash fixes (Vadim)
fix date/time month boundary arithmetic (Thomas)
fix timezone daylight handling for some ports (Thomas, Bruce, Tatsuo)
timestamp overhauled to use standard functions (Thomas)
other code cleanup in date/time routines (Thomas)
psql's \d now case-insensitive (Bruce)
psql's backslash commands can now have trailing semicolon (Bruce)
fix memory leak in psql when using \g (Bruce)
major fix for endian handling of communication to server (Thomas, Tatsuo)
Fix for Solaris assembler and include files (Yoshihiko Ichikawa)
allow underscores in usernames (Bruce)
pg_dumpall now returns proper status, portability fix (Bruce)
```

## E.111. Release 6.1

**Release date:** 1997-06-08

The regression tests have been adapted and extensively modified for the 6.1 release of PostgreSQL.

Three new data types (`datetime`, `timespan`, and `circle`) have been added to the native set of PostgreSQL types. Points, boxes, paths, and polygons have had their output formats made consistent across the data types. The polygon output in `misc.out` has only been spot-checked for correctness relative to the original regression output.

PostgreSQL 6.1 introduces a new, alternate optimizer which uses *genetic* algorithms. These algorithms introduce a random behavior in the ordering of query results when the query contains multiple qualifiers or multiple tables (giving the optimizer a choice on order of evaluation). Several regression tests have been modified to explicitly order the results, and hence are insensitive to optimizer choices. A few regression tests are for data types which are inherently unordered (e.g. points and time intervals) and tests involving those types are explicitly bracketed with `set geqo to 'off'` and `reset geqo`.

The interpretation of array specifiers (the curly braces around atomic values) appears to have changed sometime after the original regression tests were generated. The current `./expected/*.out` files reflect this new interpretation, which might not be correct!

The float8 regression test fails on at least some platforms. This is due to differences in implementations of `pow()` and `exp()` and the signaling mechanisms used for overflow and underflow conditions.

The “random” results in the random test should cause the “random” test to be “failed”, since the regression tests are evaluated using a simple diff. However, “random” does not seem to produce random results on my test machine (Linux/gcc/i686).

## E.111.1. Migration to Version 6.1

This migration requires a complete dump of the 6.0 database and a restore of the database in 6.1.

Those migrating from earlier 1.\* releases should first upgrade to 1.09 because the COPY output format was improved from the 1.02 release.

## E.111.2. Changes

### Bug Fixes

-----

```
packet length checking in library routines
lock manager priority patch
check for under/over flow of float8(Bruce)
multitable join fix(Vadim)
SIGPIPE crash fix(Darren)
large object fixes(Sven)
allow btree indexes to handle NULLs(Vadim)
timezone fixes(D'Arcy)
select SUM(x) can return NULL on no rows(Thomas)
internal optimizer, executor bug fixes(Vadim)
fix problem where inner loop in < or <= has no rows(Vadim)
prevent re-commuting join index clauses(Vadim)
fix join clauses for multiple tables(Vadim)
fix hash, hashjoin for arrays(Vadim)
fix btree for abstime type(Vadim)
large object fixes(Raymond)
fix buffer leak in hash indexes (Vadim)
fix rtree for use in inner scan (Vadim)
fix gist for use in inner scan, cleanups (Vadim, Andrea)
avoid unnecessary local buffers allocation (Vadim, Massimo)
fix local buffers leak in transaction aborts (Vadim)
fix file manager memory leaks, cleanups (Vadim, Massimo)
fix storage manager memory leaks (Vadim)
fix btree duplicates handling (Vadim)
fix deleted rows reincarnation caused by vacuum (Vadim)
fix SELECT varchar()/char() INTO TABLE made zero-length fields(Bruce)
many psql, pg_dump, and libpq memory leaks fixed using Purify (Igor)
```

## Enhancements

-----

attribute optimization statistics(Bruce)  
 much faster new btree bulk load code(Paul)  
 BTREE UNIQUE added to bulk load code(Vadim)  
 new lock debug code(Massimo)  
 massive changes to libpg++(Leo)  
 new GEQO optimizer speeds table multitable optimization(Martin)  
 new WARN message for non-unique insert into unique key(Marc)  
 update x=-3, no spaces, now valid(Bruce)  
 remove case-sensitive identifier handling(Bruce,Thomas,Dan)  
 debug backend now pretty-prints tree(Darren)  
 new Oracle character functions(Edmund)  
 new plaintext password functions(Dan)  
 no such class or insufficient privilege changed to distinct messages(Dan)  
 new ANSI timestamp function(Dan)  
 new ANSI Time and Date types (Thomas)  
 move large chunks of data in backend(Martin)  
 multicolumn btree indexes(Vadim)  
 new SET var TO value command(Martin)  
 update transaction status on reads(Dan)  
 new locale settings for character types(Oleg)  
 new SEQUENCE serial number generator(Vadim)  
 GROUP BY function now possible(Vadim)  
 re-organize regression test(Thomas,Marc)  
 new optimizer operation weights(Vadim)  
 new psql \z grant/permit option(Marc)  
 new MONEY data type(D'Arcy,Thomas)  
 tcp socket communication speed improved(Vadim)  
 new VACUUM option for attribute statistics, and for certain columns (Vadim)  
 many geometric type improvements(Thomas,Keith)  
 additional regression tests(Thomas)  
 new datestyle variable(Thomas,Vadim,Martin)  
 more comparison operators for sorting types(Thomas)  
 new conversion functions(Thomas)  
 new more compact btree format(Vadim)  
 allow pg\_dumpall to preserve database ownership(Bruce)  
 new SET GEQO=# and R\_PLANS variable(Vadim)  
 old (!GEQO) optimizer can use right-sided plans (Vadim)  
 typechecking improvement in SQL parser(Bruce)  
 new SET, SHOW, RESET commands(Thomas,Vadim)  
 new \connect database USER option  
 new destroydb -i option (Igor)  
 new \dt and \di psql commands (Darren)  
 SELECT "\n" now escapes newline (A. Duursma)  
 new geometry conversion functions from old format (Thomas)

## Source tree changes

-----

new configuration script(Marc)  
 readline configuration option added(Marc)  
 OS-specific configuration options removed(Marc)  
 new OS-specific template files(Marc)

no more need to edit Makefile.global (Marc)  
re-arrange include files (Marc)  
nextstep patches (Gregor HOFFLEIT)  
removed Windows-specific code (Bruce)  
removed postmaster -e option, now only postgres -e option (Bruce)  
merge duplicate library code in front/backends (Martin)  
now works with eBones, international Kerberos (Jun)  
more shared library support  
c++ include file cleanup (Bruce)  
warn about buggy flex (Bruce)  
DG/UX, Ultrix, IRIX, AIX portability fixes

## E.112. Release 6.0

**Release date:** 1997-01-29

A dump/restore is required for those wishing to migrate data from previous releases of PostgreSQL.

### E.112.1. Migration from version 1.09 to version 6.0

This migration requires a complete dump of the 1.09 database and a restore of the database in 6.0.

### E.112.2. Migration from pre-1.09 to version 6.0

Those migrating from earlier 1.\* releases should first upgrade to 1.09 because the COPY output format was improved from the 1.02 release.

### E.112.3. Changes

Bug Fixes

-----

ALTER TABLE bug - running postgres process needs to re-read table definition

Allow vacuum to be run on one table or entire database (Bruce)

Array fixes

Fix array over-runs of memory writes (Kurt)

Fix elusive btree range/non-range bug (Dan)

Fix for hash indexes on some types like time and date

Fix for pg\_log size explosion

Fix permissions on lo\_export() (Bruce)

Fix uninitialized reads of memory (Kurt)

Fixed ALTER TABLE ... char(3) bug (Bruce)

Fixed a few small memory leaks  
Fixed EXPLAIN handling of options and changed full\_path option name  
Fixed output of group acl privileges  
Memory leaks (hunt and destroy with tools like Purify(Kurt))  
Minor improvements to rules system  
NOTIFY fixes  
New asserts for run-checking  
Overhauled parser/analyze code to properly report errors and increase speed  
Pg\_dump -d now handles NULL's properly(Bruce)  
Prevent SELECT NULL from crashing server (Bruce)  
Properly report errors when INSERT ... SELECT columns did not match  
Properly report errors when insert column names were not correct  
psql \g filename now works(Bruce)  
psql fixed problem with multiple statements on one line with multiple outputs  
Removed duplicate system OIDs  
SELECT \* INTO TABLE . GROUP/ORDER BY gives unlink error if table exists(Bruce)  
Several fixes for queries that crashed the backend  
Starting quote in insert string errors(Bruce)  
Submitting an empty query now returns empty status, not just " " query(Bruce)

#### Enhancements

-----

Add EXPLAIN manual page(Bruce)  
Add UNIQUE index capability(Dan)  
Add hostname/user level access control rather than just hostname and user  
Add synonym of != for <>(Bruce)  
Allow "select oid,\* from table"  
Allow BY,ORDER BY to specify columns by number, or by non-alias table.column(Bruce)  
Allow COPY from the frontend(Bryan)  
Allow GROUP BY to use alias column name(Bruce)  
Allow actual compression, not just reuse on the same page(Vadim)  
Allow installation-configuration option to auto-add all local users(Bryan)  
Allow libpq to distinguish between text value " and null(Bruce)  
Allow non-postgres users with createdb privs to destroydb's  
Allow restriction on who can create C functions(Bryan)  
Allow restriction on who can do backend COPY(Bryan)  
Can shrink tables, pg\_time and pg\_log(Vadim & Erich)  
Change debug level 2 to print queries only, changed debug heading layout(Bruce)  
Change default decimal constant representation from float4 to float8(Bruce)  
European date format now set when postmaster is started  
Execute lowercase function names if not found with exact case  
Fixes for aggregate/GROUP processing, allow 'select sum(func(x),sum(x+y) from z'  
Gist now included in the distribution(Marc)  
Ident authentication of local users(Bryan)  
Implement BETWEEN qualifier(Bruce)  
Implement IN qualifier(Bruce)  
libpq has PQgetisnull() (Bruce)  
libpq++ improvements  
New options to initdb(Bryan)  
Pg\_dump allow dump of OIDs(Bruce)  
Pg\_dump create indexes after tables are loaded for speed(Bruce)  
Pg\_dumpall dumps all databases, and the user table  
Pginterface additions for NULL values(Bruce)

Prevent postmaster from being run as root  
psql \h and \? is now readable(Bruce)  
psql allow backslashed, semicolons anywhere on the line(Bruce)  
psql changed command prompt for lines in query or in quotes(Bruce)  
psql char(3) now displays as (bp)char in \d output(Bruce)  
psql return code now more accurate(Bryan?)  
psql updated help syntax(Bruce)  
Re-visit and fix vacuum(Vadim)  
Reduce size of regression diffs, remove timezone name difference(Bruce)  
Remove compile-time parameters to enable binary distributions(Bryan)  
Reverse meaning of HBA masks(Bryan)  
Secure Authentication of local users(Bryan)  
Speed up vacuum(Vadim)  
Vacuum now had VERBOSE option(Bruce)

#### Source tree changes

-----  
All functions now have prototypes that are compared against the calls  
Allow asserts to be disabled easily from Makefile.global(Bruce)  
Change oid constants used in code to #define names  
Decoupled sparc and solaris defines(Kurt)  
Gcc -Wall compiles cleanly with warnings only from unfixable constructs  
Major include file reorganization/reduction(Marc)  
Make now stops on compile failure(Bryan)  
Makefile restructuring(Bryan, Marc)  
Merge bsdi\_2\_1 to bsdi(Bruce)  
Monitor program removed  
Name change from Postgres95 to PostgreSQL  
New config.h file(Marc, Bryan)  
PG\_VERSION now set to 6.0 and used by postmaster  
Portability additions, including Ultrix, DG/UX, AIX, and Solaris  
Reduced the number of #define's, centralized #define's  
Remove duplicate OIDS in system tables(Dan)  
Remove duplicate system catalog info or report mismatches(Dan)  
Removed many os-specific #define's  
Restructured object file generation/location(Bryan, Marc)  
Restructured port-specific file locations(Bryan, Marc)  
Unused/uninitialized variables corrected

## E.113. Release 1.09

**Release date:** 1996-11-04

Sorry, we didn't keep track of changes from 1.02 to 1.09. Some of the changes listed in 6.0 were actually included in the 1.02.1 to 1.09 releases.

## E.114. Release 1.02

**Release date:** 1996-08-01

### E.114.1. Migration from version 1.02 to version 1.02.1

Here is a new migration file for 1.02.1. It includes the 'copy' change and a script to convert old ASCII files.

**Note:** The following notes are for the benefit of users who want to migrate databases from Postgres95 1.01 and 1.02 to Postgres95 1.02.1.

If you are starting afresh with Postgres95 1.02.1 and do not need to migrate old databases, you do not need to read any further.

In order to upgrade older Postgres95 version 1.01 or 1.02 databases to version 1.02.1, the following steps are required:

1. Start up a new 1.02.1 postmaster
2. Add the new built-in functions and operators of 1.02.1 to 1.01 or 1.02 databases. This is done by running the new 1.02.1 server against your own 1.01 or 1.02 database and applying the queries attached at the end of the file. This can be done easily through `psql`. If your 1.01 or 1.02 database is named `testdb` and you have cut the commands from the end of this file and saved them in `addfunc.sql`:

```
% psql testdb -f addfunc.sql
```

Those upgrading 1.02 databases will get a warning when executing the last two statements in the file because they are already present in 1.02. This is not a cause for concern.

### E.114.2. Dump/Reload Procedure

If you are trying to reload a `pg_dump` or text-mode, `copy tablename to stdout` generated with a previous version, you will need to run the attached `sed` script on the ASCII file before loading it into the database. The old format used '.' as end-of-data, while '\.' is now the end-of-data marker. Also, empty strings are now loaded in as '' rather than NULL. See the copy manual page for full details.

```
sed 's/^\.$/\./g' <in_file >out_file
```

If you are loading an older binary copy or non-stdout copy, there is no end-of-data character, and hence no conversion necessary.

```
-- following lines added by agc to reflect the case-insensitive
-- regexp searching for varchar (in 1.02), and bpchar (in 1.02.1)
create operator ~* (leftarg = bpchar, rightarg = text, procedure = texticregexe);
create operator !~* (leftarg = bpchar, rightarg = text, procedure = texticregexne);
```

```
create operator ~* (leftarg = varchar, rightarg = text, procedure = texticregexeq);
create operator !~* (leftarg = varchar, rightarg = text, procedure = texticregexne);
```

## **E.114.3. Changes**

Source code maintenance and development

- \* worldwide team of volunteers
- \* the source tree now in CVS at ftp.ki.net

Enhancements

- \* psql (and underlying libpq library) now has many more options for formatting output, including HTML
- \* pg\_dump now output the schema and/or the data, with many fixes to enhance completeness.
- \* psql used in place of monitor in administration shell scripts. monitor to be deprecated in next release.
- \* date/time functions enhanced
- \* NULL insert/update/comparison fixed/enhanced
- \* TCL/TK lib and shell fixed to work with both tck7.4/tk4.0 and tcl7.5/tk4.1

Bug Fixes (almost too numerous to mention)

- \* indexes
- \* storage management
- \* check for NULL pointer before dereferencing
- \* Makefile fixes

New Ports

- \* added SolarisX86 port
- \* added BSD/OS 2.1 port
- \* added DG/UX port

## **E.115. Release 1.01**

**Release date:** 1996-02-23

### **E.115.1. Migration from version 1.0 to version 1.01**

The following notes are for the benefit of users who want to migrate databases from Postgres95 1.0 to Postgres95 1.01.

If you are starting afresh with Postgres95 1.01 and do not need to migrate old databases, you do not need to read any further.

In order to Postgres95 version 1.01 with databases created with Postgres95 version 1.0, the following steps are required:

1. Set the definition of `NAMEDATALEN` in `src/Makefile.global` to 16 and `OIDNAMELEN` to 20.
2. Decide whether you want to use Host based authentication.
  - a. If you do, you must create a file name `pg_hba` in your top-level data directory (typically the value of your `$PGDATA`). `src/libpq/pg_hba` shows an example syntax.
  - b. If you do not want host-based authentication, you can comment out the line:

```
HBA = 1
in src/Makefile.global
```

Note that host-based authentication is turned on by default, and if you do not take steps A or B above, the out-of-the-box 1.01 will not allow you to connect to 1.0 databases.

3. Compile and install 1.01, but DO NOT do the `initdb` step.
4. Before doing anything else, terminate your 1.0 postmaster, and backup your existing `$PGDATA` directory.
5. Set your `PGDATA` environment variable to your 1.0 databases, but set up path up so that 1.01 binaries are being used.
6. Modify the file `$PGDATA/PG_VERSION` from 5.0 to 5.1
7. Start up a new 1.01 postmaster
8. Add the new built-in functions and operators of 1.01 to 1.0 databases. This is done by running the new 1.01 server against your own 1.0 database and applying the queries attached and saving in the file `1.0_to_1.01.sql`. This can be done easily through `psql`. If your 1.0 database is name `testdb`:

```
% psql testdb -f 1.0_to_1.01.sql
```

and then execute the following commands (cut and paste from here):

```
-- add builtin functions that are new to 1.01
```

```
create function int4eqoid (int4, oid) returns bool as 'foo'
language 'internal';
create function oideqint4 (oid, int4) returns bool as 'foo'
language 'internal';
create function char2icregexeq (char2, text) returns bool as 'foo'
language 'internal';
create function char2icregexne (char2, text) returns bool as 'foo'
language 'internal';
create function char4icregexeq (char4, text) returns bool as 'foo'
language 'internal';
create function char4icregexne (char4, text) returns bool as 'foo'
language 'internal';
create function char8icregexeq (char8, text) returns bool as 'foo'
language 'internal';
create function char8icregexne (char8, text) returns bool as 'foo'
language 'internal';
```

```

create function char16icregexeq (char16, text) returns bool as 'foo'
language 'internal';
create function char16icregexne (char16, text) returns bool as 'foo'
language 'internal';
create function texticregexeq (text, text) returns bool as 'foo'
language 'internal';
create function texticregexne (text, text) returns bool as 'foo'
language 'internal';

-- add builtin functions that are new to 1.01

create operator = (leftarg = int4, rightarg = oid, procedure = int4eqoid);
create operator = (leftarg = oid, rightarg = int4, procedure = oideqint4);
create operator ~* (leftarg = char2, rightarg = text, procedure = char2icregexeq);
create operator !~* (leftarg = char2, rightarg = text, procedure = char2icregexne);
create operator ~* (leftarg = char4, rightarg = text, procedure = char4icregexeq);
create operator !~* (leftarg = char4, rightarg = text, procedure = char4icregexne);
create operator ~* (leftarg = char8, rightarg = text, procedure = char8icregexeq);
create operator !~* (leftarg = char8, rightarg = text, procedure = char8icregexne);
create operator ~* (leftarg = char16, rightarg = text, procedure = char16icregexeq);
create operator !~* (leftarg = char16, rightarg = text, procedure = char16icregexne);
create operator ~* (leftarg = text, rightarg = text, procedure = texticregexeq);
create operator !~* (leftarg = text, rightarg = text, procedure = texticregexne);

```

## E.115.2. Changes

### Incompatibilities:

- \* 1.01 is backwards compatible with 1.0 database provided the user follow the steps outlined in the MIGRATION\_from\_1.0\_to\_1.01 file. If those steps are not taken, 1.01 is not compatible with 1.0 database.

### Enhancements:

- \* added PQdisplayTuples() to libpq and changed monitor and psql to use it
- \* added NeXT port (requires SysVIPC implementation)
- \* added CAST .. AS ... syntax
- \* added ASC and DESC key words
- \* added 'internal' as a possible language for CREATE FUNCTION  
internal functions are C functions which have been statically linked into the postgres backend.
- \* a new type "name" has been added for system identifiers (table names, attribute names, etc.) This replaces the old char16 type. The of name is set by the NAMEDATALEN #define in src/Makefile.global
- \* a readable reference manual that describes the query language.
- \* added host-based access control. A configuration file (\$PGDATA/pg\_hba) is used to hold the configuration data. If host-based access control is not desired, comment out HBA=1 in src/Makefile.global.
- \* changed regex handling to be uniform use of Henry Spencer's regex code regardless of platform. The regex code is included in the distribution
- \* added functions and operators for case-insensitive regular expressions. The operators are ~\* and !~\*.

- \* `pg_dump` uses COPY instead of SELECT loop for better performance

Bug fixes:

- \* fixed an optimizer bug that was causing core dumps when functions calls were used in comparisons in the WHERE clause
- \* changed all uses of `getuid` to `geteuid` so that effective uids are used
- \* `psql` now returns non-zero status on errors when using `-c`
- \* applied public patches 1-14

## E.116. Release 1.0

**Release date:** 1995-09-05

### E.116.1. Changes

Copyright change:

- \* The copyright of Postgres 1.0 has been loosened to be freely modifiable and modifiable for any purpose. Please read the COPYRIGHT file.
- Thanks to Professor Michael Stonebraker for making this possible.

Incompatibilities:

- \* date formats have to be MM-DD-YYYY (or DD-MM-YYYY if you're using EUROPEAN STYLE). This follows SQL-92 specs.
- \* "delimiters" is now a key word

Enhancements:

- \* sql LIKE syntax has been added
- \* copy command now takes an optional USING DELIMITER specification. delimiters can be any single-character string.
- \* IRIX 5.3 port has been added.  
Thanks to Paul Walmsley and others.
- \* updated `pg_dump` to work with new `libpq`
- \* `\d` has been added `psql`  
Thanks to Keith Parks
- \* regexp performance for architectures that use POSIX regex has been improved due to caching of precompiled patterns.  
Thanks to Alistair Crooks
- \* a new version of `libpq++`  
Thanks to William Wanders

Bug fixes:

- \* arbitrary userids can be specified in the `createuser` script
- \* `\c` to connect to other databases in `psql` now works.
- \* bad `pg_proc` entry for `float4inc()` is fixed

- \* users with usecreatedb field set can now create databases without having to be usesuper
- \* remove access control entries when the entry no longer has any privileges
- \* fixed non-portable datetimes implementation
- \* added kerberos flags to the src/backend/Makefile
- \* libpq now works with kerberos
- \* typographic errors in the user manual have been corrected.
- \* btrees with multiple index never worked, now we tell you they don't work when you try to use them

## E.117. Postgres95 Release 0.03

**Release date:** 1995-07-21

### E.117.1. Changes

Incompatible changes:

- \* BETA-0.3 IS INCOMPATIBLE WITH DATABASES CREATED WITH PREVIOUS VERSIONS (due to system catalog changes and indexing structure changes).
- \* double-quote (") is deprecated as a quoting character for string literals; you need to convert them to single quotes (').
- \* name of aggregates (eg. int4sum) are renamed in accordance with the SQL standard (eg. sum).
- \* CHANGE ACL syntax is replaced by GRANT/REVOKE syntax.
- \* float literals (eg. 3.14) are now of type float4 (instead of float8 in previous releases); you might have to do typecasting if you depend on it being of type float8. If you neglect to do the typecasting and you assign a float literal to a field of type float8, you might get incorrect values stored!
- \* LIBPQ has been totally revamped so that frontend applications can connect to multiple backends
- \* the usesysid field in pg\_user has been changed from int2 to int4 to allow wider range of Unix user ids.
- \* the netbsd/freebsd/bsd o/s ports have been consolidated into a single BSD44\_derived port. (thanks to Alistair Crooks)

SQL standard-compliance (the following details changes that makes postgres95 more compliant to the SQL-92 standard):

- \* the following SQL types are now built-in: smallint, int(eger), float, real, char(N), varchar(N), date and time.

The following are aliases to existing postgres types:

smallint -> int2

```
integer, int -> int4
float, real  -> float4
```

char(N) and varchar(N) are implemented as truncated text types. In addition, char(N) does blank-padding.

- \* single-quote (') is used for quoting string literals; " (in addition to \') is supported as means of inserting a single quote in a string
- \* SQL standard aggregate names (MAX, MIN, AVG, SUM, COUNT) are used (Also, aggregates can now be overloaded, i.e. you can define your own MAX aggregate to take in a user-defined type.)
- \* CHANGE ACL removed. GRANT/REVOKE syntax added.
  - Privileges can be given to a group using the "GROUP" key word.

For example:

```
GRANT SELECT ON foobar TO GROUP my_group;
```

The key word 'PUBLIC' is also supported to mean all users.

Privileges can only be granted or revoked to one user or group at a time.

"WITH GRANT OPTION" is not supported. Only class owners can change access control

- The default access control is to grant users readonly access. You must explicitly grant insert/update access to users. To change this, modify the line in
 

```
src/backend/utils/acl.h
```

 that defines ACL\_WORLD\_DEFAULT

#### Bug fixes:

- \* the bug where aggregates of empty tables were not run has been fixed. Now, aggregates run on empty tables will return the initial conditions of the aggregates. Thus, COUNT of an empty table will now properly return 0. MAX/MIN of an empty table will return a row of value NULL.
- \* allow the use of \; inside the monitor
- \* the LISTEN/NOTIFY asynchronous notification mechanism now work
- \* NOTIFY in rule action bodies now work
- \* hash indexes work, and access methods in general should perform better. creation of large btree indexes should be much faster. (thanks to Paul Aoki)

#### Other changes and enhancements:

- \* addition of an EXPLAIN statement used for explaining the query execution plan (eg. "EXPLAIN SELECT \* FROM EMP" prints out the execution plan for the query).
- \* WARN and NOTICE messages no longer have timestamps on them. To turn on timestamps of error messages, uncomment the line in
 

```
src/backend/utils/elog.h:
/* define ELOG_TIMESTAMPS */
```
- \* On an access control violation, the message
 

```
"Either no such class or insufficient privilege"
```

 will be given. This is the same message that is returned when a class is not found. This dissuades non-privileged users from guessing the existence of privileged classes.
- \* some additional system catalog changes have been made that are not visible to the user.

libpgtcl changes:

- \* The -oid option has been added to the "pg\_result" tcl command. pg\_result -oid returns oid of the last row inserted. If the last command was not an INSERT, then pg\_result -oid returns "".
- \* the large object interface is available as pg\_lo\* tcl commands: pg\_lo\_open, pg\_lo\_close, pg\_lo\_creat, etc.

Portability enhancements and New Ports:

- \* flex/lex problems have been cleared up. Now, you should be able to use flex instead of lex on any platforms. We no longer make assumptions of what lexer you use based on the platform you use.
- \* The Linux-ELF port is now supported. Various configuration have been tested: The following configuration is known to work:  
kernel 1.2.10, gcc 2.6.3, libc 4.7.2, flex 2.5.2, bison 1.24  
with everything in ELF format,

New utilities:

- \* ipcclean added to the distribution  
ipcclean usually does not need to be run, but if your backend crashes and leaves shared memory segments hanging around, ipcclean will clean them up for you.

New documentation:

- \* the user manual has been revised and libpq documentation added.

## E.118. Postgres95 Release 0.02

**Release date:** 1995-05-25

### E.118.1. Changes

Incompatible changes:

- \* The SQL statement for creating a database is 'CREATE DATABASE' instead of 'CREATEDB'. Similarly, dropping a database is 'DROP DATABASE' instead of 'DESTROYDB'. However, the names of the executables 'createdb' and 'destroydb' remain the same.

New tools:

- \* pgperl - a Perl (4.036) interface to Postgres95
- \* pg\_dump - a utility for dumping out a postgres database into a script file containing query commands. The script files are in a ASCII format and can be used to reconstruct the database, even on other machines and other architectures. (Also good for converting

a Postgres 4.2 database to Postgres95 database.)

The following ports have been incorporated into postgres95-beta-0.02:

- \* the NetBSD port by Alistair Crooks
- \* the AIX port by Mike Tung
- \* the Windows NT port by Jon Forrest (more stuff but not done yet)
- \* the Linux ELF port by Brian Gallew

The following bugs have been fixed in postgres95-beta-0.02:

- \* new lines not escaped in COPY OUT and problem with COPY OUT when first attribute is a '.'
- \* cannot type return to use the default user id in createuser
- \* SELECT DISTINCT on big tables crashes
- \* Linux installation problems
- \* monitor doesn't allow use of 'localhost' as PGHOST
- \* psql core dumps when doing \c or \l
- \* the "pgtclsh" target missing from src/bin/pgtclsh/Makefile
- \* libpgtcl has a hard-wired default port number
- \* SELECT DISTINCT INTO TABLE hangs
- \* CREATE TYPE doesn't accept 'variable' as the internallength
- \* wrong result using more than 1 aggregate in a SELECT

## **E.119. Postgres95 Release 0.01**

**Release date:** 1995-05-01

Initial release.

## Appendix F. Additional Supplied Modules

This appendix contains information regarding the modules that can be found in the `contrib` directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

When building from the source distribution, these modules are not built automatically. You can build and install all of them by running

```
gmake
gmake install
```

in the `contrib` directory of a configured source tree; or to build and install just one selected module, do the same in that module's subdirectory. Many of the modules have regression tests, which can be executed by running

```
gmake installcheck
```

once you have a PostgreSQL server running. (Note that `gmake check` is not supported; you must have an operational database server to perform these tests, and you must have built and installed the module(s) to be tested.)

If you are using a pre-packaged version of PostgreSQL, these modules are typically made available as a separate subpackage, such as `postgresql-contrib`.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new objects in the database system by running the SQL commands in the `.sql` file supplied by the module. For example,

```
psql -d dbname -f $SHAREDIR/contrib/module.sql
```

Here, `$SHAREDIR` means the installation's "share" directory (`pg_config --sharedir` will tell you what this is). In most cases the script must be run by a database superuser.

You need to run the `.sql` file in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the module will be copied into subsequently-created databases by default.

You can modify the first command in the `.sql` file to determine which schema within the database the module's objects will be created in. By default, they will be placed in `public`.

After a major-version upgrade of PostgreSQL, run the installation script again, even though the module's objects might have been brought forward from the old installation by dump and restore. This ensures that any new functions will be available and any needed corrections will be applied.

## F.1. adminpack

`adminpack` provides a number of support functions which `pgAdmin` and other administration and management tools can use to provide additional functionality, such as remote management of server log files.

### F.1.1. Functions implemented

The functions implemented by `adminpack` can only be run by a superuser. Here's a list of these functions:

```
int8 pg_catalog.pg_file_write(fname text, data text, append bool)
bool pg_catalog.pg_file_rename(oldname text, newname text, archivename text)
bool pg_catalog.pg_file_rename(oldname text, newname text)
bool pg_catalog.pg_file_unlink(fname text)
setof record pg_catalog.pg_logdir_ls()

/* Renaming of existing backend functions for pgAdmin compatibility */
int8 pg_catalog.pg_file_read(fname text, data text, append bool)
bigint pg_catalog.pg_file_length(text)
int4 pg_catalog.pg_logfile_rotate()
```

## F.2. btree\_gist

`btree_gist` provides sample GiST operator classes that implement B-Tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `inet`, and `cidr`.

In general, these operator classes will not outperform the equivalent standard `btree` index methods, and they lack one major feature of the standard `btree` code: the ability to enforce uniqueness. However, they are useful for GiST testing and as a base for developing other GiST operator classes.

### F.2.1. Example usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING gist (a);
-- query
SELECT * FROM test WHERE a < 10;
```

## F.2.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), and Janko Richter (<jankorichter@yahoo.de>). See <http://www.sai.msu.su/~megeera/postgres/gist> for additional information.

## F.3. chkpass

This module implements a data type `chkpass` that is designed for storing encrypted passwords. Each password is automatically converted to encrypted form upon entry, and is always stored encrypted. To compare, simply compare against a clear text password and the comparison function will encrypt it before comparing.

There are provisions in the code to report an error if the password is determined to be easily crackable. However, this is currently just a stub that does nothing.

If you precede an input string with a colon, it is assumed to be an already-encrypted password, and is stored without further encryption. This allows entry of previously-encrypted passwords.

On output, a colon is prepended. This makes it possible to dump and reload passwords without re-encrypting them. If you want the encrypted password without the colon then use the `raw()` function. This allows you to use the type with things like Apache's `Auth_PostgreSQL` module.

The encryption uses the standard Unix function `crypt()`, and so it suffers from all the usual limitations of that function; notably that only the first eight characters of a password are considered.

Note that the `chkpass` data type is not indexable.

Sample usage:

```
test=# create table test (p chkpass);
CREATE TABLE
test=# insert into test values ('hello');
INSERT 0 1
test=# select * from test;
      p
-----
:dVGkpXdOrE3ko
(1 row)

test=# select raw(p) from test;
      raw
-----
dVGkpXdOrE3ko
(1 row)

test=# select p = 'hello' from test;
?column?
-----
t
(1 row)
```

```
test=# select p = 'goodbye' from test;
?column?
-----
f
(1 row)
```

### F.3.1. Author

D'Arcy J.M. Cain (<darcy@druid.net>)

## F.4. cube

This module implements a data type `cube` for representing multi-dimensional cubes.

### F.4.1. Syntax

The following are valid external representations for the `cube` type.  $x$ ,  $y$ , etc denote floating-point numbers:

**Table F-1. Cube external representations**

$x$	A one-dimensional point (or, zero-length one-dimensional interval)
$(x)$	Same as above
$x1, x2, \dots, xn$	A point in n-dimensional space, represented internally as a zero-volume cube
$(x1, x2, \dots, xn)$	Same as above
$(x), (y)$	A one-dimensional interval starting at $x$ and ending at $y$ or vice versa; the order does not matter
$[(x), (y)]$	Same as above
$(x1, \dots, xn), (y1, \dots, yn)$	An n-dimensional cube represented by a pair of its diagonally opposite corners
$[(x1, \dots, xn), (y1, \dots, yn)]$	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation.

White space is ignored, so  $[(x), (y)]$  is the same as  $[(x), (y)]$ .

### F.4.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

### F.4.3. Usage

The `cube` module includes a GiST index operator class for `cube` values. The operators supported by the GiST opclass include:

- `a = b`                                      Same as  
The cubes `a` and `b` are identical.
- `a && b`                                      Overlaps  
The cubes `a` and `b` overlap.
- `a @> b`                                      Contains  
The cube `a` contains the cube `b`.
- `a <@ b`                                      Contained in  
The cube `a` is contained in the cube `b`.

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric datatypes!)

The standard B-tree operators are also provided, for example

- `[a, b] < [c, d]`                                      Less than
- `[a, b] > [c, d]`                                      Greater than

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

The following functions are available:

**Table F-2. Cube functions**

<code>cube(float8)</code> returns cube	Makes a one dimensional cube with both coordinates the same. <code>cube(1) == '(1)'</code>
<code>cube(float8, float8)</code> returns cube	Makes a one dimensional cube. <code>cube(1,2) == '(1),(2)'</code>
<code>cube(float8[])</code> returns cube	Makes a zero-volume cube using the coordinates defined by the array. <code>cube(ARRAY[1,2]) == '(1,2)'</code>
<code>cube(float8[], float8[])</code> returns cube	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length. <code>cube('{1,2}'::float[], '{3,4}'::float[]) == '(1,2),(3,4)'</code>

<code>cube(cube, float8) returns cube</code>	Makes a new cube by adding a dimension on to an existing cube with the same values for both parts of the new coordinate. This is useful for building cubes piece by piece from calculated values. <code>cube(' (1)', 2) == ' (1,2), (1,2) '</code>
<code>cube(cube, float8, float8) returns cube</code>	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. <code>cube(' (1,2)', 3, 4) == ' (1,3), (2,4) '</code>
<code>cube_dim(cube) returns int</code>	Returns the number of dimensions of the cube
<code>cube_ll_coord(cube, int) returns double</code>	Returns the n'th coordinate value for the lower left corner of a cube
<code>cube_ur_coord(cube, int) returns double</code>	Returns the n'th coordinate value for the upper right corner of a cube
<code>cube_is_point(cube) returns bool</code>	Returns true if a cube is a point, that is, the two defining corners are the same.
<code>cube_distance(cube, cube) returns double</code>	Returns the distance between two cubes. If both cubes are points, this is the normal distance function.
<code>cube_subset(cube, int[]) returns cube</code>	Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to find both the LL and UR coordinates of a single dimension, e.g. <code>cube_subset(cube(' (1,3,5), (6,7,8) '), ARRAY[2]) = ' (3), (7) '</code> . Or can be used to drop dimensions, or reorder them as desired, e.g. <code>cube_subset(cube(' (1,3,5), (6,7,8) '), ARRAY[3,2,1,1]) = ' (5, 3, 1, 1), (8, 7, 6, 6) '</code> .
<code>cube_union(cube, cube) returns cube</code>	Produces the union of two cubes
<code>cube_inter(cube, cube) returns cube</code>	Produces the intersection of two cubes
<code>cube_enlarge(cube c, double r, int n) returns cube</code>	Increases the size of a cube by a specified radius in at least n dimensions. If the radius is negative the cube is shrunk instead. This is useful for creating bounding boxes around a point for searching for nearby points. All defined dimensions are changed by the radius r. LL coordinates are decreased by r and UR coordinates are increased by r. If a LL coordinate is increased to larger than the corresponding UR coordinate (this can only happen when $r < 0$ ) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being increased ( $r \geq 0$ ) then 0 is used as the base for the extra coordinates.

## F.4.4. Defaults

I believe this union:

```
select cube_union(' (0,5,2), (2,3,1)', '0');
cube_union
-----
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter(' (0,-1), (1,1)', ' (-2), (2)' );
cube_inter
-----
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union(' (0,5,2), (2,3,1)', ' (0,0,0), (0,0,0)' );
cube_inter(' (0,-1), (1,1)', ' (-2,0), (2,0)' );
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains(' (0,0), (1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

## F.4.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

## F.4.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<http://db.cs.berkeley.edu/~jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student, Andy Dong (<http://best.me.berkeley.edu/~adong/>), for his example written for Illustra,

<http://garcia.me.berkeley.edu/~adong/rtree>. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <[bruno@wolff.to](mailto:bruno@wolff.to)> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <[josh@root.net](mailto:josh@root.net)> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

## F.5. dblink

`dblink` is a module which supports connections to other PostgreSQL databases from within a database session.

### `dblink_connect`

#### Name

`dblink_connect` — opens a persistent connection to a remote database

#### Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

#### Description

`dblink_connect()` establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

## Arguments

`conname`

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

`connstr`

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd`. For details see `PQconnectdb` in Section 30.1.

## Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

## Notes

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

## Example

```
select dblink_connect('dbname=postgres');
 dblink_connect
-----
      OK
(1 row)

select dblink_connect('myconn', 'dbname=postgres');
 dblink_connect
-----
      OK
(1 row)
```

# dblink\_connect\_u

## Name

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

## Synopsis

```
dblink_connect_u(text connstr) returns text
dblink_connect_u(text connname, text connstr) returns text
```

## Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care.

For further details see `dblink_connect()`.

# dblink\_disconnect

## Name

`dblink_disconnect` — closes a persistent connection to a remote database

## Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

## Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

## Arguments

`connname`

The name of a named connection to be closed.

## Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

## Example

```
test=# select dblink_disconnect();
 dblink_disconnect
-----
OK
(1 row)

select dblink_disconnect('myconn');
 dblink_disconnect
-----
OK
(1 row)
```

# dblink

## Name

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

`connname`

Name of the connection to use; omit this parameter to use the unnamed connection.

`connstr`

A connection info string, as previously described for `dblink_connect`.

`sql`

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must

specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb', 'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what `*` should expand to, and what `proname` in the `WHERE` clause refers to, in advance of trying to execute the function. At runtime, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

## Notes

`dblink` fetches the entire remote query result before returning any of it to the local system. If the query is expected to return a large number of rows, it's better to open it as a cursor with `dblink_open` and then fetch a manageable number of rows at a time.

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
create view myremote_pg_proc as
select *
from dblink('dbname=postgres', 'select proname, prosrc from pg_proc')
as t1(proname name, prosrc text);

select * from myremote_pg_proc where proname like 'bytea%';
```

## Example

```
select * from dblink('dbname=postgres', 'select proname, prosrc from pg_proc')
as t1(proname name, prosrc text) where proname like 'bytea%';
proname | prosrc
-----+-----
byteacat | byteacat
byteaeq  | byteaeq
bytealt  | bytealt
byteale  | byteale
byteagt  | byteagt
byteage  | byteage
byteane  | byteane
```

```

byteacmp | byteacmp
bytealike | bytealike
byteanlike | byteanlike
byteain | byteain
byteaout | byteaout
(12 rows)

```

```

select dblink_connect('dbname=postgres');
 dblink_connect
-----
OK
(1 row)

```

```

select * from dblink('select proname, prosrc from pg_proc')
as t1(proname name, prosrc text) where proname like 'bytea%';
 proname | prosrc
-----+-----
byteacat | byteacat
byteaeq | byteaeq
bytealt | bytealt
byteale | byteale
byteagt | byteagt
byteage | byteage
byteane | byteane
byteacmp | byteacmp
bytealike | bytealike
byteanlike | byteanlike
byteain | byteain
byteaout | byteaout
(12 rows)

```

```

select dblink_connect('myconn', 'dbname=regression');
 dblink_connect
-----
OK
(1 row)

```

```

select * from dblink('myconn', 'select proname, prosrc from pg_proc')
as t1(proname name, prosrc text) where proname like 'bytea%';
 proname | prosrc
-----+-----
bytearecv | bytearecv
byteasend | byteasend
byteale | byteale
byteagt | byteagt
byteage | byteage
byteane | byteane
byteacmp | byteacmp
bytealike | bytealike
byteanlike | byteanlike
byteacat | byteacat
byteaeq | byteaeq
bytealt | bytealt

```

```
byteain      | byteain  
byteaout     | byteaout  
(14 rows)
```

# dblink\_exec

## Name

`dblink_exec` — executes a command in a remote database

## Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

## Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

`connname`

Name of the connection to use; omit this parameter to use the unnamed connection.

`connstr`

A connection info string, as previously described for `dblink_connect`.

`sql`

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0,'a',{ "a0","b0","c0" })`.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either the command's status string or `ERROR`.

## Example

```

select dblink_connect('dbname=dblink_test_slave');
dblink_connect
-----
OK
(1 row)

select dblink_exec('insert into foo values(21,"z","{a0","b0","c0}")');
dblink_exec
-----
INSERT 943366 1
(1 row)

select dblink_connect('myconn', 'dbname=regression');
dblink_connect
-----
OK
(1 row)

select dblink_exec('myconn', 'insert into foo values(21,"z","{a0","b0","c0}")');
dblink_exec
-----
INSERT 6432584 1
(1 row)

select dblink_exec('myconn', 'insert into pg_class values ("foo"),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

dblink_exec
-----
ERROR
(1 row)

```

# dblink\_open

## Name

`dblink_open` — opens a cursor in a remote database

## Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns te
```

## Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

## Arguments

`connname`

Name of the connection to use; omit this parameter to use the unnamed connection.

`cursorname`

The name to assign to this cursor.

`sql`

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will

be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

## Example

```
test=# select dblink_connect('dbname=postgres');
 dblink_connect
-----
      OK
(1 row)

test=# select dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
      OK
(1 row)
```

# dblink\_fetch

## Name

`dblink_fetch` — returns rows from an open cursor in a remote database

## Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) return
```

## Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

## Arguments

`connname`

Name of the connection to use; omit this parameter to use the unnamed connection.

`cursorname`

The name of the cursor to fetch from.

`howmany`

The maximum number of rows to retrieve. The next `howmany` rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

## Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still

advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

## Example

```
test=# select dblink_connect('dbname=postgres');
```

```
dblink_connect
```

```
-----
```

```
OK
```

```
(1 row)
```

```
test=# select dblink_open('foo', 'select proname, prosrc from pg_proc where proname like "');
```

```
dblink_open
```

```
-----
```

```
OK
```

```
(1 row)
```

```
test=# select * from dblink_fetch('foo', 5) as (funcname name, source text);
```

```
funcname | source
```

```
-----+-----
```

```
byteacat | byteacat
```

```
byteacmp | byteacmp
```

```
byteaeq  | byteaeq
```

```
byteage  | byteage
```

```
byteagt  | byteagt
```

```
(5 rows)
```

```
test=# select * from dblink_fetch('foo', 5) as (funcname name, source text);
```

```
funcname | source
```

```
-----+-----
```

```
byteain  | byteain
```

```
byteale  | byteale
```

```
bytealike | bytealike
```

```
bytealt  | bytealt
```

```
byteane  | byteane
```

```
(5 rows)
```

```
test=# select * from dblink_fetch('foo', 5) as (funcname name, source text);
```

```
funcname | source
```

```
-----+-----
```

```
byteanlike | byteanlike
```

```
byteaout   | byteaout
```

```
(2 rows)
```

```
test=# select * from dblink_fetch('foo', 5) as (funcname name, source text);
```

```
funcname | source
```

```
-----+-----
```

```
(0 rows)
```

# dblink\_close

## Name

`dblink_close` — closes a cursor in a remote database

## Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

## Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

## Arguments

`connname`

Name of the connection to use; omit this parameter to use the unnamed connection.

`cursorname`

The name of the cursor to close.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

## Example

```
test=# select dblink_connect('dbname=postgres');
 dblink_connect
-----
      OK
(1 row)

test=# select dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
      OK
(1 row)

test=# select dblink_close('foo');
 dblink_close
-----
      OK
(1 row)
```

# dblink\_get\_connections

## Name

`dblink_get_connections` — returns the names of all open named dblink connections

## Synopsis

```
dblink_get_connections() returns text[]
```

## Description

`dblink_get_connections` returns an array of the names of all open named dblink connections.

## Return Value

Returns a text array of connection names, or NULL if none.

## Example

```
SELECT dblink_get_connections();
```

# dblink\_error\_message

## Name

`dblink_error_message` — gets last error message on the named connection

## Synopsis

```
dblink_error_message(text connname) returns text
```

## Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

## Arguments

`connname`

Name of the connection to use.

## Return Value

Returns last error message, or an empty string if there has been no error in this connection.

## Example

```
SELECT dblink_error_message('dtest1');
```

# dblink\_send\_query

## Name

`dblink_send_query` — sends an async query to a remote database

## Synopsis

```
dblink_send_query(text connname, text sql) returns int
```

## Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

## Arguments

`connname`

Name of the connection to use.

`sql`

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

## Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

## Example

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

# dblink\_is\_busy

## Name

`dblink_is_busy` — checks if connection is busy with an async query

## Synopsis

```
dblink_is_busy(text connname) returns int
```

## Description

`dblink_is_busy` tests whether an async query is in progress.

## Arguments

`connname`

Name of the connection to check.

## Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

## Example

```
SELECT dblink_is_busy('dtest1');
```

# dblink\_get\_result

## Name

`dblink_get_result` — gets an async query result

## Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

## Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

## Arguments

`connname`

Name of the connection to use.

`fail_on_error`

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

## Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

## Example

```

contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * from
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3') as t1
t1
----
1
(1 row)

contrib_regression=# SELECT * from dblink_get_result('dtest1') as t1(f1 int, f2 text, f3
f1 | f2 | f3
----+----+-----
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * from dblink_get_result('dtest1') as t1(f1 int, f2 text, f3
f1 | f2 | f3
----+----+-----
(0 rows)

contrib_regression=# SELECT * from
dblink_send_query('dtest1', 'select * from foo where f1 < 3; select * from foo where f1
t1
----
1
(1 row)

contrib_regression=# SELECT * from dblink_get_result('dtest1') as t1(f1 int, f2 text, f3
f1 | f2 | f3
----+----+-----
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * from dblink_get_result('dtest1') as t1(f1 int, f2 text, f3
f1 | f2 | f3
----+----+-----
7 | h | {a7,b7,c7}
8 | i | {a8,b8,c8}
9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(4 rows)

contrib_regression=# SELECT * from dblink_get_result('dtest1') as t1(f1 int, f2 text, f3

```

```
  f1 | f2 | f3  
-----+-----+-----  
(0 rows)
```

# dblink\_cancel\_query

## Name

`dblink_cancel_query` — cancels any active query on the named connection

## Synopsis

```
dblink_cancel_query(text connname) returns text
```

## Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

## Arguments

`connname`

Name of the connection to use.

## Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

## Example

```
SELECT dblink_cancel_query('dtest1');
```

# dblink\_current\_query

## Name

`dblink_current_query` — returns the current query string

## Synopsis

```
dblink_current_query() returns text
```

## Description

Returns the currently executing interactive command string of the local database session, or NULL if it can't be determined. Note that this function is not really related to `dblink`'s other functionality. It is provided since it is sometimes useful in generating queries to be forwarded to remote databases.

## Return Value

Returns a copy of the currently executing query string.

## Example

```
test=# select dblink_current_query();
       dblink_current_query
-----
select dblink_current_query();
(1 row)
```

# dblink\_get\_pkey

## Name

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

## Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

## Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

## Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

## Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result rowtype is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

## Example

```
test=# create table foobar(f1 int, f2 int, f3 int,
test(#   primary key(f1,f2,f3));
CREATE TABLE
test=# select * from dblink_get_pkey('foobar');
   position | colname
-----+-----
         1 | f1
```

```
      2 | f2
      3 | f3
(3 rows)
```

# dblink\_build\_sql\_insert

## Name

`dblink_build_sql_insert` — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

## Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        int2 num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

## Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

## Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`src_pk_att_vals_array`

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

`tgt_pk_att_vals_array`

Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

## Return Value

Returns the requested SQL statement as text.

## Example

```
test=# select dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"a"}');
          dblink_build_sql_insert
-----
INSERT INTO foo(f1,f2,f3) VALUES('1','b"a','1')
(1 row)
```

# dblink\_build\_sql\_delete

## Name

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

## Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        int2 num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

## Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL `DELETE` command that will delete the row with the given primary key values.

## Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`tgt_pk_att_vals_array`

Values of the primary key fields to be used in the resulting `DELETE` command. Each field is represented in text form.

## Return Value

Returns the requested SQL statement as text.

## Example

```
test=# select dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');
          dblink_build_sql_delete
-----
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
```

# dblink\_build\_sql\_update

## Name

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

## Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        int2 num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

## Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

## Arguments

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

`primary_key_attnums`

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

`num_primary_key_atts`

The number of primary key fields.

`src_pk_att_vals_array`

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt\_pk\_att\_vals\_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

## Return Value

Returns the requested SQL statement as text.

## Example

```
test=# select dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
          dblink_build_sql_update
-----
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

## F.6. dict\_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

### F.6.1. Configuration

The dictionary accepts two options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

### F.6.2. Usage

Running the installation script creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
       ts_lexize
-----
{123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

## F.7. dict\_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

### F.7.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `keeporig` controls whether the original word is included (if `true`), or only its synonyms (if `false`). Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the PostgreSQL installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:

```
word syn1 syn2 syn3
```

- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$$SHAREDIR/tsearch_data/`, for an example.

### F.7.2. Usage

Running the installation script creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
           ts_lexize
-----
{word,syn1,syn2,syn3}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

## F.8. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` package (which *must* be installed before `earthdistance` can be installed). The second one is based on the built-in `point` datatype, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the PostGIS<sup>1</sup> project.)

### F.8.1. Cube-based earth distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The following functions are provided:

**Table F-3. Cube-based earthdistance functions**

Function	Returns	Description
<code>earth()</code>	<code>float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc(float8)</code>	<code>float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.

1. <http://www.postgis.org/>

Function	Returns	Description
<code>gc_to_sec(float8)</code>	<code>float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth(float8, float8)</code>	<code>earth</code>	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
<code>latitude(earth)</code>	<code>float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude(earth)</code>	<code>float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance(earth, earth)</code>	<code>float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box(earth, float8)</code>	<code>cube</code>	Returns a box suitable for an indexed search using the cube @> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

## F.8.2. Point-based earth distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided:

**Table F-4. Point-based earthdistance operators**

Operator	Returns	Description
----------	---------	-------------

Operator	Returns	Description
<code>point &lt;@&gt; point</code>	<code>float8</code>	Gives the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

## F.9. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

### F.9.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
```

```
SELECT * FROM s WHERE soundex(nm) = soundex('john');

SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

## F.9.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters.

Example:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');
 levenshtein
-----
                2
(1 row)
```

## F.9.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
      KM
(1 row)
```

### F.9.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# select dmetaphone('gumbo');
 dmetaphone
-----
      KMP
(1 row)
```

## F.10. hstore

This module implements a data type `hstore` for storing sets of (key,value) pairs within a single PostgreSQL data field. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data.

### F.10.1. hstore External Representation

The text representation of an `hstore` value includes zero or more `key => value` items, separated by commas. For example:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the items is not considered significant (and may not be reproduced on output). Whitespace between items or around the `=>` sign is ignored. Use double quotes if a key or value includes whitespace, comma, `=` or `>`. To include a double quote or a backslash in a key or value, precede it with another backslash. (Keep in mind that depending on the setting of `standard_conforming_strings`, you may need to double backslashes in SQL literal strings.)

A value (but not a key) can be a SQL NULL. This is represented as

```
key => NULL
```

The `NULL` keyword is not case-sensitive. Again, use double quotes if you want the string `null` to be treated as an ordinary data value.

Currently, double quotes are always used to surround key and value strings on output, even when this is not strictly necessary.

## F.10.2. hstore Operators and Functions

**Table F-5. hstore Operators**

Operator	Description	Example	Result
<code>hstore -&gt; text</code>	get value for key (null if not present)	<code>'a'=&gt;x, b=&gt;y'::hstore -&gt; 'a'</code>	<code>x</code>
<code>text =&gt; text</code>	make single-item hstore	<code>'a' =&gt; 'b'</code>	<code>"a"=&gt;"b"</code>
<code>hstore    hstore</code>	concatenation	<code>'a'=&gt;b, c=&gt;d'::hstore    'c'=&gt;x, d=&gt;q'::hstore</code>	<code>"a"=&gt;"b", "c"=&gt;"x", "d"=&gt;"q"</code>
<code>hstore ? text</code>	does hstore contain key?	<code>'a'=&gt;1'::hstore ? 'a'</code>	<code>t</code>
<code>hstore @&gt; hstore</code>	does left operand contain right?	<code>'a'=&gt;b, b=&gt;1, c=&gt;NULL'::hstore @&gt; 'b=&gt;1'</code>	<code>t</code>
<code>hstore &lt;@ hstore</code>	is left operand contained in right?	<code>'a'=&gt;c'::hstore &lt;@ 'a'=&gt;b, b=&gt;1, c=&gt;NULL'</code>	<code>f</code>

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric datatypes!)

**Table F-6. hstore Functions**

Function	Return Type	Description	Example	Result
<code>akeys(hstore)</code>	<code>text []</code>	get hstore's keys as array	<code>akeys('a'=&gt;1,b=&gt;2)</code>	<code>{a}</code>
<code>skeys(hstore)</code>	<code>setof text</code>	get hstore's keys as set	<code>skeys('a'=&gt;1,b=&gt;2)</code>	<code>{a}</code>
<code>avals(hstore)</code>	<code>text []</code>	get hstore's values as array	<code>avals('a'=&gt;1,b=&gt;2)</code>	<code>{1,2}</code>
<code>svals(hstore)</code>	<code>setof text</code>	get hstore's values as set	<code>svals('a'=&gt;1,b=&gt;2)</code>	<code>{1,2}</code>

Function	Return Type	Description	Example	Result
<code>each(hstore)</code>	<code>setof (key text, value text)</code>	get hstore's keys and values as set	<code>select * from each('a=&gt;1,b=&gt;2')</code>	<pre> key   value ----+----- a     1 b     2 </pre>
<code>exist(hstore,text)</code>	<code>boolean</code>	does hstore contain key?	<code>exist('a=&gt;1','a')</code>	
<code>defined(hstore,text)</code>	<code>boolean</code>	does hstore contain non-null value for key?	<code>defined('a=&gt;NULL','a')</code>	
<code>delete(hstore,text)</code>	<code>hstore</code>	delete any item matching key	<code>delete('a=&gt;1,b=&gt;2')</code>	<code>{} --&gt; {}</code>

### F.10.3. Indexes

`hstore` has index support for `@>` and `?` operators. You can use either GiST or GIN index types. For example:

```
CREATE INDEX hidx ON testhstore USING GIST(h);
```

```
CREATE INDEX hidx ON testhstore USING GIN(h);
```

### F.10.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || ('c' => '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

### F.10.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. Examples below demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key	count
line	883
query	207
pos	203
node	202
space	197
status	195
public	194
title	190
org	189
.....	

## F.10.6. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

## F.11. intagg

The `intagg` module provides an integer aggregator and an enumerator.

### F.11.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. Here is a not-tremendously-useful example:

```
test=# select int_array_aggregate(i) from
test=#   generate_series(1,10,2) i;
 int_array_aggregate
-----
 {1,3,5,7,9}
(1 row)
```

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. For example,

```
test=# select * from int_array_enum(array[1,3,5,7,9]);
 int_array_enum
-----
          1
          3
          5
          7
          9
(5 rows)
```

### F.11.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary as
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
  GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
      ON (summary.left = lefts.left)
  ) AS list
GROUP BY right
ORDER BY count DESC;
```

## F.12. intarray

The `intarray` module provides a number of useful functions and operators for manipulating one-dimensional arrays of integers. There is also support for indexed searches using some of the operators.

### F.12.1. intarray Functions and Operators

**Table F-7. intarray Functions**

Function	Return Type	Description	Example	Result
<code>icount(int[])</code>	<code>int</code>	number of elements in array	<code>icount (' {1,2,3}' : int[])</code>	<code>3</code>
<code>sort(int[], text dir)</code>	<code>int[]</code>	sort array — dir must be <code>asc</code> or <code>desc</code>	<code>sort (' {1,2,3}' : int[], 'desc')</code>	<code>{3,2,1}</code>
<code>sort(int[])</code>	<code>int[]</code>	sort in ascending order	<code>sort (array[11, 77, 44, 44, 77])</code>	<code>{11, 44, 44, 77, 77}</code>
<code>sort_asc(int[])</code>	<code>int[]</code>	sort in ascending order		
<code>sort_desc(int[])</code>	<code>int[]</code>	sort in descending order		
<code>uniq(int[])</code>	<code>int[]</code>	remove adjacent duplicates	<code>uniq (sort (' {1,2,3,2,2,13}' : int[]))</code>	<code>{1,2,3,13}</code>

Function	Return Type	Description	Example	Result
<code>idx(int[], int item)</code>	<code>int</code>	index of first element matching item (0 if none)	<code>idx(array[11, 22, 33, 22, 11], 22)</code>	
<code>subarray(int[], int start, int len)</code>	<code>int[]</code>	portion of array starting at position start, len elements	<code>subarray(' {1, 2, 3, 2, 3, 2} :int[]', 2, 3)</code>	
<code>subarray(int[], int start)</code>	<code>int[]</code>	portion of array starting at position start	<code>subarray(' {1, 2, 3, 2, 3, 2} :int[]', 2)</code>	
<code>intset(int)</code>	<code>int[]</code>	make single-element array	<code>intset(42)</code>	<code>{42}</code>

Table F-8. `intarray` Operators

Operator	Returns	Description
<code>int[] &amp;&amp; int[]</code>	<code>boolean</code>	overlap — <code>true</code> if arrays have at least one common element
<code>int[] @&gt; int[]</code>	<code>boolean</code>	contains — <code>true</code> if left array contains right array
<code>int[] &lt;@ int[]</code>	<code>boolean</code>	contained — <code>true</code> if left array is contained in right array
<code># int[]</code>	<code>int</code>	number of elements in array
<code>int[] # int</code>	<code>int</code>	index (same as <code>idx</code> function)
<code>int[] + int</code>	<code>int[]</code>	push element onto array (add it to end of array)
<code>int[] + int[]</code>	<code>int[]</code>	array concatenation (right array added to the end of left one)
<code>int[] - int</code>	<code>int[]</code>	remove entries matching right argument from array
<code>int[] - int[]</code>	<code>int[]</code>	remove elements of right array from left
<code>int[]   int</code>	<code>int[]</code>	union of arguments
<code>int[]   int[]</code>	<code>int[]</code>	union of arrays
<code>int[] &amp; int[]</code>	<code>int[]</code>	intersection of arrays
<code>int[] @@ query_int</code>	<code>boolean</code>	<code>true</code> if array satisfies query (see below)
<code>query_int ~~ int[]</code>	<code>boolean</code>	<code>true</code> if array satisfies query (commutator of @@)

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are

reversed from the convention formerly followed by the core geometric datatypes!)

The @@ and ~~ operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.12.2. Index Support

`intarray` provides index support for the &&, @>, <@, and @@ operators, as well as regular array equality. The implementation uses an RD-tree data structure with built-in lossy compression.

Two GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small and medium-size arrays, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large arrays.

There is also a non-default GIN operator class `gin__int_ops`.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.

## F.12.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__int_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

## F.12.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite. To run:

```
cd ../bench
createdb TEST
psql TEST < ../_int.sql
./create_test.pl | psql TEST
```

```
./bench.pl
```

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

## F.12.5. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.13. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input, and correctly hyphenated on output.

### F.13.1. Data types

**Table F-9. `isn` data types**

Data type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).

3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

### F.13.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

### F.13.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus btree and hash indexing support for all these datatypes. In addition there are several specialized functions. In this table, `isn` means any one of the module's data types:

**Table F-10. `isn` functions**

Function	Returns	Description
<code>isn_weak(boolean)</code>	boolean	Sets the weak input mode (returns new setting)
<code>isn_weak()</code>	boolean	Gets the current status of the weak mode
<code>make_valid(isn)</code>	isn	Validates an invalid number (clears the invalid flag)
<code>is_valid(isn)</code>	boolean	Checks for the presence of the invalid flag

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

### F.13.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');
```

```
--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

### F.13.5. Bibliography

The information to implement this module was collected from several sites, including:

```
http://www.isbn-international.org/
http://www.issn.org/
http://www.ismn-international.org/
http://www.wikipedia.org/
```

The prefixes used for hyphenation were also compiled from:

```
http://www.gsl.org/productssolutions/idkeys/support/prefix_list.html
http://www.isbn-international.org/en/identifiers.html
http://www.ismn-international.org/ranges.html
```

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

### F.13.6. Author

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman's isbn\_issn code.

## F.14. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

### F.14.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

### F.14.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title TEXT, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
  FOR EACH ROW EXECUTE PROCEDURE lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

### F.14.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the `contrib/vacuumlo` module (Section F.33) to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

### F.14.4. Author

Peter Mount <pete@retap.org.uk>

## F.15. Itree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

### F.15.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 bytes long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path must be less than 65Kb, but keeping it under 2Kb is preferable. In practice this is not a major limitation; for example, the longest label path in the DMOZ catalogue (<http://www.dmoz.org>) is about 240 bytes.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several datatypes:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (\*) matches zero or more labels. For example:

<code>foo</code>	<i>Match the exact label path foo</i>
<code>*.foo.*</code>	<i>Match any label path containing the label foo</i>
<code>*.foo</code>	<i>Match any label path whose last label is foo</i>

Star symbols can also be quantified to restrict how many labels they can match:

```

*{n}           Match exactly n labels
*{n,}          Match at least n labels
*{n,m}         Match at least n but not more than m labels
*{,m}          Match at most m labels -- same as  *{0,m}

```

There are several modifiers that can be put at the end of a non-star label in `lquery` to make it match more than just the exact match:

```

@             Match case-insensitively, for example a@ matches A
*             Match any label with this prefix, for example foo* matches foobar
%             Match initial underscore-separated words

```

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified labels separated with `|` (OR) to match any of those labels, and you can put `!` (NOT) at the start to match any label that doesn't match any of the alternatives.

Here's an annotated example of `lquery`:

```

Top.*{0,2}.sport*@.!football|tennis.Russ*|Spain
a.  b.      c.      d.              e.

```

This query will match any label path that:

- a. begins with the label `Top`
- b. and next has zero to two labels before
- c. a label beginning with the case-insensitive prefix `sport`
- d. then a label not matching `football` nor `tennis`
- e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.

- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```

Europe & Russia*@ & !Transportation

```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

**Note:** `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.15.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, there are the following specialized operators:

**Table F-11. `ltree` Operators**

Operator	Returns	Description
<code>ltree @&gt; ltree</code>	boolean	is left argument an ancestor of right (or equal)?
<code>ltree &lt;@ ltree</code>	boolean	is left argument a descendant of right (or equal)?
<code>ltree ~ lquery</code>	boolean	does <code>ltree</code> match <code>lquery</code> ?
<code>lquery ~ ltree</code>	boolean	does <code>ltree</code> match <code>lquery</code> ?
<code>ltree ? lquery[]</code>	boolean	does <code>ltree</code> match any <code>lquery</code> in array?
<code>lquery[] ? ltree</code>	boolean	does <code>ltree</code> match any <code>lquery</code> in array?
<code>ltree @ ltxtquery</code>	boolean	does <code>ltree</code> match <code>ltxtquery</code> ?
<code>ltxtquery @ ltree</code>	boolean	does <code>ltree</code> match <code>ltxtquery</code> ?
<code>ltree    ltree</code>	<code>ltree</code>	concatenate <code>ltree</code> paths
<code>ltree    text</code>	<code>ltree</code>	convert text to <code>ltree</code> and concatenate
<code>text    ltree</code>	<code>ltree</code>	convert text to <code>ltree</code> and concatenate
<code>ltree[] @&gt; ltree</code>	boolean	does array contain an ancestor of <code>ltree</code> ?
<code>ltree &lt;@ ltree[]</code>	boolean	does array contain an ancestor of <code>ltree</code> ?
<code>ltree[] &lt;@ ltree</code>	boolean	does array contain a descendant of <code>ltree</code> ?
<code>ltree @&gt; ltree[]</code>	boolean	does array contain a descendant of <code>ltree</code> ?
<code>ltree[] ~ lquery</code>	boolean	does array contain any path matching <code>lquery</code> ?
<code>lquery ~ ltree[]</code>	boolean	does array contain any path matching <code>lquery</code> ?
<code>ltree[] ? lquery[]</code>	boolean	does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>lquery[] ? ltree[]</code>	boolean	does <code>ltree</code> array contain any path matching any <code>lquery</code> ?
<code>ltree[] @ ltxtquery</code>	boolean	does array contain any path matching <code>ltxtquery</code> ?

Operator	Returns	Description
<code>ltxquery @ ltree[]</code>	boolean	does array contain any path matching <code>ltxquery</code> ?
<code>ltree[] ?@&gt; ltree</code>	ltree	first array entry that is an ancestor of <code>ltree</code> ; NULL if none
<code>ltree[] ?@&lt; ltree</code>	ltree	first array entry that is a descendant of <code>ltree</code> ; NULL if none
<code>ltree[] ?~ lquery</code>	ltree	first array entry that matches <code>lquery</code> ; NULL if none
<code>ltree[] ?@ ltxquery</code>	ltree	first array entry that matches <code>ltxquery</code> ; NULL if none

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The following functions are available:

**Table F-12. ltree Functions**

Function	Return Type	Description	Example	Result
<code>subltree(ltree, int start, int end)</code>	ltree	subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0)	<code>subltree('Top.Child1Child2', 1, 2)</code>	<code>Child1Child2</code>
<code>subpath(ltree, int offset, int len)</code>	ltree	subpath of <code>ltree</code> starting at position <code>offset</code> , length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.	<code>subpath('Top.Child1Child2', 0, 2)</code>	<code>Top..Child2</code>
<code>subpath(ltree, int offset)</code>	ltree	subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.	<code>subpath('Top.Child1Child2', 2)</code>	<code>Child1Child2</code>

Function	Return Type	Description	Example	Result
<code>nlevel(ltree)</code>	integer	number of labels in path	<code>nlevel('Top.Child1.Child2')</code>	3
<code>index(ltree a, ltree b)</code>	integer	position of first occurrence of b in a; -1 if not found	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')</code>	5
<code>index(ltree a, ltree b, int offset)</code>	integer	position of first occurrence of b in a, searching starting at offset; negative offset means start -offset labels from the end of the path	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4)</code>	5
<code>text2ltree(text)</code>	ltree	cast text to ltree		
<code>ltree2text(ltree)</code>	text	cast ltree to text		
<code>lca(ltree, ltree, ...)</code>	ltree	lowest common ancestor, i.e., longest common prefix of paths (up to 8 arguments supported)	<code>lca('1.2.2.3', '1.2.3.4.5.6')</code>	<code>1.2</code>
<code>lca(ltree[])</code>	ltree	lowest common ancestor, i.e., longest common prefix of paths	<code>lca(array['1.2.2.3'::ltree, '1.2.3'])</code>	<code>1.2</code>

### F.15.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<, <=, =, >=, >`
- GiST index over `ltree`: `<, <=, =, >=, >, @>, <@, @, ~, ?`

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

- GiST index over `ltree[]`: `ltree[] <@ ltree, ltree @> ltree[], @, ~, ?`

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Note: This index type is lossy.

### F.15.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING gist(path);
CREATE INDEX path_idx ON test USING btree(path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

We can do inheritance:

```
ltreetest=# select path from test where path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```

ltreetest=# select path from test where path ~ '*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)

ltreetest=# select path from test where path ~ '.*!pictures@.*.Astronomy.*';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)

```

Here are some examples of full text search:

```

ltreetest=# select path from test where path @ 'Astro*% & !pictures@';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)

ltreetest=# select path from test where path @ 'Astro* & !pictures@';
           path
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)

```

Path construction using functions:

```

ltreetest=# select subpath(path,0,2)||'Space' ||subpath(path,2) from test where path <@ 'Top
           ?column?
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)

```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```

CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;

ltreetest=# select ins_label(path,2,'Space') from test where path <@ 'Top.Science.Astronomy
           ins_label
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)

```

### F.15.5. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.16. oid2name

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 53.

**Note:** The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables’ filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

### F.16.1. Overview

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs. The program is controlled by a large number of command-line switches, as shown in Table F-13.

**Table F-13. oid2name switches**

Switch	Description
<code>-o oid</code>	show info for table with OID <i>oid</i>
<code>-f filenode</code>	show info for table with filenode <i>filenode</i>

Switch	Description
<code>-t tablename_pattern</code>	show info for table(s) matching <i>tablename_pattern</i>
<code>-s</code>	show tablespace OIDs
<code>-S</code>	include system objects (those in <i>information_schema</i> , <i>pg_toast</i> and <i>pg_catalog</i> schemas)
<code>-i</code>	include indexes and sequences in the listing
<code>-x</code>	display more information about each object shown: tablespace name, schema name, and OID
<code>-q</code>	omit headers (useful for scripting)
<code>-d database</code>	database to connect to
<code>-H host</code>	database server's host
<code>-p port</code>	database server's port
<code>-U username</code>	username to connect as

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a tablename (actually, it's a LIKE pattern, so you can use things like `f○○%`). You can use as many of these switches as you like, and the listing will include all objects matched by any of the switches. But note that these switches can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-S` and `-i` switches control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## F.16.2. Examples

```
$ # what's in this database server, anyway?
```

```
$ oid2name
```

```
All databases:
```

```
    Oid  Database Name  Tablespace
-----
  17228      alvherre   pg_default
  17255     regression   pg_default
  17227     template0    pg_default
      1      template1    pg_default
```

```
$ oid2name -s
```

```
All tablespaces:
```

```
    Oid  Tablespace Name
-----
   1663      pg_default
   1664      pg_global
  155151     fastdisk
  155152     bigdisk
```

```

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173

### F.16.3. Limitations

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

### F.16.4. Author

B. Palmer <bpalmer@crimelabs.net>

## F.17. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.17.1. Functions

`get_raw_page(text, int)` returns `bytea`

`get_raw_page` reads the specified block of the named table and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained.

`page_header(bytea)` returns `record`

`page_header` shows fields that are common to all PostgreSQL heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
      lsn       | tli | flags | lower | upper | special | pagesize | version | prune_xid
-----+-----+-----+-----+-----+-----+-----+-----+-----
0/24A1B50 |   1 |      1 |   232 |   368 |       8192 |   8192 |         4 |         0
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

`heap_page_items(bytea)` returns `setof record`

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup.h` for explanations of the fields returned.

`bt_metap(text)` returns record

`bt_metap` returns information about a btree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----
magic      | 340322
version    | 2
root       | 1
level      | 0
fastroot   | 1
fastlevel  | 0
```

`bt_page_stats(text, int)` returns record

`bt_page_stats` returns summary information about single pages of btree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]+-----
blkno      | 1
type       | 1
live_items | 256
dead_items | 0
avg_item_size | 12
page_size  | 8192
free_size  | 4056
btpo_prev  | 0
btpo_next  | 0
btpo       | 0
btpo_flags | 3
```

`bt_page_items(text, int)` returns setof record

`bt_page_items` returns detailed information about all of the items on a btree index page. For example:

```
test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
 itemoffset | ctid  | itemlen | nulls | vars | data
-----+-----+-----+-----+-----+-----
          1 | (0,1) |      12 | f     | f    | 23 27 00 00
          2 | (0,2) |      12 | f     | f    | 24 27 00 00
          3 | (0,3) |      12 | f     | f    | 25 27 00 00
          4 | (0,4) |      12 | f     | f    | 26 27 00 00
          5 | (0,5) |      12 | f     | f    | 27 27 00 00
          6 | (0,6) |      12 | f     | f    | 28 27 00 00
          7 | (0,7) |      12 | f     | f    | 29 27 00 00
          8 | (0,8) |      12 | f     | f    | 2a 27 00 00
```

## F.18. pgbench

pgbench is a simple program for running benchmark tests on PostgreSQL. It runs the same sequence of SQL commands over and over, possibly in multiple concurrent database sessions, and then calculates the average transaction rate (transactions per second). By default, pgbench tests a scenario that is loosely based on TPC-B, involving five `SELECT`, `UPDATE`, and `INSERT` commands per transaction. However, it is easy to test other cases by writing your own transaction script files.

Typical output from pgbench looks like:

```
transaction type: TPC-B (sort of)
scaling factor: 10
number of clients: 10
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
tps = 85.184871 (including connections establishing)
tps = 85.296346 (excluding connections establishing)
```

The first four lines just report some of the most important parameter settings. The next line reports the number of transactions completed and intended (the latter being just the product of number of clients and number of transactions); these will be equal unless the run failed before completion. The last two lines report the TPS rate, figured with and without counting the time to start database sessions.

### F.18.1. Overview

The default TPC-B-like transaction test requires specific tables to be set up beforehand. pgbench should be invoked with the `-i` (initialize) option to create and populate these tables. (When you are testing a custom script, you don't need this step, but will instead need to do whatever setup your test needs.) Initialization looks like:

```
pgbench -i [ other-options ] dbname
```

where *dbname* is the name of the already-created database to test in. (You may also need `-h`, `-p`, and/or `-U` options to specify how to connect to the database server.)

#### Caution

pgbench -i creates four tables `accounts`, `branches`, `history`, and `tellers`, destroying any existing tables of these names. Be very careful to use another database if you have tables having these names!

At the default “scale factor” of 1, the tables initially contain this many rows:

table	# of rows
branches	1
tellers	10
accounts	100000
history	0

You can (and, for most purposes, probably should) increase the number of rows by using the `-s` (scale factor) option. The `-F` (fillfactor) option might also be used at this point.

Once you have done the necessary setup, you can run your benchmark with a command that doesn't include `-i`, that is

```
pgbench [ options ] dbname
```

In nearly all cases, you'll need some options to make a useful test. The most important options are `-c` (number of clients), `-t` (number of transactions), and `-f` (specify a custom script file). See below for a full list.

Table F-14 shows options that are used during database initialization, while Table F-15 shows options that are used while running benchmarks, and Table F-16 shows options that are useful in both cases.

**Table F-14. pgbench initialization options**

Option	Description
<code>-i</code>	Required to invoke initialization mode.
<code>-s scale_factor</code>	Multiply the number of rows generated by the scale factor. For example, <code>-s 100</code> will imply 10,000,000 rows in the <code>accounts</code> table. Default is 1.
<code>-F fillfactor</code>	Create the <code>accounts</code> , <code>tellers</code> and <code>branches</code> tables with the given fillfactor. Default is 100.

**Table F-15. pgbench benchmarking options**

Option	Description
<code>-c clients</code>	Number of clients simulated, that is, number of concurrent database sessions. Default is 1.
<code>-t transactions</code>	Number of transactions each client runs. Default is 10.
<code>-N</code>	Do not update <code>tellers</code> and <code>branches</code> . This will avoid update contention on these tables, but it makes the test case even less like TPC-B.
<code>-S</code>	Perform select-only transactions instead of TPC-B-like test.
<code>-f filename</code>	Read transaction script from <code>filename</code> . See below for details. <code>-N</code> , <code>-S</code> , and <code>-f</code> are mutually exclusive.

Option	Description
<code>-n</code>	No vacuuming is performed before running the test. This option is <i>necessary</i> if you are running a custom test scenario that does not include the standard tables <code>accounts</code> , <code>branches</code> , <code>history</code> , and <code>tellers</code> .
<code>-v</code>	Vacuum all four standard tables before running the test. With neither <code>-n</code> nor <code>-v</code> , <code>pgbench</code> will vacuum <code>tellers</code> and <code>branches</code> tables, and will remove all entries in <code>history</code> .
<code>-D varname=value</code>	Define a variable for use by a custom script (see below). Multiple <code>-D</code> options are allowed.
<code>-C</code>	Establish a new connection for each transaction, rather than doing it just once per client thread. This is useful to measure the connection overhead.
<code>-l</code>	Write the time taken by each transaction to a logfile. See below for details.
<code>-s scale_factor</code>	Report the specified scale factor in <code>pgbench</code> 's output. With the built-in tests, this is not necessary; the correct scale factor will be detected by counting the number of rows in the <code>branches</code> table. However, when testing custom benchmarks ( <code>-f</code> option), the scale factor will be reported as 1 unless this option is used.
<code>-d</code>	Print debugging output.

Table F-16. `pgbench` common options

Option	Description
<code>-h hostname</code>	database server's host
<code>-p port</code>	database server's port
<code>-U login</code>	username to connect as

## F.18.2. What is the “transaction” actually performed in `pgbench`?

The default transaction script issues seven commands per transaction:

1. `BEGIN;`
2. `UPDATE accounts SET abalance = abalance + :delta WHERE aid = :aid;`
3. `SELECT abalance FROM accounts WHERE aid = :aid;`
4. `UPDATE tellers SET tbalance = tbalance + :delta WHERE tid = :tid;`

```

5. UPDATE branches SET bbalance = bbalance + :delta WHERE bid = :bid;
6. INSERT INTO history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid,
   :aid, :delta, CURRENT_TIMESTAMP);
7. END;

```

If you specify `-N`, steps 4 and 5 aren't included in the transaction. If you specify `-S`, only the `SELECT` is issued.

### F.18.3. Custom Scripts

`pgbench` has support for running custom benchmark scenarios by replacing the default transaction script (described above) with a transaction script read from a file (`-f` option). In this case a “transaction” counts as one execution of a script file. You can even specify multiple scripts (multiple `-f` options), in which case a random one of the scripts is chosen each time a client session starts a new transaction.

The format of a script file is one SQL command per line; multi-line SQL commands are not supported. Empty lines and lines beginning with `--` are ignored. Script file lines can also be “meta commands”, which are interpreted by `pgbench` itself, as described below.

There is a simple variable-substitution facility for script files. Variables can be set by the command-line `-D` option, explained above, or by the meta commands explained below. In addition to any variables preset by `-D` command-line options, the variable `scale` is preset to the current scale factor. Once set, a variable's value can be inserted into a SQL command by writing `:variablename`. When running more than one client session, each session has its own set of variables.

Script file meta commands begin with a backslash (`\`). Arguments to a meta command are separated by white space. These meta commands are supported:

```
\set varname operand1 [ operator operand2 ]
```

Sets variable `varname` to a calculated integer value. Each `operand` is either an integer constant or a `:variablename` reference to a variable having an integer value. The `operator` can be `+`, `-`, `*`, or `/`.

Example:

```
\set ntellers 10 * :scale
```

```
\setrandom varname min max
```

Sets variable `varname` to a random integer value between the limits `min` and `max`. Each limit can be either an integer constant or a `:variablename` reference to a variable having an integer value.

Example:

```
\setrandom aid 1 :naccounts
```

```
\sleep number [ us | ms | s ]
```

Causes script execution to sleep for the specified duration in microseconds (`us`), milliseconds (`ms`) or seconds (`s`). If the unit is omitted then seconds are the default. `number` can be either an integer constant or a `:variablename` reference to a variable having an integer value.

Example:

```
\sleep 10 ms
```

As an example, the full definition of the built-in TPC-B-like transaction is:

```
\set nbranches :scale
\set ntellers 10 * :scale
\set naccounts 100000 * :scale
\setrandom aid 1 :naccounts
\setrandom bid 1 :nbranches
\setrandom tid 1 :ntellers
\setrandom delta -5000 5000
BEGIN;
UPDATE accounts SET abalance = abalance + :delta WHERE aid = :aid;
SELECT abalance FROM accounts WHERE aid = :aid;
UPDATE tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
UPDATE branches SET bbalance = bbalance + :delta WHERE bid = :bid;
INSERT INTO history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
END;
```

This script allows each iteration of the transaction to reference different, randomly-chosen rows. (This example also shows why it's important for each client session to have its own variables — otherwise they'd not be independently touching different rows.)

### F.18.4. Per-transaction logging

With the `-l` option, `pgbench` writes the time taken by each transaction to a logfile. The logfile will be named `pgbench_log.nnn`, where `nnn` is the PID of the `pgbench` process. The format of the log is:

```
client_id transaction_no time file_no time_epoch time_us
```

where `time` is the elapsed transaction time in microseconds, `file_no` identifies which script file was used (useful when multiple scripts were specified with `-f`), and `time_epoch/time_us` are a UNIX epoch format timestamp and an offset in microseconds (suitable for creating a ISO 8601 timestamp with fractional seconds) showing when the transaction completed.

Here are example outputs:

```
0 199 2241 0 1175850568 995598
0 200 2465 0 1175850568 998079
0 201 2513 0 1175850569 608
0 202 2038 0 1175850569 2663
```

## F.18.5. Good Practices

It is very easy to use `pgbench` to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, *never* believe any test that runs for only a few seconds. Increase the `-t` setting enough to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It's a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (`-s`) should be at least as large as the largest number of clients you intend to test (`-c`); else you'll mostly be measuring update contention. There are only `-s` rows in the `branches` table, and every transaction wants to update one of them, so `-c` values in excess of `-s` will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it's been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of `pgbench` is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running `pgbench` on a different machine from the database server, although low network latency will be essential. It might even be useful to run several `pgbench` instances concurrently, on several client machines, against the same database server.

## F.19. `pg_buffercache`

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default public access is revoked from both of these, just in case there are security issues lurking.

### F.19.1. The `pg_buffercache` view

The definitions of the columns exposed by the view are:

**Table F-17. `pg_buffercache` Columns**

Name	Type	References	Description
<code>bufferid</code>	integer		ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode</code>	oid	<code>pg_class.relfilenode</code>	Relfilenode of the relation
<code>reltablespace</code>	oid	<code>pg_tablespace.oid</code>	Tablespace OID of the relation

Name	Type	References	Description
reldatabase	oid	pg_database.oid	Database OID of the relation
relblocknumber	bigint		Page number within the relation
isdirty	boolean		Is the page dirty?
usagecount	smallint		Page LRU count

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

When the `pg_buffercache` view is accessed, internal buffer manager locks are taken for long enough to copy all the buffer state data that the view will display. This ensures that the view produces a consistent set of results, while not blocking normal buffer activity longer than necessary. Nonetheless there could be some impact on database performance if this view is read often.

## F.19.2. Sample output

```

regression=# SELECT c.relname, count(*) AS buffers
              FROM pg_buffercache b INNER JOIN pg_class c
              ON b.relfilenode = c.relfilenode AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              GROUP BY c.relname
              ORDER BY 2 DESC LIMIT 10;
 relname                | buffers
-----+-----
tenk2                   |    345
tenk1                   |    141
pg_proc                 |     46
pg_class                |     45
pg_attribute            |     43
pg_class_relname_nsp_index |     30
pg_proc_proname_args_nsp_index |     28
pg_attribute_relid_attnam_index |     26
pg_depend               |     22
pg_depend_reference_index |     20
(10 rows)

```

## F.20. pgcrypto

The `pgcrypto` module provides cryptographic functions for PostgreSQL.

### F.20.1. General hashing functions

#### F.20.1.1. `digest()`

```
digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea
```

Computes a binary hash of the given data. `type` is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in Table F-21.

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

#### F.20.1.2. `hmac()`

```
hmac(data text, key text, type text) returns bytea
hmac(data bytea, key text, type text) returns bytea
```

Calculates hashed MAC for data with key `key`. `type` is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

## F.20.2. Password hashing functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from usual hashing algorithms like MD5 or SHA1 in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

**Table F-18. Supported algorithms for `crypt()`**

Algorithm	Max password length	Adaptive?	Salt bits	Description
bf	72	yes	128	Blowfish-based, variant 2a
md5	unlimited	no	48	MD5-based crypt
xdes	8	yes	24	Extended DES
des	8	no	12	Original UNIX crypt

### F.20.2.1. `crypt()`

`crypt(password text, salt text) returns text`

Calculates a `crypt(3)`-style hash of `password`. When storing a new password, you need to use `gen_salt()` to generate a new `salt` value. To check a password, pass the stored hash value as `salt`, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT pswhash = crypt('entered password', pswhash) FROM ... ;
```

This returns `true` if the entered password is correct.

**F.20.2.2. `gen_salt()`**

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The `type` parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The `iter_count` parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm:

**Table F-19. Iteration counts for `crypt()`**

Algorithm	Default	Min	Max
<code>xdes</code>	725	1	16777215
<code>bf</code>	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES `crypt` was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Here is a table that gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lowercase letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

**Table F-20. Hash algorithm speeds**

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]
<code>crypt-bf/8</code>	28	246 years	251322 years
<code>crypt-bf/7</code>	57	121 years	123457 years
<code>crypt-bf/6</code>	112	62 years	62831 years
<code>crypt-bf/5</code>	211	33 years	33351 years
<code>crypt-md5</code>	2681	2.6 years	2625 years
<code>crypt-des</code>	362837	7 days	19 years
<code>sha1</code>	590223	4 days	12 years
<code>md5</code>	2345086	1 day	3 years

Notes:

- The machine used is a 1.5GHz Pentium 4.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.

- `md5` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 213 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.20.3. PGP encryption functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

**F.20.3.1. `pgp_sym_encrypt()`**

```
pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea
```

Encrypt data with a symmetric PGP key `psw`. The `options` parameter can contain option settings, as described below.

**F.20.3.2. `pgp_sym_decrypt()`**

```
pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea
```

Decrypt a symmetric-key-encrypted PGP message.

Decrypting bytea data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

**F.20.3.3. `pgp_pub_encrypt()`**

```
pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea
```

Encrypt data with a public PGP key `key`. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

**F.20.3.4. `pgp_pub_decrypt()`**

```
pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea
```

Decrypt a public-key-encrypted message. `key` must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in `psw`. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting bytea data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

**F.20.3.5. `pgp_key_id()`**

```
pgp_key_id(bytea) returns text
```

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

**F.20.3.6. `armor()`, `dearmor()`**

```
armor(data bytea) returns text
dearmor(data text) returns bytea
```

These functions wrap/unwrap binary data into PGP Ascii Armor format, which is basically Base64 with CRC and additional formatting.

**F.20.3.7. Options for PGP functions**

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

**F.20.3.7.1. *cipher-algo***

Which cipher algorithm to use.

```
Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt
```

*F.20.3.7.2. compress-algo*

Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:  
 0 - no compression  
 1 - ZIP compression  
 2 - ZLIB compression (= ZIP plus meta-data and block CRCs)  
 Default: 0  
 Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

*F.20.3.7.3. compress-level*

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9  
 Default: 6  
 Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

*F.20.3.7.4. convert-crlf*

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1  
 Default: 0  
 Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

*F.20.3.7.5. disable-mdc*

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1  
 Default: 0  
 Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

*F.20.3.7.6. enable-session-key*

Use separate session key. Public-key encryption always uses a separate session key; this is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1  
 Default: 0

Applies to: `pgp_sym_encrypt`

#### *F.20.3.7.7. s2k-mode*

Which S2K algorithm to use.

Values:  
0 - Without salt. Dangerous!  
1 - With salt but with fixed iteration count.  
3 - Variable iteration count.  
Default: 3  
Applies to: `pgp_sym_encrypt`

#### *F.20.3.7.8. s2k-digest-algo*

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`  
Default: `sha1`  
Applies to: `pgp_sym_encrypt`

#### *F.20.3.7.9. s2k-cipher-algo*

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`  
Default: `use cipher-algo`  
Applies to: `pgp_sym_encrypt`

#### *F.20.3.7.10. unicode-mode*

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1  
Default: 0  
Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

### F.20.3.8. Generating PGP keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ascii-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ascii-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, The GNU Privacy Handbook<sup>2</sup> and other documentation on <http://www.gnupg.org>.

### F.20.3.9. Limitations of PGP code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

## F.20.4. Raw encryption functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

---

2. <http://www.gnupg.org/gph/en/manual.html>

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea

encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by `type`. The syntax of the `type` string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128)

and *mode* is one of:

- `cbc` — next block depends on previous (default)
- `ecb` — each block is encrypted separately (for testing only)

and *padding* is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

## F.20.5. Random-data functions

```
gen_random_bytes(count integer) returns bytea
```

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

## F.20.6. Notes

### F.20.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main PostgreSQL `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

**Table F-21. Summary of functionality with and without `OpenSSL`**

Functionality	Built-in	With <code>OpenSSL</code>
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes (Note 1)
Other digest algorithms	no	yes (Note 2)
Blowfish	yes	yes
AES	yes	yes (Note 3)
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

Notes:

1. SHA2 algorithms were added to `OpenSSL` in version 0.9.8. For older versions, `pgcrypto` will use built-in code.
2. Any digest algorithm `OpenSSL` supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
3. AES is included in `OpenSSL` since version 0.9.7. For older versions, `pgcrypto` will use built-in code.

### F.20.6.2. NULL handling

As is standard in SQL, all functions return `NULL`, if any of the arguments are `NULL`. This may create security risks on careless usage.

### F.20.6.3. Security limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

### F.20.6.4. Useful reading

## F.20.7. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

**Table F-22. Credits**

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com
Blowfish cipher	Simon Tatham	PuTTY
Rijndael cipher	Brian Gladman	OpenBSD sys/crypto
MD5 and SHA1	WIDE Project	KAME kame/sys/crypto
SHA256/384/512	Aaron D. Gifford	OpenBSD sys/crypto
BIGNUM math	Michael J. Fromberger	dartmouth.edu/~sting/sw/imath

## F.21. `pg_freespacemap`

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides two C functions: `pg_freespacemap_relations` and `pg_freespacemap_pages` that each return a set of records, plus two views `pg_freespacemap_relations` and `pg_freespacemap_pages` that wrap the functions for convenient use.

By default public access is revoked from the functions and views, just in case there are security issues lurking.

### F.21.1. The `pg_freespacemap` views

The definitions of the columns exposed by the views are:

**Table F-23. `pg_freespacemap_relations` Columns**

Name	Type	References	Description
------	------	------------	-------------

Name	Type	References	Description
reltablespace	oid	pg_tablespace.oid	Tablespace OID of the relation
reldatabase	oid	pg_database.oid	Database OID of the relation
relfilenode	oid	pg_class.relfilenode	Relfilenode of the relation
avgrequest	integer		Moving average of free space requests (NULL for indexes)
interestingpages	integer		Count of pages last reported as containing useful free space
storedpages	integer		Count of pages actually stored in free space map
nextpage	integer		Page index (from 0) to start next search at

**Table F-24. pg\_freespacemap\_pages Columns**

Name	Type	References	Description
reltablespace	oid	pg_tablespace.oid	Tablespace OID of the relation
reldatabase	oid	pg_database.oid	Database OID of the relation
relfilenode	oid	pg_class.relfilenode	Relfilenode of the relation
relblocknumber	bigint		Page number within the relation
bytes	integer		Free bytes in the page, or NULL for an index page (see below)

For `pg_freespacemap_relations`, there is one row for each relation in the free space map. `storedpages` is the number of pages actually stored in the map, while `interestingpages` is the number of pages the last `VACUUM` thought had useful amounts of free space.

If `storedpages` is consistently less than `interestingpages` then it'd be a good idea to increase `max_fsm_pages`. Also, if the number of rows in `pg_freespacemap_relations` is close to `max_fsm_relations`, then you should consider increasing `max_fsm_relations`.

For `pg_freespacemap_pages`, there is one row for each page in the free space map. The number of rows for a relation will match the `storedpages` column in `pg_freespacemap_relations`.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the average request size and free bytes within a page are not meaningful, and are shown as NULL.

Because the map is shared by all the databases, there will normally be entries for relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

When either of the views is accessed, internal free space map locks are taken for long enough to copy all the state data that the view will display. This ensures that the views produce a consistent set of results, while not blocking normal activity longer than necessary. Nonetheless there could be some impact on database performance if they are read often.

## F.21.2. Sample output

```
regression=# SELECT c.relname, r.avgrequest, r.interestingpages, r.storedpages
              FROM pg_freespacemap_relations r INNER JOIN pg_class c
              ON r.relfilenode = c.relfilenode AND
                 r.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              ORDER BY r.storedpages DESC LIMIT 10;
```

relname	avgrequest	interestingpages	storedpages
onek	256	109	109
pg_attribute	167	93	93
pg_class	191	49	49
pg_attribute_relid_attnam_index		48	48
onek2	256	37	37

### F.21.3. Author

Mark Kirkwood <markir@paradise.net.nz>

## F.22. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

### F.22.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are:

**Table F-25. `pgrowlocks` output columns**

Name	Type	Description
<code>locked_row</code>	<code>tid</code>	Tuple ID (TID) of locked row
<code>lock_type</code>	<code>text</code>	Shared for shared lock, or Exclusive for exclusive lock
<code>locker</code>	<code>xid</code>	Transaction ID of locker, or multixact ID if multi-transaction
<code>multi</code>	<code>boolean</code>	True if locker is a multi-transaction
<code>xids</code>	<code>xid[]</code>	Transaction IDs of lockers (more than one if multi-transaction)
<code>pids</code>	<code>integer[]</code>	Process IDs of locking backends (more than one if multi-transaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If the table as a whole is exclusive-locked by someone else, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that (as of PostgreSQL 8.3) such a query will be very inefficient.

## F.22.2. Sample output

```
test=# SELECT * FROM pgrowlocks('t1');
 locked_row | lock_type | locker | multi | xids | pids
-----+-----+-----+-----+-----+-----
      (0,1) | Shared   |      19 | t     | {804,805} | {29066,29068}
      (0,2) | Shared   |      19 | t     | {804,805} | {29066,29068}
      (0,3) | Exclusive |     804 | f     | {804}      | {29066}
      (0,4) | Exclusive |     804 | f     | {804}      | {29066}
(4 rows)
```

## F.22.3. Author

Tatsuo Ishii

# F.23. pg\_standby

`pg_standby` supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

`pg_standby` is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see Section 24.4).

`pg_standby` features include:

- Supports copy or link for restoring WAL files
- Written in C, so very portable and easy to install
- Easy-to-modify source code, with specifically designated sections to modify for your own needs
- Already tested on Linux and Windows

## F.23.1. Usage

To configure a standby server to use `pg_standby`, put this into its `recovery.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where *archiveDir* is the directory from which WAL segment files should be restored.

The full syntax of `pg_standby`'s command line is

```
pg_standby [ option ... ] archivelocation nextwalfile xlogfilepath [ restartwalfile ]
```

When used within `restore_command`, the `%f` and `%p` macros should be specified for *nextwalfile* and *xlogfilepath* respectively, to provide the actual file and path required for the restore.

If *restartwalfile* is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area.

`pg_standby` assumes that *archivelocation* is a directory readable by the server-owning user. If *restartwalfile* (or `-k`) is specified, the *archivelocation* directory must be writable too.

**Table F-26. `pg_standby` options**

Option	Default	Description
<code>-c</code>	yes	Use <code>cp</code> or <code>copy</code> command to restore WAL files from archive.
<code>-d</code>	no	Print lots of debug logging output on <code>stderr</code> .
<code>-k numfiles</code>	0	Remove files from <i>archivelocation</i> so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from <i>archivelocation</i> . This parameter will be silently ignored if <i>restartwalfile</i> is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is <i>deprecated</i> as of PostgreSQL 8.3; it is safer and more efficient to specify a <i>restartwalfile</i> parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

Option	Default	Description
<code>-l</code>	no	Use <code>ln</code> command to restore WAL files from archive. Link is more efficient than copy, but the default is copy since link will not work in all scenarios. On Windows, this option uses the <code>mklink</code> command to provide a file-to-file symbolic link. <code>-l</code> will not work on versions of Windows prior to Vista.
<code>-r maxretries</code>	3	Set the maximum number of times to retry the copy or link command if it fails. After each failure, we wait for <code>sleeptime * num_retries</code> so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.
<code>-s sleeptime</code>	5	Set the number of seconds (up to 60) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult Section 24.4 for discussion.
<code>-t triggerfile</code>	none	Specify a trigger file whose presence should cause recovery to end whether or not the next WAL file is available. It is recommended that you use a structured filename to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example <code>/tmp/pgsql.trigger.5432.</code>

Option	Default	Description
<code>-w maxwaittime</code>	0	Set the maximum number of seconds to wait for the next WAL file, after which recovery will end and the standby will come up. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult Section 24.4 for discussion.

**Note:** `--help` is not supported since `pg_standby` is not intended for interactive use, except during development and testing.

## F.23.2. Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p .../archive/%f'
```

```
restore_command = 'pg_standby -l -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f %p %r 2>
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- use the `ln` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'
```

```
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\\archive %f %p %r 2>>stan
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`

- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears
- remove no-longer-needed files from the archive directory

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

### F.23.3. Supported server versions

`pg_standby` is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the `%r` macro, which is designed to let `pg_standby` know the last file it needs to keep. With PostgreSQL 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

## F.24. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

### F.24.1. Functions

`pgstattuple(text)` returns record

`pgstattuple` returns a relation's physical length, percentage of "dead" tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified). For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95
```

The output columns are:

**Table F-27. pgstattuple output columns**

Column	Type	Description
table_len	bigint	Physical relation length in bytes
tuple_count	bigint	Number of live tuples
tuple_len	bigint	Total length of live tuples in bytes
tuple_percent	float8	Percentage of live tuples
dead_tuple_count	bigint	Number of dead tuples
dead_tuple_len	bigint	Total length of dead tuples in bytes
dead_tuple_percent	float8	Percentage of dead tuples
free_space	bigint	Total free space in bytes
free_percent	float8	Percentage of free space

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

pgstattuple judges a tuple is “dead” if HeapTupleSatisfiesNow returns false.

pgstattuple(oid) returns record

This is the same as pgstattuple(text), except that the target relation is specified by OID.

pgstatindex(text) returns record

pgstatindex returns a record showing information about a btree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version          | 2
tree_level       | 0
index_size       | 8192
root_block_no    | 1
internal_pages   | 0
leaf_pages       | 1
empty_pages      | 0
deleted_pages    | 0
avg_leaf_density | 50.27
leaf_fragmentation | 0
```

The output columns are:

**Table F-28. pgstatindex output columns**

Column	Type	Description
version	integer	Btree version number
tree_level	integer	Tree level of the root page
index_size	integer	Total number of pages in index

Column	Type	Description
root_block_no	integer	Location of root block
internal_pages	integer	Number of “internal” (upper-level) pages
leaf_pages	integer	Number of leaf pages
empty_pages	integer	Number of empty pages
deleted_pages	integer	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pg_relpages(text)` returns integer

`pg_relpages` returns the number of pages in the relation.

## F.25. `pg_trgm`

The `pg_trgm` module provides functions and operators for determining the similarity of text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

### F.25.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

**Note:** A string is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”.

### F.25.2. Functions and Operators

Table F-29. `pg_trgm` functions

Function	Returns	Description
<code>similarity(text, text)</code>	<code>real</code>	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm(text)</code>	<code>text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>show_limit()</code>	<code>real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example.
<code>set_limit(real)</code>	<code>real</code>	Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in.

Table F-30. `pg_trgm` operators

Operator	Returns	Description
<code>text % text</code>	<code>boolean</code>	Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>set_limit</code> .

### F.25.3. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the `%` similarity operator (and no other operators, so you may want a regular btree index too).

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING gist (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING gin (t gin_trgm_ops);
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.

## F.25.4. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector("simple", bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING gin(word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note:** Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.26. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

### F.26.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval

contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
           pH
-----
6.25 .. 6.50
(1 row)
```

## F.26.2. Syntax

The external representation of an interval is formed using one or two floating point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` and `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.)

In the following table,  $x$ ,  $y$ , and  $\delta$  denote floating-point numbers.  $x$  and  $y$ , but not  $\delta$ , can be preceded by a certainty indicator:

**Table F-31. `seg` external representations**

$x$	Single value (zero-length interval)
$x .. y$	Interval from $x$ to $y$
$x (+-) \delta$	Interval from $x - \delta$ to $x + \delta$
$x ..$	Open interval with lower bound $x$
$.. x$	Open interval with upper bound $x$

**Table F-32. Examples of valid `seg` input**

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records <code>~</code> in the data. <code>~</code> is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. <code>&lt;</code> is ignored but is preserved as a comment.
>5.0	Creates a point at 5.0. <code>&gt;</code> is ignored but is preserved as a comment.

<code>5 (+-) 0.3</code>	Creates an interval <code>4.7 .. 5.3</code> . Note that the <code>(+-)</code> notation isn't preserved.
<code>50 ..</code>	Everything that is greater than or equal to 50
<code>.. 0</code>	Everything that is less than or equal to 0
<code>1.5e-2 .. 2E-2</code>	Creates an interval <code>0.015 .. 0.02</code>
<code>1 ... 2</code>	The same as <code>1...2</code> , or <code>1 .. 2</code> , or <code>1..2</code> (spaces around the range operator are ignored)

Because `...` is widely used in data sources, it is allowed as an alternative spelling of `..`. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be `23` or `0.23`. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

### F.26.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns `0.00`, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value `0.0067` is considered to have just 2 significant digits.

### F.26.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST opclass include:

- `[a, b] << [c, d]`                      Is left of  
`[a, b]` is entirely to the left of `[c, d]`. That is, `[a, b] << [c, d]` is true if `b < c` and false otherwise
- `[a, b] >> [c, d]`                      Is right of  
`[a, b]` is entirely to the right of `[c, d]`. That is, `[a, b] >> [c, d]` is true if `a > d` and false otherwise
- `[a, b] &< [c, d]`                      Overlaps or is left of  
This might be better read as “does not extend to right of”. It is true when `b <= d`.
- `[a, b] &> [c, d]`                      Overlaps or is right of  
This might be better read as “does not extend to left of”. It is true when `a >= c`.
- `[a, b] = [c, d]`                      Same as  
The segments `[a, b]` and `[c, d]` are identical, that is, `a = c` and `b = d`
- `[a, b] && [c, d]`                      Overlaps  
The segments `[a, b]` and `[c, d]` overlap.

- `[a, b] @> [c, d]`                      Contains

The segment `[a, b]` contains the segment `[c, d]`, that is, `a <= c` and `b >= d`

- `[a, b] <@ [c, d]`                      Contained in

The segment `[a, b]` is contained in `[c, d]`, that is, `a >= c` and `b <= d`

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric datatypes!)

The standard B-tree operators are also provided, for example

```
[a, b] < [c, d]                      Less than
[a, b] > [c, d]                      Greater than
```

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.26.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11                      -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.26.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<http://db.cs.berkeley.edu/~jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.27. spi

The `contrib/spi` module provides several workable examples of using SPI and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

### F.27.1. refint.c — functions for implementing referential integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

### F.27.2. timetravel.c — functions for implementing time travel

Long ago, PostgreSQL had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of `abstime` type to store the date when a tuple was inserted (`start_date`) and changed/deleted (`stop_date`):

```
CREATE TABLE mytab (
    ...
    start_date    abstime,
    stop_date     abstime
    ...
);
```

The columns can be named whatever you like, but in this discussion we'll call them `start_date` and `stop_date`.

When a new row is inserted, `start_date` should normally be set to current time, and `stop_date` to `infinity`. The trigger will automatically substitute these values if the inserted data contains nulls in these columns.

Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with `stop_date` equal to `infinity` are “valid now”, and can be modified. Tuples with a finite `stop_date` cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the `stop_date` in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. `Start_date` in this new tuple will be set to current time and `stop_date` to `infinity`.

A delete does not actually remove the tuple but only sets its `stop_date` to current time.

To query for tuples “valid now”, include `stop_date = 'infinity'` in the query’s `WHERE` condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on `start_date` and `stop_date`.

`timetravel()` is the general trigger function that supports this behavior. Create a `BEFORE INSERT OR UPDATE OR DELETE` trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the `start_date` and `stop_date` columns. Optionally, you can specify one to three more arguments, which must refer to columns of type `text`. The trigger will store the name of the current user into the first of these columns during `INSERT`, the second column during `UPDATE`, and the third during `DELETE`.

`set_timetravel()` allows you to turn time-travel on or off for a table. `set_timetravel('mytab', 1)` will turn TT ON for table `mytab`. `set_timetravel('mytab', 0)` will turn TT OFF for table `mytab`. In both cases the old status is reported. While TT is off, you can modify the `start_date` and `stop_date` columns freely. Note that the on/off status is local to the current database session — fresh sessions will always start out with TT ON for all tables.

`get_timetravel()` returns the TT state for a table without changing it.

There is an example in `timetravel.example`.

### F.27.3. `autoinc.c` — functions for autoincrementing fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

### F.27.4. `insert_username.c` — functions for tracking who changed a table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

### F.27.5. `moddatetime.c` — functions for tracking last modification time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the `timestamp` column to be modified.

There is an example in `moddatetime.example`.

## F.28. `sslinfo`

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return `NULL`) if the current connection does not use SSL.

This extension won't build at all unless the installation was configured with `--with-openssl`.

### F.28.1. Functions Provided

`ssl_is_used()` returns `boolean`

Returns `TRUE` if current connection to server uses SSL, and `FALSE` otherwise.

`ssl_client_cert_present()` returns `boolean`

Returns `TRUE` if current client has presented a valid SSL client certificate to the server, and `FALSE` otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns `numeric`

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change his keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL\_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's `root.crt` file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

## F.28.2. Author

Victor Wagner <vitus@cryptocom.ru>, Cryptocom LTD

E-Mail of Cryptocom OpenSSL development group: <openssl@cryptocom.ru>

## F.29. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

### F.29.1. Functions Provided

**Table F-33.** `tablefunc` functions

Function	Returns	Description
<code>normal_rand(int numvals, float8 mean, float8 stddev)</code>	setof float8	Produces a set of normally distributed random values
<code>crosstab(text sql)</code>	setof record	Produces a “pivot table” containing row names plus $N$ value columns, where $N$ is determined by the rowtype specified in the calling query
<code>crosstabN(text sql)</code>	setof table_crosstab_N	Produces a “pivot table” containing row names plus $N$ value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below
<code>crosstab(text source_sql, text category_sql)</code>	setof record	Produces a “pivot table” with the value columns specified by a second query
<code>crosstab(text sql, int N)</code>	setof record	Obsolete version of <code>crosstab(text)</code> . The parameter $N$ is now ignored, since the number of value columns is always determined by the calling query

Function	Returns	Description
<code>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])</code>	setof record	Produces a representation of a hierarchical tree structure

**F.29.1.1. normal\_rand**

`normal_rand(int numvals, float8 mean, float8 stddev)` returns setof float8

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

`numvals` is the number of values to be returned from the function. `mean` is the mean of the normal distribution of values and `stddev` is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
       normal_rand
-----
 1.56556322244898
 9.10040991424657
 5.36957140345079
-0.369151492880995
 0.283600703686639
.
.
.
 4.82992125404908
 9.71308014517282
 2.49639286969028
(1000 rows)
```

**F.29.1.2. crosstab(text)**

`crosstab(text sql)`  
`crosstab(text sql, int N)`

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
```

```
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

	<== value columns ==>	
row_name	category_1	category_2
row1	val1	val2
row2	val5	val6

The `FROM` clause must define the output as one `row_name` column (of the same datatype as the first result column of the SQL query) followed by `N` `value` columns (all of the same datatype as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output value columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output value columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1, 2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
    'select rowid, attribute, value
     from ct
     where attribute = "att2" or attribute = "att3"
     order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

row_name	category_1	category_2	category_3
test1	val2	val3	
test2	val6	val7	

(2 rows)

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

### F.29.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output rowtypes are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
```

```

category_1 TEXT,
category_2 TEXT,
    .
    .
    .
category_N TEXT
);

```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```

SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = "att2" or attribute = "att3"
    order by 1,2');

```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in the installation script. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```

CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
RETURNS setof my_crosstab_float8_5_cols
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,

```

```

    OUT my_category_5 float8)
  RETURNS setof record
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

#### F.29.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

```

cat
-----
cat1
cat2
cat3
cat4

```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
  AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

		<==	value	columns	==>
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are  $N$  columns in the `source_sql` query's result, the first  $N-2$  of them must match up with the first  $N-2$  output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any "extra" columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching category values. If a row's category does not match any output of the `category_sql` query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
```

```

"Oct" int,
"Nov" int,
"Dec" int
);
year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
2007 | 1000 | 1500 |      |      |      |      | 500 |      |      |      | 1500 | 2000
2008 | 1000 |      |      |      |      |      |      |      |      |      |      |
(2 rows)

```

```

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

```

```

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)

```

AS

```

(
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
);
rowid |          rowdt          | temperature | test_result |          test_startdate          |
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS       |                               |
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL       | Sat Mar 01 00:00:00 2003 |
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

### F.29.1.5. connectby

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

**Table F-34. `connectby` parameters**

Parameter	Description
<code>relname</code>	Name of the source relation
<code>keyid_fld</code>	Name of the key field
<code>parent_keyid_fld</code>	Name of the parent-key field
<code>orderby_fld</code>	Name of the field to order siblings by (optional)
<code>start_with</code>	Key value of the row to start at
<code>max_depth</code>	Maximum depth to descend to, or zero for unlimited depth
<code>branch_delim</code>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the `start_with` value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~
    AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```

CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
  AS t(keyid text, parent_keyid text, level int, branch text);
  keyid | parent_keyid | level |      branch
-----+-----+-----+-----
row2   |              |      0 | row2
row4   | row2         |      1 | row2~row4
row6   | row4         |      2 | row2~row4~row6
row8   | row6         |      3 | row2~row4~row6~row8
row5   | row2         |      1 | row2~row5
row9   | row5         |      2 | row2~row5~row9
(6 rows)

-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
  AS t(keyid text, parent_keyid text, level int);
  keyid | parent_keyid | level
-----+-----+-----
row2   |              |      0
row4   | row2         |      1
row6   | row4         |      2
row8   | row6         |      3
row5   | row2         |      1
row9   | row5         |      2
(6 rows)

-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~')
  AS t(keyid text, parent_keyid text, level int, branch text, pos int);
  keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2   |              |      0 | row2              | 1
row5   | row2         |      1 | row2~row5         | 2
row9   | row5         |      2 | row2~row5~row9    | 3
row4   | row2         |      1 | row2~row4         | 4
row6   | row4         |      2 | row2~row4~row6    | 5
row8   | row6         |      3 | row2~row4~row6~row8 | 6
(6 rows)

-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)

```

```

AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2  |                |      0 |    1
row5  | row2           |      1 |    2
row9  | row5           |      2 |    3
row4  | row2           |      1 |    4
row6  | row4           |      2 |    5
row8  | row6           |      3 |    6
(6 rows)

```

## F.29.2. Author

Joe Conway

## F.30. test\_parser

`test_parser` is an example of a custom parser for full-text search. It doesn't do anything especially useful, but can serve as a starting point for developing your own parser.

`test_parser` recognizes words separated by white space, and returns just two token types:

```

mydb=# SELECT * FROM ts_token_type('testparser');
 tokid | alias | description
-----+-----+-----
      3 | word  | Word
     12 | blank | Space symbols
(2 rows)

```

These token numbers have been chosen to be compatible with the default parser's numbering. This allows us to use its `headline()` function, thus keeping the example simple.

### F.30.1. Usage

Running the installation script creates a text search parser `testparser`. It has no user-configurable parameters.

You can test the parser with, for example,

```

mydb=# SELECT * FROM ts_parse('testparser', 'That"s my first own parser');
 tokid | token
-----+-----
      3 | That's
     12 |
      3 | my
     12 |

```

```

3 | first
12 |
3 | own
12 |
3 | parser

```

Real-world use requires setting up a text search configuration that uses the parser. For example,

```

mydb=# CREATE TEXT SEARCH CONFIGURATION testcfg ( PARSER = testparser );
CREATE TEXT SEARCH CONFIGURATION

```

```

mydb=# ALTER TEXT SEARCH CONFIGURATION testcfg
mydb=#   ADD MAPPING FOR word WITH english_stem;
ALTER TEXT SEARCH CONFIGURATION

```

```

mydb=# SELECT to_tsvector('testcfg', 'That"s my first own parser');
           to_tsvector
-----

```

```

'that':1 'first':3 'parser':5
(1 row)

```

```

mydb=# SELECT ts_headline('testcfg', 'Supernovae stars are the brightest phenomena in galax
mydb=#           to_tsquery('testcfg', 'star'));
           ts_headline
-----

```

```

Supernovae <b>stars</b> are the brightest phenomena in galaxies
(1 row)

```

## F.31. tsearch2

The `tsearch2` module provides backwards-compatible text search functionality for applications that used `contrib/tsearch2` before text searching was integrated into core PostgreSQL in release 8.3.

### F.31.1. Portability Issues

Although the built-in text search features were based on `contrib/tsearch2` and are largely similar to it, there are numerous small differences that will create portability issues for existing applications:

- Some functions' names were changed, for example `rank` to `ts_rank`. The replacement `tsearch2` module provides aliases having the old names.
- The built-in text search data types and functions all exist within the system schema `pg_catalog`. In an installation using `contrib/tsearch2`, these objects would usually have been in the `public` schema, though some users chose to place them in a separate schema of their own. Explicitly schema-qualified references to the objects will therefore fail in either case. The replacement `tsearch2` module provides

alias objects that are stored in `public` (or another schema if necessary) so that such references will still work.

- There is no concept of a “current parser” or “current dictionary” in the built-in text search features, only of a current search configuration (set by the `default_text_search_config` parameter). While the current parser and current dictionary were used only by functions intended for debugging, this might still pose a porting obstacle in some cases. The replacement `tsearch2` module emulates these additional state variables and provides backwards-compatible functions for setting and retrieving them.

There are some issues that are not addressed by the replacement `tsearch2` module, and will therefore require application code changes in any case:

- The old `tsearch2` trigger function allowed items in its argument list to be names of functions to be invoked on the text data before it was converted to `tsvector` format. This was removed as being a security hole, since it was not possible to guarantee that the function invoked was the one intended. The recommended approach if the data must be massaged before being indexed is to write a custom trigger that does the work for itself.
- Text search configuration information has been moved into core system catalogs that are noticeably different from the tables used by `contrib/tsearch2`. Any applications that examined or modified those tables will need adjustment.
- If an application used any custom text search configurations, those will need to be set up in the core catalogs using the new text search configuration SQL commands. The replacement `tsearch2` module offers a little bit of support for this by making it possible to load an old set of `contrib/tsearch2` configuration tables into PostgreSQL 8.3. (Without the module, it is not possible to load the configuration data because values in the `regprocedure` columns cannot be resolved to functions.) While those configuration tables won’t actually *do* anything, at least their contents will be available to be consulted while setting up an equivalent custom configuration in 8.3.
- The old `reset_tsearch()` and `get_covers()` functions are not supported.
- The replacement `tsearch2` module does not define any alias operators, relying entirely on the built-in ones. This would only pose an issue if an application used explicitly schema-qualified operator names, which is very uncommon.

## F.31.2. Converting a pre-8.3 Installation

The recommended way to update a pre-8.3 installation that uses `contrib/tsearch2` is:

1. Make a dump from the old installation in the usual way, but be sure not to use `-c` (`--clean`) option of `pg_dump` or `pg_dumpall`.
2. In the new installation, create empty database(s) and install the replacement `tsearch2` module into each database that will use text search. This must be done *before* loading the dump data! If your old installation had the `contrib/tsearch2` objects in a schema other than `public`, be sure to adjust the `tsearch2` installation script so that the replacement objects are created in that same schema.
3. Load the dump data. There will be quite a few errors reported due to failure to recreate the original `contrib/tsearch2` objects. These errors can be ignored, but this means you cannot restore the dump in a single transaction (eg, you cannot use `pg_restore`’s `-1` switch).

4. Examine the contents of the restored `contrib/tsearch2` configuration tables (`pg_ts_cfg` and so on), and create equivalent built-in text search configurations as needed. You may drop the old configuration tables once you've extracted all the useful information from them.
5. Test your application.

At a later time you may wish to rename application references to the alias text search objects, so that you can eventually uninstall the replacement `tsearch2` module.

### F.31.3. References

Tsearch2 Development Site <http://www.sai.msu.su/~megeera/postgres/gist/tsearch/V2/>

## F.32. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

This module depends on the OSSP UUID library, which can be found at <http://www.oss.org/pkg/lib/uuid/>.

### F.32.1. uuid-oss Functions

The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F-35. Functions for UUID Generation**

Function	Description
<code>uuid_generate_v1()</code>	This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc()</code>	This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.

Function	Description
<code>uuid_generate_v3(namespace uuid, name text)</code>	This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown below. (It could be any UUID in theory.) The name is an identifier in the selected namespace.
<code>uuid_generate_v4()</code>	This function generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5(namespace uuid, name text)</code>	This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

For example:

```
SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');
```

The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.

**Table F-36. Functions Returning UUID Constants**

<code>uuid_nil()</code>	A “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns()</code>	Constant designating the DNS namespace for UUIDs.
<code>uuid_ns_url()</code>	Constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid()</code>	Constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.)
<code>uuid_ns_x500()</code>	Constant designating the X.500 distinguished name (DN) namespace for UUIDs.

## F.32.2. Author

Peter Eisentraut <pete\_r\_e@gmx.net>

## F.33. vacuumlo

`vacuumlo` is a simple utility program that will remove any “orphaned” large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in `contrib/lo` (see Section F.14). `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

### F.33.1. Usage

```
vacuumlo [options] database [database2 ... databaseN]
```

All databases named on the command line are processed. Available options include:

`-v`

Write a lot of progress messages.

`-n`

Don’t remove anything, just show what would be done.

`-U username`

Username to connect as.

`-W`

Force `vacuumlo` to prompt for a password before connecting to a database.

This option is never essential, since `vacuumlo` will automatically prompt for a password if the server demands password authentication. However, `vacuumlo` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

`-h hostname`

Database server’s host.

`-p port`

Database server’s port.

### F.33.2. Method

First, it builds a temporary table which contains all of the OIDs of the large objects in that database.

It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table.

The remaining entries in the temp table identify orphaned LOs. These are removed.

### F.33.3. Author

Peter Mount <pete@retap.org.uk>

## F.34. xml2

The `xml2` module provides XPath querying and XSLT functionality.

### F.34.1. Deprecation notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in PostgreSQL 8.4 in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to [pgsql-hackers@postgresql.org](mailto:pgsql-hackers@postgresql.org) so that the deficiency can be addressed.

### F.34.2. Description of functions

These functions provide straightforward XML parsing and XPath queries. All arguments are of type `text`, so for brevity that is not shown.

**Table F-37. Functions**

<code>xml_is_well_formed(document)</code> returns bool	This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: before PostgreSQL 8.2, this function was called <code>xml_valid()</code> . That is the wrong name since validity and well-formedness have different meanings in XML. The old name is still available, but is deprecated.)
<code>xpath_string(document,query)</code> returns text <code>xpath_number(document,query)</code> returns float <code>xpath_bool(document,query)</code> returns bool	These functions evaluate the XPath query on the supplied document, and cast the result to the specified type.

<code>xpath_node_set (document, query, toptag, itemtag)</code>	<p>This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like: <code>&lt;toptag&gt;</code>  <code>&lt;itemtag&gt;Value 1</code> which could be an XML fragment <code>&lt;/itemtag&gt;</code>  <code>&lt;itemtag&gt;Value 2....&lt;/itemtag&gt;</code>  <code>&lt;/toptag&gt;</code></p> <p>If either toptag or itemtag is an empty string, the relevant tag is omitted.</p>
<code>xpath_node_set (document, query)</code> returns text	Like <code>xpath_node_set (document, query, toptag, itemtag)</code> but result omits both tags.
<code>xpath_node_set (document, query, itemtag)</code> returns text	Like <code>xpath_node_set (document, query, toptag, itemtag)</code> but result omits toptag.
<code>xpath_list (document, query, separator)</code> returns text	This function returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if separator is ,.
<code>xpath_list (document, query)</code> returns text	This is a wrapper for the above function that uses , as the separator.

### F.34.3. xpath\_table

`xpath_table (text key, text document, text relation, text xpaths, text criteria)` returns

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins.

**Table F-38. Parameters**

key	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e. it identifies the record from which each output row came (see note below about multiple values)
document	the name of the field containing the XML document
relation	the name of the table or view containing the documents
xpaths	one or more XPath expressions, separated by

criteria	the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation
----------	--

These parameters (except the XPath strings) are just substituted into a plain SQL `SELECT` statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this `SELECT` needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > "2003-01-01" ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be `NULL`.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn’t necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g. aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml,"/article/@date") > "2003-03-20" ')
    AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.34.3.1. Multivalued results

The `xpath_table` function assumes that the results of each XPath query might be multi-valued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, NULLs will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
  id int4 NOT NULL,
  xml text,
  CONSTRAINT pk PRIMARY KEY (id)
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
    '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int4, doc_num varchar(10), line_num varchar(10), val1 int4, val2 int4, val3 int4)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id','xml','test',
    '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
    'true')
  AS t(id int4, line_num varchar(10), val1 int4, val2 int4, val3 int4),
  xpath_table('id','xml','test','/doc/@num','true')
  AS i(id int4, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

```

id | line_num | val1 | val2 | val3 | doc_num
----+-----+-----+-----+-----+-----
 1 | L1      |    1 |    2 |    3 | C1
 1 | L2      |   11 |   22 |   33 | C1
(2 rows)

```

## F.34.4. XSLT functions

The following functions are available if libxslt is installed (this is not currently detected automatically, so you will have to amend the Makefile):

### F.34.4.1. `xslt_process`

```
xslt_process(text document, text stylesheet, text paramlist) returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The paramlist is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

Also note that if either the document or stylesheet values do not begin with a `<` then they will be treated as URLs and libxslt will fetch them. It follows that you can use `xslt_process` as a means to fetch the contents of URLs — you should be aware of the security implications of this.

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.34.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD licence as PostgreSQL.

## Appendix G. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

To help our community with the development of their external projects, we have created PgFoundry<sup>1</sup>, a website that provides hosting for PostgreSQL-related projects that are maintained outside the core PostgreSQL distribution. PgFoundry is built using the GForge software project and is similar to SourceForge.net<sup>2</sup> in its feature set, providing mailing lists, forums, bug tracking, CVS, and web hosting. If you have a PostgreSQL-related open source project that you would like to have hosted at PgFoundry, please feel free to create a new project.

### G.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ecpg is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. Table G-1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

**Table G-1. Externally Maintained Client Interfaces**

Name	Language	Comments	Website
DBD::Pg	Perl	Perl DBI driver	<a href="http://search.cpan.org/dist/DBD-Pg/">http://search.cpan.org/dist/DBD-Pg/</a>

## G.2. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/PgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. Table G-2 lists some of these packages. Note that some of these projects might not be released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

**Table G-2. Externally Maintained Procedural Languages**

Name	Language	Website
PL/Java	Java	<a href="http://pljava.projects.postgresql.org/">http://pljava.projects.postgresql.org/</a>

PL/sh	Unix shell	<a href="http://plsh.projects.postgresql.org/">http://plsh.projects.postgresql.org/</a>

## G.3. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are packaged with the database. The `contrib/` directory shipped with the

source code contains a large number of extensions. The `README` file in that directory contains a summary. They include conversion tools, full-text indexing, XML tools, and additional data types and indexing methods. Other extensions are developed independently, like PostGIS<sup>3</sup>. Even PostgreSQL replication solutions are developed externally. For example, Slony-I<sup>4</sup> is a popular master/slave replication solution that is developed independently from the core project.

There are several administration tools available for PostgreSQL. The most popular is pgAdmin III<sup>5</sup>, and there are several commercially available ones as well.

---

3. <http://www.postgis.org/>  
4. <http://www.slony.info>  
5. <http://www.pgadmin.org/>

# Appendix H. The CVS Repository

The PostgreSQL source code is stored and managed using the CVS version control system.

At least three methods, anonymous CVS, rsync, and CVSup, are available to pull the CVS code tree from the PostgreSQL server to your local machine. Our CVS Wiki, [http://wiki.postgresql.org/index.php/Working\\_with\\_CVS](http://wiki.postgresql.org/index.php/Working_with_CVS), has additional details on working with CVS.

## H.1. Getting The Source Via Anonymous CVS

If you would like to keep up with the current sources on a regular basis, you can fetch them from our CVS server and then use CVS to retrieve updates from time to time.

### Anonymous CVS

1. You will need a local copy of CVS (Concurrent Version Control System), which you can get from <http://www.nongnu.org/cvs/> (the official site with the latest version) or any GNU software archive site (often somewhat outdated). Many systems have a recent version of cvs installed by default.

2. Do an initial login to the CVS server:

```
cvs -d :pserver:anoncvs@anoncvs.postgresql.org:/projects/cvsroot login
```

You will be prompted for a password; you can enter anything except an empty string.

You should only need to do this once, since the password will be saved in `.cvspass` in your home directory.

3. Fetch the PostgreSQL sources:

```
cvs -z3 -d :pserver:anoncvs@anoncvs.postgresql.org:/projects/cvsroot co -P pgsql
```

This installs the PostgreSQL sources into a subdirectory `pgsql` of the directory you are currently in.

**Note:** If you have a fast link to the Internet, you might not need `-z3`, which instructs CVS to use `gzip` compression for transferred data. But on a modem-speed link, it's a very substantial win.

This initial checkout is a little slower than simply downloading a `tar.gz` file; expect it to take 40 minutes or so if you have a 28.8K modem. The advantage of CVS doesn't show up until you want to update the file set later on.

4. Whenever you want to update to the latest CVS sources, `cd` into the `pgsql` subdirectory, and issue:

```
cvs -z3 update -d -P
```

This will fetch only the changes since the last time you updated. You can update in just a couple of minutes, typically, even over a modem-speed line.

5. You can save yourself some typing by making a file `.cvsrc` in your home directory that contains:

```
cvs -z3
update -d -P
```

This supplies the `-z3` option to all `cvs` commands, and the `-d` and `-P` options to `cvs update`. Then you just have to say:

```
cvs update
to update your files.
```

CVS can do a lot of other things, such as fetching prior revisions of the PostgreSQL sources rather than the latest development version. For more info consult the manual that comes with CVS, or see the online documentation at <http://www.nongnu.org/cvs/>.

CVS has deficiencies. For example, generating diffs that add or remove files requires write access to the CVS repository. To work around that deficiency, use `cvsutils`, which is packaged in several operating systems, and is available in source form at <http://www.red-bean.com/cvsutils/>.

Note that building PostgreSQL from a CVS pull requires reasonably up-to-date versions of `bison` and `flex`, which are not needed to build from a distribution tarball because the files made with them are pre-built in a tarball. Otherwise the tool requirements are the same as building from source.

## H.2. CVS Tree Organization

**Author:** Written by Marc G. Fournier (<[scrappy@hub.org](mailto:scrappy@hub.org)>) on 1998-11-05

The command `cvs checkout` has a flag, `-r`, that lets you check out a certain revision of a module. This flag makes it easy to, for example, retrieve the sources that make up release 6\_4 of the module ‘tc’ at any time in the future:

```
cvs checkout -r REL6_4 tc
```

This is useful, for instance, if someone claims that there is a bug in that release, but you cannot find the bug in the current working copy.

**Tip:** You can also check out a module as it was at any given date using the `-D` option.

When you tag more than one file with the same tag you can think about the tag as “a curve drawn through a matrix of file name vs. revision number”. Say we have 5 files with the following revisions:

file1	file2	file3	file4	file5	
1.1	1.1	1.1	1.1	/--1.1*	<-*-- TAG
1.2*-	1.2	1.2	-1.2*-		
1.3 \-	1.3*-	1.3	/ 1.3		

```

1.4          \  1.4  /  1.4
              \-1.5*-  1.5
                1.6

```

then the tag `TAG` will reference file1-1.2, file2-1.3, etc.

**Note:** For creating a release branch, other than a `-b` option added to the command, it's the same thing.

So, to create the 6.4 release I did the following:

```

cd pgsql
cvs tag -b REL6_4

```

which will create the tag and the branch for the RELEASE tree.

For those with CVS access, it's simple to create directories for different versions. First, create two subdirectories, RELEASE and CURRENT, so that you don't mix up the two. Then do:

```

cd RELEASE
cvs checkout -P -r REL6_4 pgsql
cd ../CURRENT
cvs checkout -P pgsql

```

which results in two directory trees, RELEASE/pgsql and CURRENT/pgsql. From that point on, CVS will keep track of which repository branch is in which directory tree, and will allow independent updates of either tree.

If you are *only* working on the CURRENT source tree, you just do everything as before we started tagging release branches.

After you've done the initial checkout on a branch:

```

cvs checkout -r REL6_4

```

anything you do within that directory structure is restricted to that branch. If you apply a patch to that directory structure and do a:

```

cvs commit

```

while inside of it, the patch is applied to the branch and *only* the branch.

## H.3. Getting The Source Via rsync

An alternative to using anonymous CVS for retrieving the PostgreSQL source tree is rsync, an incremental file transfer tool. A major advantage to using rsync is that it can reliably replicate the *entire* CVS repository on your local system, allowing fast local access to cvs operations such as `log` and `diff`. Other advantages

include fast synchronization to the PostgreSQL server due to an efficient streaming transfer protocol which only sends the changes since the last update.

You can download the CVS repository using this command:

```
rsync -avzCH --delete anoncvs.postgresql.org::pgsql-cvs cvsroot/
```

For full instructions, see the "rsync" section in the `pgbuildfarm` instructions<sup>1</sup>.

## H.4. Getting The Source Via CVSup

Another alternative to using anonymous CVS for retrieving the PostgreSQL source tree is CVSup. CVSup was developed by John Polstra (<jdp@polstra.com>) to distribute CVS repositories and other file trees for the FreeBSD project<sup>2</sup>.

### H.4.1. Preparing A CVSup Client System

Two directory areas are required for CVSup to do its job: a local CVS repository (or simply a directory area if you are fetching a snapshot rather than a repository; see below) and a local CVSup bookkeeping area. These can coexist in the same directory tree.

Decide where you want to keep your local copy of the CVS repository. On one of our systems we recently set up a repository in `/home/cvs/`, but had formerly kept it under a PostgreSQL development tree in `/opt/postgres/cvs/`. If you intend to keep your repository in `/home/cvs/`, then put:

```
setenv CVSROOT /home/cvs
```

in your `.cshrc` file, or a similar line in your `.bashrc` or `.profile` file, depending on your shell.

The cvs repository area must be initialized. Once `CVSROOT` is set, then this can be done with a single command:

```
cvs init
```

after which you should see at least a directory named `CVSROOT` when listing the `CVSROOT` directory:

```
$ ls $CVSROOT
CVSROOT/
```

### H.4.2. Running a CVSup Client

Verify that `cvsup` is in your path; on most systems you can do this by typing:

```
which cvsup
```

- 
1. <http://pgfoundry.org/docman/view.php/1000040/4/PGBuildFarm-HOWTO.txt>
  2. <http://www.freebsd.org>

Then, simply run `cvsup` using:

```
cvsup -L 2 postgres.cvsup
```

where `-L 2` enables some status messages so you can monitor the progress of the update, and `postgres.cvsup` is the path and name you have given to your CVSup configuration file.

Here is a CVSup configuration file modified for a specific installation, and which maintains a full local CVS repository:

```
# This file represents the standard CVSup distribution file
# for the PostgreSQL ORDBMS project
# Modified by lockhart@fourpalms.org 1997-08-28
# - Point to my local snapshot source tree
# - Pull the full CVS repository, not just the latest snapshot
#
# Defaults that apply to all the collections
*default host=cvsup.postgresql.org
*default compress
*default release=cvs
*default delete use-rel-suffix
# enable the following line to get the latest snapshot
#*default tag=.
# enable the following line to get whatever was specified above or by default
# at the date specified below
#*default date=97.08.29.00.00.00

# base directory where CVSup will store its 'bookmarks' file(s)
# will create subdirectory sup/
#*default base=/opt/postgres # /usr/local/pgsql
*default base=/home/cvs

# prefix directory where CVSup will store the actual distribution(s)
*default prefix=/home/cvs

# complete distribution, including all below
pgsql

# individual distributions vs 'the whole thing'
# pgsql-doc
# pgsql-perl5
# pgsql-src
```

If you specify `repository` instead of `pgsql` in the above setup, you will get a complete copy of the entire repository at `cvsup.postgresql.org`, including its `CVSROOT` directory. If you do that, you will probably want to exclude those files in that directory that you want to modify locally, using a `refuse` file. For example, for the above setup you might put this in `/home/cvs/sup/repository/refuse`:

```
CVSROOT/config*
CVSROOT/commitinfo*
CVSROOT/logininfo*
```

See the CVSup manual pages for how to use refuse files.

The following is a suggested CVSup configuration file from the PostgreSQL ftp site<sup>3</sup> which will fetch the current snapshot only:

```
# This file represents the standard CVSup distribution file
# for the PostgreSQL ORDBMS project
#
# Defaults that apply to all the collections
*default host=cvsup.postgresql.org
*default compress
*default release=cvs
*default delete use-rel-suffix
*default tag=.

# base directory where CVSup will store its 'bookmarks' file(s)
*default base=/usr/local/pgsql

# prefix directory where CVSup will store the actual distribution(s)
*default prefix=/usr/local/pgsql

# complete distribution, including all below
pgsql

# individual distributions vs 'the whole thing'
# pgsql-doc
# pgsql-perl5
# pgsql-src
```

---

3. <ftp://ftp.postgresql.org/pub/CVSup/README.cvsup>

# Appendix I. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF or PostScript, for printing
- man pages, for quick reference.

Additionally, a number of plain-text `README` files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF and PostScript format documentation is available separately for download.

## I.1. DocBook

The documentation sources are written in *DocBook*, which is a markup language superficially similar to HTML. Both of these languages are applications of the *Standard Generalized Markup Language*, SGML, which is essentially a language for describing other languages. In what follows, the terms DocBook and SGML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group<sup>1</sup>. The official DocBook site<sup>2</sup> has good introductory and reference documentation and a complete O'Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide<sup>3</sup> is very helpful for beginners. The FreeBSD Documentation Project<sup>4</sup> also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

## I.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD<sup>5</sup>

This is the definition of DocBook itself. We currently use version 4.2; you cannot use later or earlier

- 
1. <http://www.oasis-open.org>
  2. <http://www.oasis-open.org/docbook>
  3. <http://newbiedoc.sourceforge.net/metadoc/docbook-guide.html>
  4. <http://www.freebsd.org/docproj/docproj.html>
  5. <http://www.oasis-open.org/docbook/sgml/>

versions. Note that there is also an XML version of DocBook — do not use that.

#### ISO 8879 character entities<sup>6</sup>

These are required by DocBook but are distributed separately because they are maintained by ISO.

#### OpenJade<sup>7</sup>

This is the base package of SGML processing. It contains an SGML parser, a DSSSL processor (that is, a program to convert SGML to other formats using DSSSL stylesheets), as well as a number of related tools. Jade is now being maintained by the OpenJade group, no longer by James Clark.

#### DocBook DSSSL Stylesheets<sup>8</sup>

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

#### DocBook2X tools<sup>9</sup>

This optional package is used to create man pages. It has a number of prerequisite packages of its own. Check the web site.

#### JadeTeX<sup>10</sup>

If you want to, you can also install JadeTeX to use TeX as a formatting backend for Jade. JadeTeX can create PostScript or PDF files (the latter with bookmarks).

However, the output from JadeTeX is inferior to what you get from the RTF backend. Particular problem areas are tables and various artifacts of vertical and horizontal spacing. Also, there is no opportunity to manually polish the results.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

## I.2.1. Linux RPM Installation

Most vendors provide a complete RPM set for DocBook processing in their distribution. Look for an “SGML” option while installing, or the following packages: `sgml-common`, `docbook`, `stylesheets`, `openjade` (or `jade`). Possibly `sgml-tools` will be needed as well. If your distributor does not provide these then you should be able to make use of the packages from some other, reasonably compatible vendor.

## I.2.2. FreeBSD Installation

The FreeBSD Documentation Project is itself a heavy user of DocBook, so it comes as no surprise that there is a full set of “ports” of the documentation tools available on FreeBSD. The following ports need

---

6. <http://www.oasis-open.org/cover/ISOEnts.zip>

7. <http://openjade.sourceforge.net>

8. <http://docbook.sourceforge.net/projects/dsssl/index.html>

9. <http://docbook2x.sourceforge.net>

10. <http://jadetex.sourceforge.net>

to be installed to build the documentation on FreeBSD.

- `textproc/sp`
- `textproc/openjade`
- `textproc/iso8879`
- `textproc/dsssl-docbook-modular`
- `textproc/docbook-420`

A number of things from `/usr/ports/print` (`tex`, `jadetex`) might also be of interest.

It's possible that the ports do not update the main catalog file in `/usr/local/share/sgml/catalog.ports` or order isn't proper. Be sure to have the following lines in beginning of file:

```
CATALOG "openjade/catalog"
CATALOG "iso8879/catalog"
CATALOG "docbook/dsssl/modular/catalog"
CATALOG "docbook/4.2/catalog"
```

If you do not want to edit the file you can also set the environment variable `SGML_CATALOG_FILES` to a colon-separated list of catalog files (such as the one above).

More information about the FreeBSD documentation tools can be found in the FreeBSD Documentation Project's instructions<sup>11</sup>.

### I.2.3. Debian Packages

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install openjade1.3
apt-get install docbook
apt-get install docbook-dsssl
```

(The plain `openjade` package installs OpenJade 1.4, which seems not to work.)

### I.2.4. Manual Installation from Source

The manual installation process of the DocBook tools is somewhat complex, so if you have pre-built packages available, use them. We describe here only a standard setup, with reasonably standard installation paths, and no “fancy” features. For details, you should study the documentation of the respective package, and read SGML introductory material.

---

11. [http://www.freebsd.org/doc/en\\_US.ISO8859-1/books/fdp-primer/tools.html](http://www.freebsd.org/doc/en_US.ISO8859-1/books/fdp-primer/tools.html)

### I.2.4.1. Installing OpenJade

1. The installation of OpenJade offers a GNU-style `./configure`; `make`; `make install` build process. Details can be found in the OpenJade source distribution. In a nutshell:

```
./configure --enable-default-catalog=/usr/local/share/sgml/catalog
make
make install
```

Be sure to remember where you put the “default catalog”; you will need it below. You can also leave it off, but then you will have to set the environment variable `SGML_CATALOG_FILES` to point to the file whenever you use `jade` later on. (This method is also an option if OpenJade is already installed and you want to install the rest of the tool chain locally.)

2. Additionally, you should install the files `dsssl.dtd`, `fot.dtd`, `style-sheet.dtd`, and `catalog` from the `dsssl` directory somewhere, perhaps into `/usr/local/share/sgml/dsssl`. It’s probably easiest to copy the entire directory:

```
cp -R dsssl /usr/local/share/sgml
```

3. Finally, create the file `/usr/local/share/sgml/catalog` and add this line to it:

```
CATALOG "dsssl/catalog"
```

(This is a relative path reference to the file installed in step 2. Be sure to adjust it if you chose your installation layout differently.)

### I.2.4.2. Installing the DocBook DTD Kit

1. Obtain the DocBook V4.2 distribution<sup>12</sup>.
2. Create the directory `/usr/local/share/sgml/docbook-4.2` and change to it. (The exact location is irrelevant, but this one is reasonable within the layout we are following here.)

```
$ mkdir /usr/local/share/sgml/docbook-4.2
$ cd /usr/local/share/sgml/docbook-4.2
```

3. Unpack the archive.

```
$ unzip -a ...../docbook-4.2.zip
```

(The archive will unpack its files into the current directory.)

4. Edit the file `/usr/local/share/sgml/catalog` (or whatever you told `jade` during installation) and put a line like this into it:

```
CATALOG "docbook-4.2/docbook.cat"
```

5. Download the ISO 8879 character entities archive<sup>13</sup>, unpack it, and put the files in the same directory you put the DocBook files in.

```
$ cd /usr/local/share/sgml/docbook-4.2
$ unzip ...../ISOEnts.zip
```

6. Run the following command in the directory with the DocBook and ISO files:

```
perl -pi -e 's/iso-(.*)\.gml/ISO\1/g' docbook.cat
```

12. <http://www.docbook.org/sgml/4.2/docbook-4.2.zip>

13. <http://www.oasis-open.org/cover/ISOEnts.zip>

(This fixes a mixup between the names used in the DocBook catalog file and the actual names of the ISO character entity files.)

### I.2.4.3. Installing the DocBook DSSSL Style Sheets

To install the style sheets, unzip and untar the distribution and move it to a suitable place, for example `/usr/local/share/sgml`. (The archive will automatically create a subdirectory.)

```
$ gunzip docbook-dsssl-1.xx.tar.gz
$ tar -C /usr/local/share/sgml -xf docbook-dsssl-1.xx.tar
```

The usual catalog entry in `/usr/local/share/sgml/catalog` can also be made:

```
CATALOG "docbook-dsssl-1.xx/catalog"
```

Because stylesheets change rather often, and it's sometimes beneficial to try out alternative versions, PostgreSQL doesn't use this catalog entry. See Section I.2.5 for information about how to select the stylesheets instead.

### I.2.4.4. Installing JadeTeX

To install and use JadeTeX, you will need a working installation of TeX and LaTeX2e, including the supported tools and graphics packages, Babel, AMS fonts and AMS-LaTeX, the PSNFSS extension and companion kit of “the 35 fonts”, the dvips program for generating PostScript, the macro packages fancyhdr, hyperref, minitoc, url and ot2enc. All of these can be found on your friendly neighborhood CTAN site<sup>14</sup>. The installation of the TeX base system is far beyond the scope of this introduction. Binary packages should be available for any system that can run TeX.

Before you can use JadeTeX with the PostgreSQL documentation sources, you will need to increase the size of TeX's internal data structures. Details on this can be found in the JadeTeX installation instructions.

Once that is finished you can install JadeTeX:

```
$ gunzip jadetex-xxx.tar.gz
$ tar xf jadetex-xxx.tar
$ cd jadetex
$ make install
$ mktexlsr
```

The last two need to be done as root.

---

14. <http://www.ctan.org>

### I.2.5. Detection by `configure`

Before you can build the documentation you need to run the `configure` script as you would when building the PostgreSQL programs themselves. Check the output near the end of the run, it should look something like this:

```
checking for onsgmls... onsgmls
checking for openjade... openjade
checking for DocBook V4.2... yes
checking for DocBook stylesheets... /usr/lib/sgml/stylesheets/nwalsh-modular
checking for sgmlspl... sgmlspl
```

If neither `onsgmls` nor `nsgmls` were found then you will not see the remaining 4 lines. `nsgmls` is part of the Jade package. You can pass the environment variables `JADE` and `NSGMLS` to `configure` to point to the programs if they are not found automatically. If “DocBook V4.2” was not found then you did not install the DocBook DTD kit in a place where Jade can find it, or you have not set up the catalog files correctly. See the installation hints above. The DocBook stylesheets are looked for in a number of relatively standard places, but if you have them some other place then you should set the environment variable `DOCBOOKSTYLE` to the location and rerun `configure` afterwards.

## I.3. Building The Documentation

Once you have everything set up, change to the directory `doc/src/sgml` and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU `make`.)

### I.3.1. HTML

To build the HTML version of the documentation:

```
doc/src/sgml$ gmake html
```

This is also the default target.

To create a proper index, the build might process several identical stages. If you do not care about the index, and just want to proof-read the output, use `draft`:

```
doc/src/sgml$ gmake draft
```

To allow for easier handling in the final distribution, the files comprising the HTML documentation can be stored in a tar archive that is unpacked at installation time. To create the HTML documentation package, use the commands:

```
cd doc/src
gmake postgres.tar.gz
```

In the distribution, these archives live in the `doc` directory and are installed by default with `gmake install`.

### I.3.2. Manpages

We use the `docbook2man` utility to convert DocBook `refentry` pages to `*roff` output suitable for man pages. The man pages are also distributed as a tar archive, similar to the HTML version. To create the man page package, use the commands:

```
cd doc/src
gmake man.tar.gz
```

which will result in a tar file being generated in the `doc/src` directory.

To generate quality man pages, it might be necessary to use a hacked version of the conversion utility or do some manual postprocessing. All man pages should be manually inspected before distribution.

### I.3.3. Print Output via JadeTeX

If you want to use JadeTeX to produce a printable rendition of the documentation, you can use one of the following commands:

- To generate PostScript via DVI in A4 format:

```
doc/src/sgml$ gmake postgres-A4.ps
```

In U.S. letter format:

```
doc/src/sgml$ gmake postgres-US.ps
```

- To make a PDF:

```
doc/src/sgml$ gmake postgres-A4.pdf
```

or

```
doc/src/sgml$ gmake postgres-US.pdf
```

(Of course you can also make a PDF version from the PostScript, but if you generate PDF directly, it will have hyperlinks and other enhanced features.)

When using JadeTeX to build the PostgreSQL documentation, you will probably need to increase some of TeX's internal parameters. These can be set in the file `texmf.cnf`. The following settings worked at the time of this writing:

```
hash_extra.jadetex = 200000
hash_extra.pdfjadetex = 200000
pool_size.jadetex = 2000000
pool_size.pdfjadetex = 2000000
string_vacancies.jadetex = 150000
string_vacancies.pdfjadetex = 150000
max_strings.jadetex = 300000
max_strings.pdfjadetex = 300000
save_size.jadetex = 15000
save_size.pdfjadetex = 15000
```

### I.3.4. Print Output via RTF

You can also create a printable version of the PostgreSQL documentation by converting it to RTF and applying minor formatting corrections using an office suite. Depending on the capabilities of the particular office suite, you can then convert the documentation to PostScript or PDF. The procedure below illustrates this process using Applixware.

**Note:** It appears that current versions of the PostgreSQL documentation trigger some bug in or exceed the size limit of OpenJade. If the build process of the RTF version hangs for a long time and the output file still has size 0, then you might have hit that problem. (But keep in mind that a normal build takes 5 to 10 minutes, so don't abort too soon.)

#### Applixware RTF Cleanup

OpenJade omits specifying a default style for body text. In the past, this undiagnosed problem led to a long process of table of contents generation. However, with great help from the Applixware folks the symptom was diagnosed and a workaround is available.

1. Generate the RTF version by typing:

```
doc/src/sgml$ gmake postgres.rtf
```

2. Repair the RTF file to correctly specify all styles, in particular the default style. If the document contains `refentry` sections, one must also replace formatting hints which tie a preceding paragraph to the current paragraph, and instead tie the current paragraph to the following one. A utility, `fixrtf`, is available in `doc/src/sgml` to accomplish these repairs:

```
doc/src/sgml$ ./fixrtf --refentry postgres.rtf
```

The script adds `{\s0 Normal;}` as the zeroth style in the document. According to Applixware, the RTF standard would prohibit adding an implicit zeroth style, though Microsoft Word happens to handle this case. For repairing `refentry` sections, the script replaces `\keepn` tags with `\keep`.

3. Open a new document in Applixware Words and then import the RTF file.
4. Generate a new table of contents (ToC) using Applixware.
  - a. Select the existing ToC lines, from the beginning of the first character on the first line to the last character of the last line.
  - b. Build a new ToC using Tools→Book Building→Create Table of Contents. Select the first three levels of headers for inclusion in the ToC. This will replace the existing lines imported in the RTF with a native Applixware ToC.
  - c. Adjust the ToC formatting by using Format→Style, selecting each of the three ToC styles, and adjusting the indents for `First` and `Left`. Use the following values:

Style	First Indent (inches)	Left Indent (inches)
TOC-Heading 1	0.4	0.4
TOC-Heading 2	0.8	0.8
TOC-Heading 3	1.2	1.2

5. Work through the document to:
  - Adjust page breaks.
  - Adjust table column widths.
6. Replace the right-justified page numbers in the Examples and Figures portions of the ToC with correct values. This only takes a few minutes.
7. Delete the index section from the document if it is empty.
8. Regenerate and adjust the table of contents.
  - a. Select the ToC field.
  - b. Select Tools→Book Building→Create Table of Contents.
  - c. Unbind the ToC by selecting Tools→Field Editing→Unprotect.
  - d. Delete the first line in the ToC, which is an entry for the ToC itself.
9. Save the document as native Applixware Words format to allow easier last minute editing later.
10. “Print” the document to a file in PostScript format.

### I.3.5. Plain Text Files

Several files are distributed as plain text, for reading during the installation process. The `INSTALL` file corresponds to Chapter 15, with some minor changes to account for the different context. To recreate the file, change to the directory `doc/src/sgml` and enter **gmake INSTALL**. This will create a file `INSTALL.html` that can be saved as text with Netscape Navigator and put into the place of the existing file. Netscape seems to offer the best quality for HTML to text conversions (over lynx and w3m).

The file `HISTORY` can be created similarly, using the command **gmake HISTORY**. For the file `src/test/regress/README` the command is **gmake regress\_README**.

### I.3.6. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

```
doc/src/sgml$ gmake check
```

## I.4. Documentation Authoring

SGML and DocBook do not suffer from an oversupply of open-source authoring tools. The most common tool set is the Emacs/XEmacs editor with appropriate editing mode. On some systems these tools are provided in a typical full installation.

### I.4.1. Emacs/PSGML

PSGML is the most common and most powerful mode for editing SGML documents. When properly configured, it will allow you to use Emacs to insert tags and check markup consistency. You could use it for HTML as well. Check the PSGML web site<sup>15</sup> for downloads, installation instructions, and detailed documentation.

There is one important thing to note with PSGML: its author assumed that your main SGML DTD directory would be `/usr/local/lib/sgml`. If, as in the examples in this chapter, you use `/usr/local/share/sgml`, you have to compensate for this, either by setting `SGML_CATALOG_FILES` environment variable, or you can customize your PSGML installation (its manual tells you how).

Put the following in your `~/.emacs` environment file (adjusting the path names to be appropriate for your system):

```
; ***** for SGML mode (psgml)

(setq sgml-omittag t)
(setq sgml-shorttag t)
(setq sgml-minimize-attributes nil)
(setq sgml-always-quote-attributes t)
(setq sgml-indent-step 1)
(setq sgml-indent-data t)
(setq sgml-parent-document nil)
(setq sgml-default-dtd-file "./reference.ced")
(setq sgml-exposed-tags nil)
(setq sgml-catalog-files '("/usr/local/share/sgml/catalog"))
(setq sgml-ecat-files nil)

(autoload 'sgml-mode "psgml" "Major mode to edit SGML files." t )
```

and in the same file add an entry for SGML into the (existing) definition for `auto-mode-alist`:

```
(setq
  auto-mode-alist
  ' (("\\.sgml$" . sgml-mode)
    )
)
```

The PostgreSQL distribution includes a parsed DTD definitions file `reference.ced`. You might find that when using PSGML, a comfortable way of working with these separate files of book parts is to insert a proper `DOCTYPE` declaration while you're editing them. If you are working on this source, for instance,

---

15. [http://www.lysator.liu.se/projects/about\\_psgml.html](http://www.lysator.liu.se/projects/about_psgml.html)

it is an appendix chapter, so you would specify the document as an “appendix” instance of a DocBook document by making the first line look like this:

```
<!DOCTYPE appendix PUBLIC "-//OASIS//DTD DocBook V4.2//EN">
```

This means that anything and everything that reads SGML will get it right, and I can verify the document with `nsgmls -s docguide.sgml`. (But you need to take out that line before building the entire documentation set.)

## I.4.2. Other Emacs modes

GNU Emacs ships with a different SGML mode, which is not quite as powerful as PSGML, but it’s less confusing and lighter weight. Also, it offers syntax highlighting (font lock), which can be very helpful.

Norm Walsh offers a major mode<sup>16</sup> specifically for DocBook which also has font-lock and a number of features to reduce typing.

# I.5. Style Guide

## I.5.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

### Name

This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

### Synopsis

This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

### Description

Several paragraphs explaining what the command does.

### Options

A list describing each command-line option. If there are a lot of options, subsections can be used.

16. <http://nwalsh.com/emacs/docbookide/index.html>

## Exit Status

If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

## Usage

Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

## Environment

List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like `SHELL` might be of interest to the user.

## Files

List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

## Diagnostics

Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.

## Notes

Anything that doesn't fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

## Examples

Examples

## History

If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.

## See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.

# Appendix J. Acronyms

This is a list of acronyms commonly used in the PostgreSQL documentation and in discussions about PostgreSQL.
