

# Introducing KeyJnote

Martin J. Fiedler

version 0.10

<http://keyjnote.sourceforge.net/>

# What is KeyJnote?

## **KeyJnote is a PDF and image viewer optimized for presentations.**

- ... with some eye candy ;)
- uses OpenGL for display
- uses Xpdf or GhostScript to render PDF files
- written in Python
- available for Unix-like and Windows operating systems
- Open Source, licensed under GPL

# Software Requirements

KeyJnote requires a few libraries and helper applications:

- Python 2.3 or newer
- PyGame (SDL port for Python)
- PyOpenGL
- Python Imaging Library (PIL)
- Xpdf or GhostScript
- pdftk (*optional*)

Packages for these dependencies should be able for almost every operating system.

For Windows, there's a convenient self-contained archive with everything needed.

# Hardware Requirements

- hardware accelerated OpenGL
  - every post-2000 graphics chip should do
  - Linux/BSD users need a driver that actually implements hardware acceleration!
- a fast CPU
  - some transitions are quite CPU-intensive
  - rule of thumb: the faster the better!
  - absolute minimum is at about 700 MHz

# How does it work?

- 1 create slides with the presentation software of your choice
- 2 export them to a PDF file
- 3 `keyjnote MySlides.pdf`
  - left mouse button, [PageDown] or [Space]: next slide
  - right mouse button, [PageUp] or [Backspace]: previous slide
  - [Q] or [Esc]: quit

# Emphasis

KeyJnote offers multiple ways of emphasizing parts of a page.

## Option 1: „Spotlight“

- toggle with [Enter]
- a bright circular spot follows the mouse cursor
- everything else gets dark and blurry
- spot size adjustable with [+]/[-] or the mouse wheel

# Highlight Boxes and Zoom

## Option 2: Highlight Boxes

- drag a box with the left mouse button
- any number of boxes per page
- delete a box by clicking it with the right mouse button
- boxes stay even after leaving and re-entering the page

## Option 3: Zoom

- [Z] key toggles 2x zoom
- visible image can be moved around with the right mouse button

# Overview Page

- press the [Tab] key
- KeyJnote zooms back to an overview screen showing all pages of the presentation
- new page can be selected with mouse or keyboard
- left mouse button or [Enter] zooms into selected page
- right mouse button or [Tab] cancels and returns to the previously shown page

# Customization

- command line parameters (lots of them!)
- „Info Scripts“
  - same name as the input file, but suffix `.info`, e.g. `slides.pdf` → `slides.pdf.info`
  - real Python scripts, executed before the presentation starts
  - can be used to set the document title or other settings
  - can be used to set up per-page settings: „Page Properties“
    - title
    - transition effect
    - ...

# Info Script Example

```
# -*- coding: iso8859-1 -*-

DocumentTitle = "Example Presentation"

PageProps = {
    1: { 'title': 'Title Page',
        'transition': PagePeel },
    2: { 'title': 'Introduction' },
    5: { 'timeout': 3500 },
    8: { 'overview': False }
}
```

# Other Features

- instead of PDF files, KeyJnote can also show images (JPEG, PNG)
- page cache in RAM or on disk
- background rendering
- fade to black or white
- hide specific pages from the overview page
- page bookmarks (keyboard shortcuts)
- only show a subset of the presentation
- rotation in 90-degree steps
- time display and measurement

# Rarely Used Features

- automatic, timed presentations
- customization of virtually every timing or OSD parameter
- automatic reloading of the input file(s) on change
- permanent storage of the highlight boxes
- playing sounds or executing arbitrary Python code when entering a page
- „Render Mode“: doesn't show the presentation, but renders the input PDF file in a directory with one PNG file per page

# Missing Features

- support for hyperlinks inside the document
  - used by latex-beamer for navigation:  

  - Problem: no possibility to extract the hyperlinks from the PDF file :(
- painting and annotations
- multi-monitor support
- video support
- integration into (or cooperation with) latex-beamer
- *your feature here*
